I must express my gratitude, first to the Council of the Royal College of Surgeons of England for permission to use the facilities for experimental work at the Buckston Browne research farm; secondly, to the authorities of my own medical school, in the University of Durham, for their constant encouragement and support; and finally to my friend Mr. Laurence O'Shaughnessy not only for his stimulating criticism but also for the generous way in which he has given me the benefit of his extensive experience in this branch of surgery.

**THE MENTAL AFTER-CARE ASSOCIATION.**—The annual report of the council of the Association, covering the year 1935, shows solid extension of work and records growing effort. Last year 3307 patients were helped, being an increase of 117 over the previous year, and while the question of employment remains one of the chief difficulties of those responsible for the conduct of the Association, 200 situations were found last year. The balance sheet and financial statement show how carefully the resources must be husbanded to meet so many methods of rendering assistance, and once again the Association records its deep indebtedness to the chairman, Lord Wakefield of Hythe, for large and repeated generosity.

## THE EFFECT OF OESTRIN ON THE PITUITARY GLAND

BY W. CRAMER, Ph.D. Berlin, D.Sc. Edin.,  
M.R.C.S. Eng.

AND

E. S. HORNING, D.Sc.

BEIT MEMORIAL RESEARCH FELLOW

(From the Imperial Cancer Research Fund, London)

(WITH ILLUSTRATIONS ON PLATE)

In a recent paper<sup>1</sup> we recorded the fact that the prolonged application of oestrin produces adenomata of the anterior lobe of the pituitary gland, which are of the chromophobe type. The appearance of pituitary adenomata after oestrin, without any indication of their histological type, has since been confirmed by other workers (McEuen, Selye, and Collip<sup>2</sup>; B. Zondek<sup>3</sup>). In our paper we also referred briefly to the more general effects of the prolonged application of oestrin affecting the whole endocrine system and creating a condition of hypopituitarism including cachexia. The pituitary is always enlarged, the adenomatous change being only an extreme and exceptional manifestation of this hyperplasia. Enlargement of the pituitary after oestrin has been recorded by several observers (Korenchevsky and Dennison<sup>4</sup>; Selye, Collip, and Thomson<sup>5</sup>; B. Zondek<sup>6</sup>; Halpern and D'Amour<sup>7</sup>). But the enlargement of an organ tells us nothing about its functional activity. A priori, one would expect hyperplasia of a gland to produce the general effects of an excessive rather than a diminished functional activity. The fact that the hyperplasia of the pituitary produced by oestrin is associated with conditions in other organs resembling those produced by complete removal of the pituitary appears paradoxical and requires an explanation, which is the object of this communication.

It is well known from Cushing's clinical observations on man that pituitary adenomata produce very different effects according to the type of cell—chromophobe or chromophil—of which they are composed, the chromophobe adenomata being associated with the general condition of hypopituitarism. The fact that, as stated in our previous paper, the adenomata produced by oestrin are of the chromophobe type explains, therefore, the condition of hypopituitarism observed in those animals with pituitary adenoma. We have now been able to establish by histological examination of an extensive material, differentially stained to show the three types of cells in the anterior lobe, that a corresponding cellular change is produced by oestrin in the anterior lobe of the pituitary even when no adenoma is produced and the gland is merely enlarged; there is then an extensive diminution and sometimes an almost complete disappearance of the chromophil cells—both basophil and acidophil—of the anterior lobe, which is the part of the gland undergoing hyperplasia (see Figures on Plate). In addition, there is always a congestion of the anterior lobe, which is so intense that it is noticeable with the naked eye and that it sometimes leads to hæmorrhages of varying degree. Frequently colloid is found lying between the cells of the anterior lobe, sometimes in considerable masses. Occasionally we have seen indications of colloid degeneration in the cells of the pars intermedia.

Since the chromophil cells are generally held to be responsible for the formation and secretion of the specific hormones of the anterior lobe, their disappearance after the prolonged administration of œstrin offers a satisfactory explanation of the development of a condition of hypopituitarism which comprises together with a general condition of cachexia, the degenerative changes in the adrenals and in the gonadal organs, the extensive hyperplasia of the islets of Langerhans, and the atrophy of the thymus already referred to in our previous paper, also changes in the thyroid and parathyroid, which require further study.

In our experiments with mice males and females were about equally affected by œstrin. In both, there is an enlargement of the anterior lobe and an extensive diminution of the chromophil cells together with the general changes in the organism. Zondek's experience<sup>6</sup> that females do not respond to œstrin by enlargement of the anterior lobe is exceptional. Two other groups of workers (McEuen, Selye, and Collip<sup>4</sup>; Halpern and D'Amour<sup>2</sup>) using rats, as Zondek did, record an enlargement of the pituitary in females as well as in males. In any case this is a point of minor importance. For Zondek's observations agree with ours in finding that œstrin produces an arrest of growth and atrophy of the genitals in females as well as in males. The appearance of adenomata of the anterior lobe is also not confined to one sex. We found adenomata in two male mice and in one castrated male, Zondek observed one adenoma in a female rat, Collip and his colleagues in three castrated female rats. If there is a difference between the two sexes in their reaction to œstrin it can only be one of degree, and the difficulty is to select among the extensive changes produced by œstrin the one that represents the most direct and fundamental effect and that could give measurable data, which could be analysed statistically. At present our impression is that castration renders the animals of both sexes more sensitive to the action of œstrin.

#### SUMMARY

The prolonged application of œstrin results functionally in a condition closely resembling that following hypophysectomy. Morphologically it produces a hyperplasia of the anterior lobe of the pituitary, in which, however, the chromophil cells are greatly diminished, so that the enlarged anterior lobe consists mainly of chromophobe cells. There is also an intense congestion which may lead to hæmorrhages in the anterior lobe together with an excessive production of colloid which sometimes permeates the anterior lobe. On the assumption that the chromophil cells are responsible for the production of the specific hormones of the anterior lobe, the general condition of hypopituitarism and the extensive changes in the other endocrine organs produced by œstrin find their explanation in this disappearance of the chromophil cells of the anterior lobe.

## CONGENITAL DISLOCATION OF THE HIP

ITS PREVENTION AND TREATMENT WITH ABDUCTION BRACES

By Dr. FELIX BAUER

ORTHOPÆDIC SURGEON, REICHSANSTALT FÜR MÜTTER- UND SÄUGLINGSFÜRSORGE, VIENNA

(WITH ILLUSTRATIONS ON PLATE)

The cause of congenital dislocation of the hip is under-development of the joint. In a shallow acetabulum with a poor roof, the head of the femur is not held firmly enough and in due course it comes out, usually in the first months of life. Hitherto the usual non-operative treatment has been to reduce the dislocation—usually a long time after it occurs—and then to fix the joint for several months; shrinking and contraction of the soft parts keep the head of the femur in place. There is no growth of the joint during the period of fixation: it is not until several months later that very slow development begins, when the joint is used again; and only in a minority of cases does this lead to an approximately normal anatomical structure. This fact is very important, for when the patient treated is examined ten or twenty years after reduction it is very often apparent that the anatomically imperfect joint cannot be much used on account of arthritis and subluxation, even if its function was good immediately after treatment, when cure seemed complete.

My study of the causes of congenital dislocation of the hip has shown that the joint needs, even more than a good inherited constitution, function with plenty of movement and the abduction natural in the fetus. If the intrauterine posture is very cramped, the limitation of movement and the adduction of the joint hinder its development. My new method of treatment rests on these facts, as well as on prophylaxis and early diagnosis of deformities—dislocation, subluxation, and the flat acetabulum. From the very beginning treatment is directed not only against the mechanical error in the joint, the dislocation, but also against the under-development which predisposes the joint to dislocation and later to arthritis and subluxation. The latter may occur in cases in which there was no dislocation at an early age. Treatment must therefore offer the backward joint both function and abduction. Fixation, which until now has played the chief part in conservative (non-operative) treatment I repudiate as injurious; it hinders the growth of the joint, and makes it extremely atrophic in all its elements. It is also necessary that treatment should begin as soon as possible after birth, for the joint should remain empty for the shortest time. My aim is to cure as early as possible not only mechanically, but also anatomically. Treatment by my "abduction braces," which leave the joint mobile, has now been tried on 27 cases—21 in the first year and 6 in the second year. Up to the present, with the fixation method, the joint after reduction has been held in place in an unnatural manner by shrinking and contracture of the atrophic soft parts, leaving the acetabulum poor and unchanged. With my treatment this is achieved by the strengthened soft parts and by improvement in the joint in its most important part, the roof of the acetabulum. This begins at once and can always be seen in the skiagram as early as 4–6 weeks after reduction.

## METHOD OF TREATMENT

The first step in my treatment is reduction as early as possible; this is perfectly harmless for the infant when done by a practised hand, and never needs an anæsthetic. Immediately after the reduction the abduction braces are applied. These consist of cotton webbing so arranged as to draw the knees apart by attaching them to a band round the lower thorax (Figs. I. and II.). Natural mobility is

FIG. I.—The braces from the front.

unhindered, only adduction and extension of the hip being prevented, to an extent varying with the state of the joint. The braces cause mother and child no trouble and do not hamper care of the infant in the least. The child can lead a natural, happy life with much movement, and develops very good musculature, especially around the hip-joint. The child must be able to kick and to lie on his abdomen a good deal, and to crawl as soon as possible. The treatment is not to be disturbed even by severe illness. A twin whose dislocation was reduced at 2 months became dangerously ill with pneumonia, but in the children's hospital the abduction braces were left on all the time, as they were no hindrance to nursing.

This proves that there is no lower age limit for this treatment and that it can be carried out easily, even with the youngest infants and under difficult conditions. Two other children had severe phthisis in the first and second year of life, and the treatment was continued uninterrupted. Admission to hospital has never been necessary; children living outside the city can be taken home immediately after the reduction and put in charge of their own doctors. The braces can be changed easily by the mother herself. The younger the child, the simpler and more natural is the course of treatment, as it gives the infant a position natural to him from the foetal period. During the second half of the first year, when the child's desire to move increases and he begins to sit up, a light stick between the knees is added to the braces, which only prevent adduction and extension, and leave plenty of freedom for other movements of the joint except extension. It allows crawling, and, later, standing and walking with the legs spread apart. As a rule, the treatment lasted 7-8 months in the first year; if it is begun in the second month, as I require, an anatomically normal joint is usually obtained during the first year. But even at the beginning of the second year I have succeeded in treatment without fixation. Abduction braces and stick were always quite enough to ensure reduction with the best position of the femoral head in the joint. These children also lead a happy life, full of movement, in the braces. They crawl about a fortnight after the reduction, and according to the condition of the joint, they may soon stand and walk. The development of the joint is at this time, also, decidedly better than with fixation, and it begins in the second month after reduction.

At the time when the child would otherwise be taken out of the plaster-of-Paris cast with an undeveloped, atrophic joint and poor musculature, and would be taught to walk with great difficulty and enormous care, I have after my treatment a

child who can walk normally, with excellent hip muscles developed by exercise in the abducted position, and, most important of all, as the X ray pictures show, with a normal, or at least much improved, joint with a deep acetabulum and a good roof, which continues to develop rapidly (Figs. III. and IV. on Plate). The outlook for such a joint is certainly much better than the outlook for the undeveloped, atrophic joint left by the fixation method.

## EARLY RECOGNITION

The earlier the better, without qualification, is my principle for beginning treatment. It may start in the first weeks of life, and it is easier and more natural to carry out while the infant is still recumbent. The latest time is as soon as possible after dislocation, but it is far better to avoid dislocation by beginning at an earlier stage. Practitioners, especially those concerned with infant welfare, should diagnose the congenital subluxation and dislocation at the earliest possible moment. This is easy, as I have shown that the cramped posture of the foetus in the uterus is the usual and most important cause of the under-developed joint, and that it persists in the infant, after a short period of disturbance at birth (lasting 2 or 3 weeks) and is almost always easy to recognise, because as a rule it is associated with asymmetry. Such an infant is compelled to lie on one side and usually its skull is noticeably asymmetrical. The cramping causes contractures and limitation of movement in the hip, usually much more marked on one side than on the other. On the soft parts of the inner side of the thigh the forced position of the limb causes a different formation of the folds on the two sides, and finally, in the joint, the delay in ossification and in the growth of the acetabulum is usually greater on one side than on the other.

To diagnose in an infant an undeveloped joint due to its cramped posture in the foetus attention should be paid therefore to the following points:—

- (1) Does the child lie on one side only? Does the pelvis take part in this? Is there asymmetry of the skull?
- (2) Do the folds of the inner side of the thigh differ in depth, number, or position?
- (3) When lying on the back as symmetrically as possible, is there a difference in the position of the hip-joints? Is one adducted, bent, or externally rotated more than the other? Or are both much adducted or rotated?
- (4) Is one leg moved less than the other?
- (5) Does one leg appear shorter?
- (6) When an attempt is made to spread the legs apart, is there a stronger resistance on one side than on the other, or is it very strong on both sides?

The positive findings must be completed by X ray

FIG. II.—The braces in use.

photography of the joint and consultation with a specialist. In such an examination as this the hip which is above as the child lies on the side it prefers is always the poorer, with the flatter acetabulum and retarded development of the centre of ossification in the head of the femur; it shows more severe contractures, chiefly in abduction, often is decidedly sparse in movements, and as a rule there are numerous long folds in the skin of the upper part of the thigh; this leg also often appears shorter. Every infant should be examined by the doctor for these signs from the fourth week. The symptoms of the dislocation itself—real shortening of the leg, broadening of the flanks, flattening of the nates, inward and downward displacement of the axis of the thigh, prominence of the great trochanter, and other asymmetries of the body—are discernible in only a few infants, because of the slight degree of dislocation at this age, and they hardly come under consideration for diagnosis at the general examination. Even the specialist will be able to distinguish between subluxation and dislocation only in a minority of the cases. On the other hand, the X ray picture gives the experienced person reliable information; apart from this, in almost all cases the clicking sign can be elicited during reduction, when the femur head is introduced into the acetabulum.

With my methods of examination, not only congenital dislocation itself (with an incidence of about 3 in 1000) but also a much larger group of high-grade undeveloped joints due to foetal cramping (3 in 100) can be recognised. We may expect a dislocation in about every 8th female infant and every 50th male infant with the signs of a high degree of cramping. At any rate, the large majority (possibly all) of the dislocations are caused by this foetal position, and heredity is of much less importance. There is no doubt that some degree of under-development, as shown by these tests, is within physiological limits; others are destined for arthritis and other joint changes. It is necessary to recognise this larger group in order to treat the hip in the stage before dislocation, because contraction and poor movement make the joint worse during the first year of life, just as they do in the foetus, and must therefore be relieved. This is done in any case by reduction and exercise, in higher degrees, exactly as in complete dislocation, with functional treatment by the abduction braces. In 36 higher-grade subluxations, a good anatomical result was usually achieved in 3 to 6 months by reduction and the spreading band.

#### CONCLUSIONS

The natural functional treatment of congenital dislocation of the hip is carried out with abduction braces, according to the following principles: (1) Treatment begins as early as possible. (2) Function is as natural as possible, and the legs are spread as far as is necessary. (3) The injurious fixation hitherto used is avoided. (4) The necessary early diagnosis is made in the 4-8th week by recognising the effects of the foetal posture. (5) The result of the treatment in all cases is rapid mechanical cure without danger of recurrence, owing to the natural development of the joint and its soft parts. (6) When the treatment begins at the right time, good development of the joint always begins immediately after reduction and anatomical cure is achieved usually in a short time. (7) The treatment does not give rise to any complaints and has shown consistently good results when applied during the first and second years of life.

## THE CAUSE OF HYPERTENSION IN PRE-ECLAMPTIC TOXÆMIA

### A STUDY OF BLOOD PRESSURE IN MOTHER AND INFANT

BY F. J. BROWNE, M.D. Aberd., D.Sc. Edin.

DIRECTOR OF THE OBSTETRIC UNIT, UNIVERSITY COLLEGE HOSPITAL; PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF LONDON; AND

GLADYS H. DODDS, M.D., M.C.O.G., D.P.H. Edin.

ASSISTANT IN THE OBSTETRIC UNIT

RECENT researches have tended to show, but so far without bringing forward convincing evidence, that the cause of the hypertension that is the earliest and the most constant of the three cardinal signs of pre-eclamptic toxæmia is likely to be found in the presence in the patient's circulation of a blood-pressure-raising substance, derived from a gland of internal secretion—perhaps the pituitary or the adrenal. An alternative and older hypothesis is that the pressor substance is derived from the placenta, possibly from degenerative changes therein. In either case it is to be presumed that the substance is soluble in the mother's blood, and being so, might pass freely via the placenta and cord into the foetal circulation, where it would lead as in the mother to a rise of blood pressure, which should be demonstrable in the child immediately after birth. We therefore decided some three years ago to study the blood pressure of the infants of hypertensive mothers, and this we have done in several cases. Most of the infants were born by Cæsarean section and in every case the blood pressure of the mother was at a very high level just before the section was performed. The pressure was measured in both mother and child by the same instrument—a baumanometer using the auditory method. In the infants a specially small armet had, of course, to be employed.

In none of our cases have we been able to demonstrate a rise of blood pressure.

#### ILLUSTRATIVE CASES

The following are three typical examples.

CASE 1 (A.638).—Aged 38. History of one miscarriage at three months in January, 1934. No other pregnancy. In the present pregnancy she was sent in as an emergency case by an outside doctor on account of pre-eclamptic toxæmia which was said to have been present for a month. On admission on May 8th, 1935, the B.P. was 198 systolic, 120 diastolic; there was oedema of the legs as high as the knees and also of the face; there was headache of two days' duration and epigastric pain had been present for some hours. Albumin was so much that the urine was too solid for Esbach estimation; hyaline casts alone were present and a few red blood-cells. Blood-urea, 29 mg. per 100 c.cm.; urea concentration, 2.35; urea-clearance, 49 per cent. Routine expectant treatment was carried out for seven days but the condition improved but little, the B.P. varying between 210 and 150 systolic and between 130 and 90 diastolic. Though the epigastric pain disappeared on the day after admission and did not return, severe pain was complained of in the back of the neck on May 12th, on which date the B.P. was 200 systolic, 130 diastolic. The pain continued till delivery. Cæsarean section was done on May 16th, the patient being then about three weeks short of full term. A premature child was delivered which weighed 5 lb. 2½ oz. and was 18 inches long. Three hours before operation the mother's blood pressure was 200 systolic, 150 diastolic. Half an hour after its birth the infant's blood pressure was 80 systolic. Daily readings were taken till June 6th. During this time the infant's systolic B.P. varied from 92 to 72 mm. Hg

with a mean of 80. On discharge from hospital on June 6th the mother's B.P. was 143 systolic, 80 diastolic; there was still a trace of albumin, but no casts, and no visible œdema. When she was seen six weeks after delivery the B.P. was 144 systolic, 102 diastolic, and the urine contained albumin.

*Comment.*—This was probably a case of pre-eclamptic toxæmia.

CASE 2 (A.332).—Aged 31. One previous pregnancy which ended in eclampsia for which she was admitted as an emergency in 1931. A macerated foetus was born. In the present pregnancy she was first seen on Sept. 12th, 1934, at the eleventh week of her pregnancy. Her B.P. was 176 systolic, 100 diastolic. Except for a short period in hospital for renal efficiency tests she was treated as an out-patient till Feb. 10th when she was admitted to hospital. Blood pressure then was 190 systolic, 100 diastolic, there was a trace of albumin, and some œdema of the legs and abdominal wall, but no abnormal symptoms. Blood-urea, 32 mg. per 100 c.cm.; urea concentration, 2.6; urea-clearance, 64. The blood pressure remained high after admission, the systolic varying between 220 and 152 and the systolic from 110 to 80. Cæsarean section was done on March 3rd at 2.30 P.M. The mother's B.P. at 10.30 A.M. on that day was 220 systolic, 100 diastolic, and at 12.30 the systolic and diastolic pressures were 210 and 100 respectively. The infant was at term and weighed 8 lb. 2 oz. at birth. At 6 P.M.—i.e., 3½ hours after birth—its systolic B.P. was 70 mm. Hg. Daily readings till March 24th showed that the systolic B.P. varied between 84 and 64, the mean being 76. The diastolic pressure on the four occasions on which it was recorded varied from 50 to 40. The patient was seen on March 4th, 1936, when her B.P. was 162 systolic, 90 diastolic. She has a trace of albumin that comes and goes.

*Comment.*—This patient probably had a mild chronic nephritis and hypertension dating from the first pregnancy. It is noteworthy that at the eleventh week of the present pregnancy the B.P. was considerably raised, and that the hypertension still persists a year after delivery.

CASE 3 (A.339).—Para-5, aged 38; is said to have suffered from "kidney trouble" in each of her five previous pregnancies, but has three children alive and well, all being apparently born somewhat prematurely. In her first pregnancy she had been in City-road Maternity Hospital for three weeks before delivery for "kidney trouble." In 1924 had a stillborn child at term. First came under our observation in 1930 when she had pre-eclamptic toxæmia; the hypertension persisted after delivery, and four months after delivery the B.P. was 220 systolic and 110 diastolic. In the present pregnancy she was first seen on Nov. 19th, 1934, when 22 weeks' pregnant. The blood pressure was then 200 systolic, 110 diastolic, albumin absent. She was treated as an out-patient till Feb. 19th, the blood pressure readings during all that time never being below 200 systolic and 140 diastolic. On Feb. 13th albumin was found in a catheter specimen but the patient remained free from symptoms. She was admitted to hospital on Feb. 19th and was under constant treatment there till delivery on March 18th, when after a medicinal induction followed by a precipitate labour a child weighing 4 lb. 8½ oz. and 20 inches long was born in good condition. According to the patient's menstrual dates and judging from the length of the child it was at full term. During the patient's stay in the antenatal ward the B.P. remained constantly very high, and was little or not at all influenced by rest and other routine treatment, including ultra-violet rays, which were given on alternate days throughout the period. Results of kidney function tests were as follows: blood-urea, 28; urea concentration, 2.8; urea-clearance, 122. Albumin was constantly present and on March 13th had increased to 3 per 1000. Hyaline and granular casts and a few red blood-cells were present on all the three occasions on which the urine was examined microscopically. The patient's blood pressure on discharge on March 23th was 208 systolic, 116 diastolic, and there was still a trace of albumin but no casts. In August the B.P. was still 212 and 140 systolic and diastolic respectively, and there was still a trace of albumin, but no casts nor blood. The baby's blood pressure nine hours after delivery was 76 systolic, 34 diastolic.

*Comment.*—The diagnosis here lies between chronic nephritis and chronic hypertension. Against the former are the good results of the kidney function tests. On the other hand, the appearance of albumin on Feb. 13th and its persistence and increase till term point to a super-imposed kidney lesion or to an exacerbation of one already present.

As controls we carried out estimations of the blood pressure in six normal infants at periods varying from 2 to 18 days after birth. The systolic pressure varied between 68 and 86 with a mean of 73.

#### SUMMARY AND CONCLUSIONS

The paper is concerned with a study of the blood pressure in infants born of mothers who had hypertension before delivery. It might be supposed that if the cause of the hypertension in pre-eclamptic toxæmia and other hypertensive conditions in pregnancy were a substance, hormonal or otherwise, circulating in the mother's blood, this substance would diffuse through the placenta to the foetal circulation, and that the infant would then have a raised blood pressure at birth. Three typical and representative cases are reported in detail, and it is shown that there was no rise of blood pressure in the infants. It is, therefore, concluded that whatever be the cause of the hypertension in pre-eclamptic toxæmia, it is not a substance that is capable of passing across the placenta into the foetal circulation.

### BRAIN AND LUNG ABSCESSSES AND BENIGN SPONTANEOUS PNEUMOTHORAX AS COMPLICATIONS OF OTITIS MEDIA

By P. R. ALLISON, M.B., B.Sc. Leeds, F.R.C.S. Eng.  
SENIOR SURGICAL TUTOR AND REGISTRAR, GENERAL  
INFIRMARY, LEEDS

F. F. HELLIER, M.A. Camb., M.D., M.R.C.P. Lond.  
MEDICAL TUTOR AND REGISTRAR; AND

G. S. SEED, M.B. Leeds, D.L.O.  
RESIDENT AURAL OFFICER AT THE INFIRMARY

BRAIN and lung abscesses are well-recognised complications of otitis media and lateral sinus thrombosis, but for a patient to have both of these and to regain normal health must be uncommon. The case here presented is also of considerable interest because following lung abscesses and empyema on the right side there occurred on the left side a complete spontaneous pneumothorax. Although this was not associated with any infection of, or effusion into, the pleural sac, the evidence points to its having arisen as a result of an infective process in the lung.

#### CASE REPORT

A man, aged 22, was admitted to the General Infirmary at Leeds under the care of Mr. W. M. Munby on April 29th, 1934. There was a history of left-sided otorrhœa for three months, and for six days before admission there had been pain in the ear associated with an increase in the discharge. The patient had no symptoms to suggest intracranial complications. His temperature was 98.4° F., with pulse-rate 84 and respirations 24, and he complained of slight headache. The left external auditory meatus was filled with foul-smelling discharge which was escaping from a large perforation in the posterior part of the tympanic membrane. There was a leucocytosis of 23,150, and coliform bacilli, *B. proteus*, and diphtheroid organisms were isolated from a meatal swab. An examination of the central nervous system and the fundus oculi revealed

nothing abnormal. During his first night in hospital he had a rigor. The suggested diagnosis was acute mastoiditis with lateral sinus thrombosis.

**Operation on mastoid.**—On April 30th a simple Schwartz operation was performed by Mr. Munby. Much necrosed bone and foul pus were removed from the mastoid cavity. Exposure of the lateral sinus revealed a grey sloughing wall locally, but enough bone was removed to discover normal looking sinus beyond. After incision of the sinus and removal of the clot free bleeding occurred from the torcular but not from the jugular end. In the middle cranial fossa a large extradural abscess was found and into this a fistulous track opened through the dura mater from a temporo-sphenoidal abscess. The track was opened and a drainage-tube inserted. The mastoid cavity was packed with gauze. A swab was taken from the brain abscess and culture of this showed the presence of organisms similar to those isolated from the external auditory meatus (coliform bacilli and *B. proteus*). For about ten days the fever was intermittent, the temperature occasionally rising to 105° F. but most often being between 97° and 100°. The mastoid wound and the abscess drained freely and there was no sign of further intracranial disturbance.

**Right-sided lung abscesses and empyema.**—About a fortnight after his mastoid operation the patient first complained of a pleuritic pain in the right side of his chest and a few days later he coughed up a large quantity of foul sputum. A lung abscess of embolic origin was diagnosed and it was treated by simple medical measures until June 4th by which time it had become obvious that an empyema had developed. After confirmation of this by X ray examination (Fig. 1) the chest was explored on the right side, and thick foul pus was withdrawn, which yielded *B. coli* on culture. An open operation was therefore performed. Under local anæsthesia an oblique incision was made over the eighth rib on the right side starting just internal to the scapular line and passing outwards to the axilla. About 2 in. of rib were removed, and after confirmation of the site of the pus by exploration the pleura was freely opened. When the rib spreaders were introduced and a large quantity of malodorous pus had been removed from the pleural sac, on the surface of the lung a ragged abscess cavity about 2½ in. in diameter was found. The abscess had developed from a septic infarct in the cortex of the lung and its appearance suggested that the whole outer wall of the cavity had sloughed away and liberated the pus into the pleural sac. Some large sloughs of lung tissue were removed and the empyema cavity carefully wiped out with gauze soaked in Dakin's solution. When the patient coughed there was little expansion of the lung but the presence of a bronchopleural fistula became evident. Open drainage of the pleural sac was instituted.

**Ligation of internal jugular vein.**—The post-operative progress was unsatisfactory. There was intermittent fever with occasional rigors. Since drainage was adequate and X ray examination after injection of lipiodol through the drainage-tube showed a steady diminution in the size of the empyema cavity (Fig. 2), on July 15th the latter was carefully explored under direct vision. The abscess previously described was only represented by a saucer-shaped depression on the lung surface covered with healthy granulation tissue. There were, however, two further disruptions in the lung similar to the first but somewhat smaller. On the strength of this finding it was suggested that the internal jugular vein should be ligated. This was done by Mr. Munby and thereafter progress at once became satisfactory. The temperature and pulse were normal after the operation and frequent inspection of the empyema cavity showed no further abscesses. The bronchial fistulæ were treated by cauterisation with silver nitrate stick, the lung expanded well, and the tube was left in position until the empyema cavity was completely obliterated. Some time before this end had been reached however he was sent to the convalescent home.

**Left-sided pneumothorax.**—At this time the patient's general condition was satisfactory; he was afebrile, the empyema was only small, and the drainage-tube was in position. But on August 31st he suddenly became desperately dyspnoeic with pain in the left side of the chest. One of us (F. F. H.) who was called to see him found a complete tension pneumothorax on the left side, and as an emergency measure withdrew a considerable quantity of air with a 20 c.cm. syringe and returned him to hospital. Following this attack the pulse and respirations remained high though there was no rise of temperature; the lung did not expand and yet no effusion occurred into the

FIG. 1.—Empyema on right side of chest.  
 FIG. 2.—Empyema cavity filled with lipiodol after open drainage. There is a circumscribed cavity in left subapical region.  
 FIG. 3.—Drainage-tube in position on right side and spontaneous pneumothorax on left. The adhesion on the left side is in the position of the opacity in Fig. 2.

pleural cavity (Fig. 3). The initial assumption had been that a small abscess in the left lung had ruptured, but when no effusion and no infection developed the accident was considered to be independent of the affection in the right side, and in all probability to be due to a ruptured emphysematous bulla. Subsequently, however, a more careful examination of the X ray plates which had been taken before his transfer to the convalescent home showed beyond all doubt that there was in fact a cortical opacity in the left subapical region, and that this was of recent origin was proved by inspection of some of the earlier plates (Fig. 2).

*Return to health.*—Eight weeks later radiography showed no evidence of re-expansion of the lung, and so 2000 and 3000 c.cm. of air were removed from the left side on successive days, the pressure falling from + 2 cm. to - 4 cm. of water. As this operation did not result in any expansion of the lung it was felt that there must be a small bronchopleural fistula although the patient was unable to taste peppermint injected into the pleural sac. An attempt was made to produce an effusion under which the lung might expand and become adherent to the parietal pleura. Following the advice of Dr. W. S. Gilmour, who has had success in the injection of irritant fluids into the pleural cavity where the lung has failed to expand, a solution was made up consisting of tinct. iodi 2 drachms in half a pint of distilled water, and the whole of this was injected into the left pleural sac. No reaction, either local or general, followed this treatment; there was no effusion as seen on the X ray screen, and in fact the fluid injected was rapidly absorbed, leaving the pneumothorax unchanged.

By now the patient felt very well, the empyema on the right side was healed with complete expansion of the lung, but the left lung was still collapsed and the heart displaced to the right. He was loth to undergo further treatment; but a final effort was made, and on Nov. 5th and 6th 3000 and 4000 c.cm. of air were withdrawn. This was followed by a return of the heart nearly to the normal position and expansion of the lung which rapidly became complete. The patient is now working, radiography shows two normal lungs (Fig. 4), and, except for slight deafness in the left ear, he is perfectly well.

#### COMMENT

At first this patient was believed to be suffering from an acute mastoiditis with lateral sinus thrombosis, and the presence of a brain abscess was unsuspected. There can be no doubt that this was the focus from which infected emboli were detached into the pulmonary circulation. It is interesting that the first indisputable indications of a lung abscess occurred a fortnight after operation, for this is also the typical time-interval for the manifestations of an inhalation abscess.

The effect on the temperature of removal between ligatures of the internal jugular vein was dramatic, and it seems probable that an earlier ligation might have prevented the chest complications. Consideration of the lung abscess and empyema emphasises the advantage of an adequate exposure of the pleural cavity at operation, particularly from the point of view of accurate diagnosis. A careful examination of the lung surface through a generous intercostal incision after resection of 2 in. of rib furnishes information which is invaluable in the subsequent treatment of the case. This procedure is not associated with undue danger to the patient so long as the operation is delayed until such time as repeated aspiration has relieved the immediate toxæmia and respiratory embarrassment. The prognosis in pleural infections secondary to lung abscess is not nearly so grave as is frequently supposed. The majority of such cases recover after simple drainage of the empyema, and when the lung expands the abscess is usually found to have healed completely. A bronchial fistula is not often a source of much difficulty and

where these can be attacked directly with the silver nitrate stick rapid healing is the rule.

The spontaneous pneumothorax on the left side raises some difficult problems. It was followed by no constitutional symptoms whatever apart from breathlessness, and it resembled in every way the so-called benign spontaneous pneumothorax. The cause of this condition is supposed to be a sub-pleural bulla with a valve-like orifice so that it gradually increases in size until it ruptures. Occasionally cases of this nature have been demonstrated pathologically, but the condition is comparatively common, and ten cases have been admitted to this hospital in the last three years. There is no proof that the cause is always the same. In this instance it is difficult to avoid the conclusion that the pneumothorax was due to an inflammatory lesion in the left lung similar to that which had existed in the right lung, and yet the pleura remained free from infection. It demonstrates therefore the very important fact that it is possible to have a benign spontaneous pneumothorax—i.e., one without any constitutional upset, without infection of the pleural cavity, and non-tuberculous—secondary to a pyæmic lesion in the lung. Moreover, since the pneumothorax occurred six weeks after the internal jugular vein had been tied it is possible to say that it was caused by a lesion in the lung which had been in existence at least six weeks. Whether this ætiology is of wider application in benign spontaneous pneumothorax is uncertain, but it is sufficient to suggest that the commonly accepted cause should be subjected to careful scrutiny and particular inquiry made for any hint of a more or less recent lung infection. It is important to note that by the time the lung had re-expanded there was no evidence on the X ray plate of the original causative factor.

#### THE DENTAL PROP

BY WILLIAM W. MUSHIN, M.B. Lond.

HON. ANÆSTHETIST TO THE CENTRAL LONDON THROAT HOSPITAL  
AND TO THE DREADNOUGHT HOSPITAL, GREENWICH; HOUSE  
ANÆSTHETIST AT THE ROYAL DENTAL HOSPITAL

THE dental prop, to function correctly, must be fashioned in accordance with sound mechanical principles. A search of English medical and dental literature has failed to reveal any attempt at a historical, scientific, or mechanical survey of the dental prop, although its near relative, the mouth gag, has received this attention.<sup>1</sup> Indeed I have found only two references to the prop and its use.<sup>2,3</sup>

The first mouth props were of vulcanite or hard wood, some being covered with rubber pads and others having removable handles for introduction. Clover brought out the first spring-action prop to prevent displacement in the mouth. Hewitt about 1889 designed a set of steel props; these were made in five sizes and shaped so that they adapted themselves to the angle made by the lower jaw as it recedes from the upper jaw; they are now made of aluminium or German silver. Barth in 1908 adapted these props for children and for small mouths, these models being some of the most useful props at the present time.

The ideal prop should be of robust construction and not likely to break under the strain of the bite, especially with nitrous oxide anæsthesia. It should be comfortable, simple to insert in the conscious patient, easily cleaned and sterilised, and it should

not collect blood-clot and debris on its surfaces. Lastly and most important, when once inserted it should show no tendency to slip, even in edentulous mouths.

THE ORDINARY PROP

The props now in common use are of three main types. First, there are the variations of Hewitt's original pattern, which consist of two plates or biting surfaces, lead or rubber lined, separated by a rod; they are all alike in that one of the biting-plates is set at an angle of 90° to the rod (Fig. 1). Secondly, there are the "spring" and adjustable props such as Hutchinson's and Wingrave's. Nearly all of this type were designed to fit on to the incisor teeth and to be adjustable for different widths of separation of the jaws. They suffer from the drawbacks that they are uncomfortable, liable to break in use—pieces of spring and mechanism being lost in the mouth and pharynx—difficult to sterilise and they may damage the front teeth.

FIG. 1.

Thirdly, there are the solid rubber props and wedges, such as the De Pass prop. These, although quite efficient, are clumsy in use and are of value chiefly in the unconscious patient; they have also a tendency to slip forwards towards the front of the mouth, leaving less room for the surgeon to carry out his manipulations.

No attempt will be made to describe the correct clinical use of the prop, as this has been admirably done by Mr. Frank Coleman.<sup>2</sup>

It is common knowledge that props of the Hewitt type tend to slip, especially when there are no teeth to provide a grip, and it has been observed that they always slip in the same way. Fig. 2 shows how this happens.

Let AB and BC be the upper and lower jaws respectively acting from a hinge at A. Let XY represent a prop as now in common use, with the angle AXY = 90°. Now when the two jaws bite on the prop, the forces exerted by the jaws act at right angles to the line of the jaws, since the latter are rotating round A; the force acting from the upper jaw is F and that from the lower jaw is F<sub>1</sub>, and these are equal (law of action and reaction). The prop being at right angles to AB has the full force F acting along XY from the upper jaw. But the force acting along YX

FIG. 2.—In this and the following figure the angle of opening of the jaws has been exaggerated.

from the lower jaw is only P<sub>1</sub>—a component part of F<sub>1</sub>, since F<sub>1</sub> is resolved into P<sub>1</sub> and P<sub>2</sub> acting along AC towards C (parallelogram of forces). Thus F is greater than P<sub>1</sub> and the end of the prop Y tends to slip in the direction of C. Further, as soon as the end Y moves towards C the angle AXY immediately becomes more than a right angle and by the force exerted by the upper jaw, X moves towards A, increasing still further the rotation of the prop.

The following observations have been made, which confirm the above reasoning and conclusions. If lead-lined props which have been in use for some time be examined, it will be found that wear and sometimes even bending takes place at the point R (Fig. 1)—i.e., at the proximal end of the angled

plate. This is the spot where only the grip of the teeth on the lead prevents the rotational movement of the prop already described.

A NEW PROP

In order to have a stable and non-slipping prop, the forces acting along the prop should be equal and opposite. This is shown in Fig. 3.

If the prop XY is placed so that <AXY = <AYX, then the components P and P<sub>1</sub> of the forces F and F<sub>1</sub> are equal and opposite, and the prop has no tendency for its ends to slip. The prop as a whole may now slip in the direction Z, owing to the residual component forces (F-P and F<sub>1</sub>-P<sub>1</sub>), and this will be prevented by the frictional forces between the end X and AB and Y and AC.

A prop was therefore designed embodying these principles and differing radically from previous props of the Hewitt type, in that the two biting-plates are set at equal angles to the central rod (Fig. 4). The two plates have been made to subtend an angle of 20°, which was found to be an average degree of

FIG. 4.—The improved prop; it is made of chromium-plated German silver.

opening after observation and measurement of a large number of cases of tooth extraction. The biting-plates have fairly hard pieces of rubber with a moderately fine canvas impression, inserted in the manner of the well-known Trewby prop. This was found to be the best after experimenting with several frictional surfaces. It does not get soiled, it can be sterilised repeatedly, and although not so important as the biting-plate angles, helps considerably in preventing slipping. The biting-plates are slightly curved in a transverse direction for added comfort and stability. The canvas-impressed rubber is so fixed that it cannot fall out, and when worn out it can be renewed in a moment at negligible cost.

The prop therefore complies with the theoretical mechanical requirements for stability, in that the biting-plates are set at equal angles to the central rod, and an attempt is made to increase the frictional forces between the plates and the gums. To further this, it is recommended

FIG. 3.

that the patient should thoroughly rinse his mouth with water immediately before inserting the prop. This will reduce the viscosity of the saliva between the prop surface and the gum, and will help still further to prevent the prop slipping.

This prop has been in use for some time in the general anaesthetic room of the Royal Dental Hospital; no tendency to slip was found in the several hundred edentulous patients on whom it was tried. The largest size possible for any particular mouth should be used, for if a smaller one is inserted the patient may involuntarily open his mouth a little during anaesthesia and cause the prop to slip or fall out. The prop was originally intended for edentulous

mouths, but for those who prefer to use lead it may be substituted for the rubber surfaces in patients with teeth.

I wish to thank Mr. Frank Coleman and the staff of the Royal Dental Hospital for their encouragement and help, and the Dental Manufacturing Company who made the props for me.

## Clinical and Laboratory Notes

### UNSUSPECTED PLACENTA PRÆVIA AND POST-PARTUM HÆMORRHAGE

BY DOUGLAS M. LINDSAY, M.D., F.R.F.P.S. Glasg.

LATE OBSTETRIC AND GYNÆCOLOGICAL SURGEON, MAYDAY HOSPITAL, CROYDON; AND SENIOR ASSISTANT VISITING SURGEON, ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW

WHEN one meets post-partum hæmorrhage in its most severe and sudden variety the experience is one which leaves a lasting impression. Recently it was my misfortune to have such a case, and on the score of its unusual pathology and because only one line of treatment—and that an infrequently practised one—was applicable, it deserves record and consideration.

## CASE RECORD

The patient, a primipara aged 26, was first visited when she was six months' pregnant. Apart from some pruritus due to a congestive leucorrhœa she felt well, and examination showed her to be a woman in good health; obstetrically the findings were normal.

At eight months the patient reported to the nursing-home thinking that labour had commenced. She had some backache, and after a night in the home there was a slight mucohæmorrhagic "show" on a diaper. A colleague, acting in my absence, kept her under observation for two days, and then sent her home as things seemed to have settled. From the time of her return home till the day on which labour was anticipated there was nothing to suggest anything unusual.

Labour began at 8 P.M., the first warning being the rupture of the membranes. Readmitted to the home, the patient experienced her first pains about 10 P.M. From the onset till the child was born uterine contractions were severe, long, and following fast one on another. The progress was so rapid that by 12.30 A.M. the head was crowned, and sufficient chloroform to produce analgesia was administered. Delivery was completed normally at 12.40 A.M., without perineal injury and with the child breathing and crying immediately. Until the cord was clamped and cut there had been not so much as a staining of blood throughout the whole process.

I stood by the patient with a hand gently supporting the fundus, waiting for the next contraction or any sign of the beginning of placental separation. After a few minutes the fundus hardened suddenly, and immediately the placenta and its membranes were expelled forcibly. As the placenta left the vagina there came the most alarming hæmorrhage, exceeding in suddenness and amount anything I had previously known. It arrived with the splashing and volume of a bucket of water sluiced on a floor, and in a matter of two or three seconds my patient had changed from a healthy coloured, softly breathing, fit young woman to a waxy pallid creature, gasping, restless, and seriously distressed.

The uterus seemed to have retracted as well as contracted in its last expulsive effort, as it rested "cricket-ball hard" under my hand. It was so firm that assuredly it was not at fault, while the fact that there had been no bleeding from the onset of labour right up to the time

of the placental escape ruled out cervical or vaginal lacerations, which, short of involving a very large vessel, could not possibly have accounted for the volume so suddenly lost. The only source could be the lower uterine segment.

I introduced the right hand into the vagina and clasped the lax cervix, gripping it tightly in a clenched fist and pressing upwards while the external hand pressed downwards producing through the hard fundus a rigid bimanual compression. Though only seconds had elapsed between the first sign of the flooding and this control being applied, the patient was already in extremis. The step taken immediately controlled the loss. Realising that a further bleeding, even of a few ounces, would prove fatal, I determined to maintain the pressure until I felt reasonably confident that the bruising and stasis I had produced had made clotting in the open sinuses fairly certain. I waited therefore for a full half-hour and then gradually released the pressure, removing the vaginal hand only when satisfied that the bleeding had ceased.

While I had been thus occupied the theatre staff had elevated the foot of the bed, applied hot bottles and an electric blanket, and commenced the administration of submammary saline. Only after these matters were attended to, and I had controlled the loss, was a stimulant given, the choice being camphor in oil.

Later, examination of the placenta made the cause of the hæmorrhage clear. The placenta was larger than usual, and one half was much thinner than the other. The opening in the sac of membranes was situated at the edge of the thinner portion of the placenta, and placental tissue formed quite half the edge of the perforation in the membranes. Over the thin area of placenta the maternal surface was covered with a layer of highly organised blood-clot. The pathology became apparent: this had been a case of placenta prævia, and the very free sudden hæmorrhage after placental expulsion had been from the sinuses of the flaccid non-contractile lower uterine segment.

## DISCUSSION

When, as is usual, placenta prævia lives up to its name as an unavoidable ante-partum hæmorrhage the attendant is forewarned, and steps are taken to control the further bleeding which is expected when the placenta separates. For years my practice, and I have found it a sound one, has been to remove the placenta manually and apply the bimanual compression described above in all births attended by placenta prævia. Here, however, the abnormality in placental implantation was discovered only after labour, and the hæmorrhage was unfortunately fait accompli before one realised the position.

In retrospect there are two points of moment—the mucohæmorrhagic "show" at eight months, and the fact that labour started abnormally in the rupture of the membranes. Viewed in the knowledge of the pathology of the bleeding, that "show" was important, but in the absence of other pointers this was not appreciated. Had it been larger, or repeated, one would have become suspicious; though the fact that the pregnancy carried on to the very day on which delivery was anticipated, and that the labour was completed without even a staining, would probably have put any such fears at rest. Nature asserted herself to save this patient from blood loss. The membranes ruptured early, the head was well down in the lower uterine segment, and the labour was strong, long, and unrelenting. As the cervix dilated and the placenta was peeled from its attachment in the lower uterine segment, the strong contractions kept the head braced firmly into the cervical canal and pressed the placenta against the gaping sinuses, controlling the loss like a swab held firmly over a cut surface. To a point Nature did her job well—one is tempted to speculate if she may not do this particular job oftener that we suspect

and with better results—but she failed in her last difficulty. When the placenta came away the all-important sinuses were reopened and the flood released.

From the clinical viewpoint this type of unsuspected placenta prævia is important, as the only way of controlling the post-partum hæmorrhage associated with it is the practice of bimanual compression. The bleeding from a lower uterine segment is controlled primarily by clotting. The administration of pituitary preparations or ergot, or resource to stimulants likely to raise blood pressure are not only useless but dangerous. Hot intra-uterine douches, that old reliable favourite never at hand when most required, are not permissible, for they remove clots already formed and produce fresh loss. For once possible infection must become a secondary consideration. Bimanual compression must be applied immediately as the urgency cannot be greater. Once the hand is introduced it should be kept in the vagina. Insertion, removal, and reintroduction later simply increase the chance of sepsis. Do not rush to stimulants or blood transfusion. Counteract shock with posture and warmth, and replace fluid loss with salines. If additional blood is required it will the better fulfil its function if transferred when the initial shock is over and the patient better fit to face the ordeal.

Often it will be found after a few hours that an astonishing recovery has taken place. This happened in the case I have reported here, and a complete recovery was rapidly made on liver extract, iron and arsenic, generous diet, and good nursing. As can happen, the temperature never rose above the normal in spite of my interference and the grave blood loss. This was contrary to all the rules of the game, but perhaps I should have anticipated this, for the patient did not seem to pay due respect to those rules from the beginning.

### GASTRO-JEJUNO-COLIC FISTULA WITH TERMINAL PERFORATION INTO THE PERITONEAL CAVITY

By H. SEAWARD MORLEY, M.D., M.R.C.P. Lond.

PHYSICIAN TO THE ROYAL WEST SUSSEX HOSPITAL, CHICHESTER;  
CLINICAL ASSISTANT AT UNIVERSITY COLLEGE HOSPITAL,  
LONDON

*With a Note on the Surgical Aspect by*

R. BROOKE, Ph.D., M.S. Lond., F.R.C.S. Eng.

SURGEON TO THE ROYAL WEST SUSSEX HOSPITAL, CHICHESTER

*and on the Pathology by*

C. J. HARWOOD LITTLE, O.B.E., M.B. Leeds

PATHOLOGIST TO THE HOSPITAL

LAST October Drs. Mindline and Rosenheim described in THE LANCET<sup>1</sup> a case of duodenocolic fistula simulating idiopathic steatorrhœa. At that time I had in one of my beds at the Royal West Sussex Hospital a very similar case in which steatorrhœa was also present; and as there were additional points of interest, it seems worth recording. Incidentally it is strongly reminiscent of a case<sup>2</sup> under the care of Dr. F. J. Poynton in University College Hospital in 1930, which I saw as medical registrar.

#### CLINICAL RECORD

The patient was a man, aged 41, a bus conductor, admitted on Sept. 11th, 1935, and referred by Dr. Francis

Leslie of Chichester. He complained of intermittent pain in the umbilical region for the previous six weeks; vomiting about a quarter of an hour after meals, which relieved the pain; and, frequently, a loose action of the bowels soon after a meal "as if the food ran through him." For the same period he had noticed an increasing distension of the abdomen and swelling of the legs, the latter subsiding with recumbency.

*Previous history.*—The man had been first admitted to the Royal West Sussex Hospital under Mr. R. Brooke on August 28th, 1927, complaining of severe pain in the epigastrium a quarter of an hour after meals, relieved by vomiting. Radiography showed a small irritable stomach emptying in four hours with some tenderness over the pyloro-duodenal area. A test-meal showed a marked hyperchlorhydria. The presence of a duodenal ulcer was diagnosed, and as the history was short, the patient young, the stomach rapidly emptying, and the stomach contents very highly acid, the case was thought to be one eminently suitable for medical treatment. Unfortunately, as the man was a bus conductor, his meals were taken at very irregular hours, and he pointed out that it would be impossible for him to diet or to obtain food at evenly spaced intervals. He was therefore informed of the uncertainty of surgical measures, but nevertheless agreed to operation. At operation a medium-sized, indurated ulcer was found at the junction of the first and second parts of the duodenum on the anterior surface, and a posterior gastrojejunostomy was performed. There were no further digestive symptoms for some 2½ years, but the abdominal pain then recurred, coming on 1-2 hours after food, and being relieved by more food or by alkaline powders. Two months before admission in December, 1930, there had been blood-stained vomit and melæna, and the patient had been losing weight. On admission a second operation was performed. The posterior gastrojejunostomy stoma was found to be patent and working well. On the anterior wall of the duodenum, this time at the pylorus, an active indurated ulcer with adhesions was found. At the junction of the first and second parts of the duodenum a white puckered scar of the original ulcer was easily distinguished. A partial gastrectomy was then performed, the end of the stomach was cut off and closed just below the level of the gastro-enterostomy. Recovery was uninterrupted and the patient was able in due course to take a full diet. Before discharge he had several attacks of diarrhœa with yellowish watery stools. The condition cleared up with medical treatment.

*Condition on admission.*—The patient was pale and sallow and looked ill. The abdomen was considerably distended, free fluid was present, and the legs were œdematous. The urine was free from albumin. Having regard to the history and physical signs, I suggested that this was a case of gastrocolic fistula with concurrent œdema, probably of nutritional type, as was suggested by Dr. Poynton in his case in 1930.

*Special investigations.*—A barium meal showed that a partial gastrectomy had been performed and suggested that an enterocolic fistula might be present. A barium enema was then given but this failed to pass upwards further than the middle of the descending colon, the rectum and sigmoid being much ballooned.

A blood count showed a mild secondary anæmia. The urine contained a few red blood-cells. In the fæces fat was present in excess. The ascitic fluid was clear and, on centrifuging, yielded a few small lymphocytes and large mononuclear cells from the lining of the peritoneum.

*Further progress.*—Vomiting stopped soon after admission until on Sept. 27th the patient vomited some greyish material like soft putty and passed a stool of similar appearance containing an excess of fatty acid crystals. The temperature fluctuated between 98° F. and 101° F. with an occasional rise to 102° F. He was unwilling to undergo an operation and I did not consider that it was justifiable to press for it, as I felt that the chances of survival were slender. On Oct. 18th the man complained of nausea and vomited again. His condition became rapidly worse, the temperature rising to 104° F. and the pulse-rate to 120, and he died next day.

## POST-MORTEM FINDINGS

Dr. E. J. Dennison, the senior house surgeon, performed an autopsy.

The body was much emaciated, with oedema of both feet and ankles, and abdominal enlargement. There was an old operation scar in the upper abdomen. About a pint of straw-coloured fluid was found in the peritoneal cavity, and in the left hypochondrium there was a large indurated adherent mass consisting of stomach, small intestine, and large intestine. There was some muddy black fluid surrounding the indurated mass, which had evidently leaked out from some part of the intestine.

(a) Probe in gastrocolic fistula. (b) Probe in gastrojejunal communication. (c) Site of terminal perforation into peritoneum (cut edges are caused by removal of portion for section). (d) Stomach. (e) Colon. (f) Jejunum.

On further examination an old gastro-enterostomy was found, the suture line having become adherent to and ulcerated through into the transverse colon. This ulceration was evidently of fairly long standing. In addition there was a recent perforation in the same region into the peritoneal cavity. Thus a probe inserted into the stomach could be passed with ease into the jejunum, transverse colon, or peritoneal cavity. The only abnormality in the thorax was an old tuberculous focus in the apex of the right lung, a piece of which was removed for section.

Dr. Little examined the specimens removed. The stomach, colon, and jejunum involved are illustrated in the accompanying Figure. There was a common communicating passage, about 1 in. in diameter, between the stomach, the jejunum, and the colon. At the further edge of the gastro-jejunal communication was a perforation of about a quarter of an inch in width with bile-stained edges.

Sections were made through the gastrojejunal junction and the gastrocolic junction. In the former the mucous membrane of the one passed imperceptibly into that of the other, while the fusion of the underlying muscular layers could only just be made out from the slight irregularity of the muscle bands and the presence of a little fibrous tissue. In the latter a small depressed area of surface necrosis showed where the mucous membrane of stomach and colon met.

In the portion of lung removed were healed and active tubercles.

## SURGICAL ASPECT

The interest in this case from a surgical point of view is that, although it was in every other way suitable for medical treatment, yet the man's occupation as a bus conductor rendered this impossible.

Surgical treatment was therefore undertaken, and for 2½ years he remained symptom-free; the original duodenal ulcer was actually healed and there was no sign of the formation of a gastrojejunal ulcer. When another ulcer did form, it formed at the pylorus and not at the site of the anastomosis. Later, however, when a partial gastrectomy was performed a gastro-jejunal ulcer appeared which ultimately led to the death of the patient. In retrospect there seems to be no doubt that the correct treatment of the condition was medical and not surgical, and that when the patient was first seen he should have been advised to give up his occupation which was obviously unsuitable and in large part the cause of his trouble. Such advice, easy enough to give, would have been difficult to follow during the period of economic depression when the patient first attended hospital.

## BILATERAL HERPES ZOSTER OF THE TRIGEMINAL NERVE

BY R. M. CAMPBELL, M.B. Aberd.

ASSISTANT MEDICAL OFFICER, THE GROVE HOSPITAL (L.C.C.), LONDON, S.W.

BILATERAL involvement of all the divisions of the trigeminal nerve is a sufficiently rare manifestation of herpes zoster to justify the publication of a single case.

The patient was a male, mentally defective child, aged 6 years, to whom diphtheria antitoxin had been administered before admission to hospital because of a profuse mucopurulent nasal discharge of three days' duration. There was no previous illness. On admission the only physical signs of note were a temperature of 102° F., slight faucial congestion, small patches of exudate on the tonsils and uvula, and slight bilateral enlargement of the tonsillar glands. During the night the child had profuse diarrhoea, the stools being green and frequent without visible blood or mucus. On the following morning the temperature subsided by crisis. Cultural examination of the throat and nose failed to confirm the diagnosis of diphtheria.

On the second day, circumscribed raised areas of erythema, each half an inch or more in diameter, were observed on the face. The eruption was strictly symmetrical on the two sides, being distributed on the forehead, nose, cheeks, malar regions, and upper and lower lips. The symmetry of the lesions and their strict localisation to the sensory area of the trigeminal nerve were striking. Small and large vesicles appeared on the erythematous bases by the following morning. At the same time small shotty glands were palpable in the posterior cervical chains. Rupture of the vesicles and crusting were completed by the eighth day. The cornea was not involved, and no lesions were visible in the mouth or fauces. No abnormality was found on general examination of the central nervous system. Scarring following the healing of the herpetic areas was slight, and no sensory or motor impairment of the cranial nerve functions resulted.

Unlike herpes simplex, herpes zoster is rarely bilateral, and it has been estimated that only some 30 instances of this unusual condition have been reported. Among 140 cases of zoster personally observed by Glauberson,<sup>1</sup> only two showed an affection of the same or different segmental areas on the two sides of the body.

Similar examples have been recorded in this country by Fordyce<sup>2</sup> and Fox.<sup>3</sup> Hutton<sup>4</sup> described a case

of bilateral zoster with a concurrent varicelliform eruption. Bilateral facial herpes affecting the pinnæ of the ears and the parotid regions was noted by Burgess.<sup>5</sup> A review of the available literature has resulted in the discovery of one reported case with a bilateral involvement of the whole of the trigeminal nerve areas as in our patient; in a brief annotation Anderson<sup>6</sup> mentions the occurrence of bilateral trigeminal zoster in a woman suffering from a cerebral abscess. In our patient the features are compatible with a primary infection of the Gasserian ganglia

of the trigeminal nerve by the unknown virus of herpes zoster.

I am indebted to Dr. J. S. Anderson, medical superintendent of the Grove Hospital, for permission to publish this case.

## MEDICAL SOCIETIES

## ROYAL SOCIETY OF MEDICINE

## SECTION OF LARYNGOLOGY

At a meeting of this section held on May 1st, with Mr. LIONEL COLLEDGE, the president, in the chair, Dr. G. V. T. BORRIES (Copenhagen) opened a discussion on

**Headache Associated with Disease in the Nose**

He said that according to the text-books the chief causes of such headaches are sinusitis, adenoids and other forms of nasal obstruction, and acute coryza. With modern methods of diagnosis, unsuspected infected sinuses were disclosed more frequently, and, if these had been a cause of headache, a dramatic cure could be effected. This circumstance had served to obscure other causes and had led rhinologists astray. In Dr. Borries's experience the treatment of latent sinusitis did not often result in the cure of headache, and on the other hand other rhinogenous causes of headache were often neglected. A frequent form of headache occurred during and after the common cold following congestion of the middle turbinal. Such a headache might be very severe and prolonged, but could always be cured by simple means, however long it had been present. The question of an allergic cause may arise, but Dr. Borries proposed in this communication to consider only rhinogenous causes excluding sinusitis. In diagnosis the site of the headache was important; the pain was situated about the eye and in the occipital region of the same side. There was also tenderness over the inner palpebral ligament. The headache appeared with coryza; improvement was associated with shrinkage of the middle turbinal and reappeared when this had worn off. There were, however, also less clear-cut cases. Often a diagnosis of hysteria was made which gave satisfaction as confirming the secret beliefs of relatives, but real headache was hardly ever due to hysteria. Treatment was at first conservative, consisting in the dilatation of the middle meatus with cocaine. Dr. Borries quoted cases showing that this alone often succeeded. He used 5 per cent. or 10 per cent. cocaine without adrenaline, and the fact that atropine was frequently beneficial seemed to favour the hyperæmic theory of origin. Where further measures were necessary he advocated partial or total resection of the middle turbinal with submucous resection of the septum where a deflection of the latter was helping to encroach upon the middle meatus. Sometimes a diseased inferior turbinal was keeping up infection and might therefore need either cauterisation or partial reduction. Physical treatment was often required to supplement operative treatment. The occipital myalgia might be analogous to myalgias elsewhere, for example, pleurodynia and sciatica. Dr.

Borries quoted a case where a mastoid operation had twice been performed for myalgia in the muscles of the auricle. The occipital muscles might be a reflexogenic site; in one case pressure on the occipital region relieved the maxillary pain which reappeared on its cessation. Another patient complained of pain in the neck while a middle turbinal was being removed, and pain in the shoulder might accompany maxillary pain. In connexion with the site of the pain it was noteworthy that the area of pain in a sinusitis did not always correspond with the sinus affected. Massage and "shock" therapy could be tried, and a prolonged after-treatment of the myalgia might be necessary. The patients were often susceptible to variations in temperature and must guard against this; measures designed to harden the resistance to weather conditions were useful. Certain patients had a high degree of sensitivity and hyperæsthesia, and cocaine tampons must be cautiously introduced, perhaps preceded by a spray of anæsthetising solution. It might be difficult to draw a sharp line between headache due to sinusitis and that due to other forms of rhinogenous headache. One important condition sometimes associated with headache, namely, conjunctivitis, was occasionally rhinogenous, and cleared up with the treatment of the nasal condition. Dr. Borries wished to emphasise the fact that a headache could be rhinogenous even if rhinoscopy and X rays reveal no obvious abnormality.

Mr. F. J. CLEMINSON (London) said that pain of this sort was very difficult to explain. There are several different types. Radiation from the teeth was a common one, and this might spread from the face and head to the shoulder, and down the arm into the fingers. Sometimes this occurred with an infected sinus, but more often sinus pain was localised. Although pain in the ear was not generally given as a symptom of sinusitis it was occasionally found; a striking case of this sort in a doctor came under the speaker's observation some time ago. Such pain was seldom entirely confined to the ear. It could be understood by studying the connexions of the great superficial petrosal nerve and Arnold's nerve with the sphenopalatine ganglion. Pain down the arm and in the neck might be due to the presence of vagal and sympathetic afferents in the nerve of Wisberg, and might thus be analogous to cardiac referred pain; it must be remembered that the heart was a cervical rather than a thoracic structure. Mr. Cleminson described a case illustrating vacuum pain from an infected maxillary sinus, and another where frontal pain was found to be due to an apical abscess. He had frequently met with occipital pain. Connexions of the fifth cranial nerve in the upper cervical portion of the spinal cord possibly provided the mechanism of production. He felt that myalgia and myositis were not adequate explanations.

Dr. GAVIN YOUNG (Glasgow) said that he would deal only with headache due to chronic nasal disease. There were two reasons why the upper portion of the nose was chiefly responsible: it was narrower and contained narrow channels between the ethmoidal bones, and the sinuses opened into it. Engorgement of the mucous membrane of the middle turbinal might arise from infection or from allergy. High deviation of the septum might be a contributory cause through pressure on the middle turbinal of one side with hypertrophy of the opposite middle turbinal. A form of vacuum headache might be due to this cause. Submucous resection of the septum was the most suitable treatment. For antral or frontal sinus infection, the Caldwell-Luc operation and an external frontal operation were respectively the operations of choice. Allergy accounted for a number of cases, and often no structural deformity or infection could be made out, but congestion could sometimes be provoked by touching an area on the septum or middle turbinal. Polypi rarely caused headache, and that occurring in atrophic rhinitis might be due to the column of cold air constantly impinging on an inflamed surface. Headache associated with adenoidal hypertrophy was a clinical observation dating from Hippocrates, and was possibly due to the narrowed nasal passages. Sudden lancinating pain in the face of psychogenic origin had often occurred in his experience, occasionally with some slight nasal abnormality, but careful questioning served to separate the factors.

Mr. HERBERT TILLEY (London) said that the swelling of the anterior end of the middle turbinal described by Dr. Borries was the first stage of ethmoidal infection. If the patient was seen a year later, the mucosa was found to be wrinkled with perhaps a little crusting, and, later still, it might show small polypoidal granulations or even frank polypi. He believed this condition to be due to a non-suppurative infection of the mucoperiosteum and bone. He showed sections which supported this theory, showing superficial infiltration with organisms of bone taken from the ethmoidal region of patients with headache. The occasional recurrence of headaches after radical operations might be explicable by this theory of infection, and it also emphasised the value of a bacteriological examination of sinus washings.

Miss ROSA FORD (London) discussed the two cases she had shown of headache and retrobulbar neuritis in which she had diagnosed sinusitis (previously unsuspected) on the restriction of the fields of vision. With conservative treatment to promote drainage in the nose she had obtained a permanent cure in both cases.

Dr. F. A. PICKWORTH (Birmingham) showed lantern slides of X rays of the sphenoidal sinuses after lipiodol injection taken before and after the occurrence of headache. Immediately after headache had occurred the mucosa of the sinus had swollen up, especially near the ostium, and the lipiodol was seen to be squeezed into a thin stream. This might also occur elsewhere, and the speaker considered that it was important to take X rays of this type before and immediately after the occurrence of headache.

In reply, Dr. BORRIES said that he believed psychogenic headache to be rare. It occurred chiefly in women, and there might be an endocrinological factor. He pointed out that occipital pain, which he held to be reflex in origin, could be present only

on one side and not on the other, and that it could be relieved by pressure.

Mr. CLEMINSON said that referred pain was generally accompanied by tenderness, and, as a rule in these cases, the occipital region was not tender.

#### SECTION OF OTOLOGY

At a meeting of this section on May 1st, with Mr. HAROLD KISCH, the president, in the chair, a paper on

#### Diagnostic Problems in Orogenous Intracranial Complications

was read by Dr. G. V. T. BORRIES (Copenhagen). He began by speaking of a type of case in which either suddenly or after a spell of Cheyne-Stokes respiration the patient ceased to breathe, and became cyanotic and unconscious. In the absence of active treatment death quickly supervened. At autopsy the lobes of the cerebellum were found to be pressed down in the foramen magnum, the lateral ventricles were dilated, and the brain tissue was oedematous. It was curious that so many text-books of all countries omitted all mention of this complication of otogenic infection. In 1919 Dr. Borries treated a case of the kind in which respiratory paralysis came on suddenly. He at once started artificial respiration, and while his assistant kept this up he himself did a craniotomy on the right side, evacuating a large cerebral abscess. After that, the respiration was restored and continued until next morning, when the patient died. The number of such cases published was 47; in many of them the diagnosis was not made before death, and in only 21 was there an attempt to open the abscess. The suffocation was often interpreted as due to a laryngeal spasm; especially was this so when respiration ceased under narcosis, leading in 7 cases to the performance of tracheotomy. Sometimes it was attributed to the death agony, and hence no operation was undertaken. It should be recognised (1) that sudden cyanosis in an otogenous brain affection meant respiratory paralysis, most often due to a cerebellar abscess; (2) that the treatment consisted in artificial respiration and evacuation of the abscess; and (3) that sudden death in bed in cases of otogenous cerebral lesions was mostly due to respiratory paralysis, which in turn was caused by cerebellar abscess. Bradycardia was a symptom which in this connexion scarcely received any mention in text-books. If a patient with otitis had slowness of pulse it was usually regarded as a sign of increased intracranial pressure. Careful investigation had shown him that a slow pulse was a very common symptom in the serous stage of acute labyrinthitis; collecting the figures of four authorities it was found that 32 of a total of 80 cases showed it. Bradycardia was encountered also in vascularised labyrinthine fistulae, and in association with iridocyclitis. In case of facial paralysis of uncertain origin tetanus was a possible cause; it might originate from middle-ear suppuration without any known trauma.

Turning to the differential diagnosis between brain abscess and meningitis, Dr. Borries said that in 1900 a case was reported in which a man with typical signs of diffuse otogenous leptomeningitis was found to have an uncomplicated abscess of the brain, with no meningitis. This showed that though there might be no visible meningitis, the meninges could nevertheless be inflamed. The question arose whether it was possible clinically to demonstrate

such an abscess. His contention was that the meningitis induced by a brain abscess was sometimes not identical with the ordinary meningitis induced directly by mastoiditis, and could be differentiated clinically. Its special features were its strikingly benign course and its independence of other conditions. In some cases of cerebral abscess the successive specimens of cerebro-spinal fluid became ever clearer, although the abscess was not opened. The explanation seemed to be that the abscess attenuated the virulence of the organisms and toxins passing through it. A non-purulent inflammation of the brain tissue was not to be regarded as a special disease, but merely a preliminary stage of abscess formation.

An important question was: When ought one to attribute mild encephalitic symptoms to a so-called serous or simple encephalitis, and when to a hæmorrhagic encephalitis? It was safe, he thought, to assume that in the severe cases the condition was usually hæmorrhagic, but it was uncertain whether a simple non-hæmorrhagic encephalitis might not also give rise to focal symptoms. Probably both simple and hæmorrhagic encephalitis might produce them, but very pronounced focal symptoms were suggestive of hæmorrhagic encephalitis. Often the symptoms were very slight and not very typical; now and then cases were encountered with indefinite or vague cerebral symptoms and optic neuritis, the spinal fluid was normal, and the patient recovered. His view was that most of those patients had encephalitis. In the more severe and pronounced cases it could generally be said that the symptoms were the same as those of brain abscess. Only when the facts compelled the otologist to adopt a new point of view did he realise that the old nosological entities did not suffice, that there was a missing link which also must be taken into account in clinical work, and that that link was non-suppurative encephalitis. Recognition of that disease he regarded as very important, not only in diagnosis but also in treatment. For example, in a case with hemiplegia and aphasia, if the possibility of a non-purulent encephalitis was not taken into account as a cause of such symptoms, it might be thought that the patient's only chance depended on the finding of an abscess, and this might lead to deeper and repeated punctures being carried out—perhaps with serious results. Its recognition would also modify the prognosis, for experience had shown that in even apparently hopeless cases of encephalitis, with hemiplegia and aphasia, complete recovery might take place. The time had come when otogenous non-purulent encephalitis must be established as a clinical entity.

Mr. ERIC WATSON-WILLIAMS (Bristol) spoke of a case of labyrinthitis under his care, the onset of which was signalled by bradycardia. This sign might be present, too, in acute sinus disease. Among his cases of intracranial suppuration there had been one or two with extreme pulsus paradoxus; in one the pulse varied between 60 and 80 in inspiration and expiration. When nystagmus was noticed after operation the possibility must be remembered that it was really congenital; in which case there would be no vertigo. He thought that the chief point made by Dr. Borries concerned the distinction between brain abscess and meningitis. That was a problem which might arise at any moment, perhaps in the small hours of the morning when laboratory resources were not available. If the patient was in coma and there was no history, one had to rely largely on the clinical signs and the results of lumbar

puncture. When a cerebellar abscess was suspected he always did lumbar puncture with trepidation, postponing it until the patient was on the operating table. In differential diagnosis he laid stress on the chloride content of the fluid; but he had seen several cases of meningitis in which, in early stages, the chloride had not been reduced. By the time a patient presented the text-book clinical picture of meningitis, the opportunity for successful intervention had probably gone by.

Mr. E. D. D. DAVIS said that patients with cerebellar abscess had left hospital and later died suddenly—no signs of abscess having appeared. With abscesses in the brain it was best to defer operation until the pus became localised and the signs were definite. He regarded lumbar puncture as very valuable, and had never known any harm arise from the diagnostic removal of small quantities of fluid. One of the early symptoms of meningitis was severe headache and slight mental change.

Dr. RITCHIE RODGER said that Macewen's remarkably good results in intracranial suppuration had been attributed by others to his having operated on most of his cases at a late stage.

Mr. SYDNEY SCOTT had never seen a case of brain abscess associated with the presence of the tetanus bacillus, but within recent years he had encountered four in which there was anaerobic infection, all of them fatal. He recalled a case in which a woman had a frontal sinus infection, with aphonia and symptoms which led to the suspicion that she had a frontal brain abscess. Sir Percy Sargent, however, preferred to have the frontal sinus operated upon externally first, and that was done, the dura mater not being touched. There were a number of postponements of the larger operation, and eventually the patient made a complete recovery without anything further being done.

Dr. BORRIES, in reply, said that in studying the pulse-rate it was necessary to take a reading at least every hour, so as to detect periods of exceptional slowness. The serous stage of labyrinthitis was a very short one, perhaps not longer than half a day. In purulent labyrinthitis a slow pulse was detectable only in the early stage. In doubtful cases he liked to take two or more specimens of the spinal fluid and correlate the results with the clinical symptoms.

### Hearing Aids

Mr. TERENCE CAWTHORNE read a paper on the prescribing of hearing aids. It was probable, he said, that in the past otologists had given less attention to this part of their work than to any other. A consequence of this neglect was that sufferers had often turned to the makers of advertised apparatus. The provision of an aid was advisable when the hearing defect was such that, despite treatment, normal methods of communication were either impossible or irksome. Correction of the defect presented many problems as yet unsolved, but the invention of the thermionic valve had so increased the amplification of sound that already there had been a great increase in the efficiency of hearing aids, and in the not distant future as good results might be expected from them as were obtained with glasses for defective sight. An essential preliminary was a reasonably exact method of estimating the auditory capacity of the person concerned, both for speech and for the audible range of pure tones. The method should lend itself to accurate reproduction, so that any improvement in the range of hearing could be

measured. In addition to the routine tests with the voice, tuning-forks, or the audiometer, special speech articulation tests—consisting of single syllables chosen to accentuate certain vowels and consonants—were of great value in determining the efficiency of an aid. All patients with pure middle-ear deafness were able to derive benefit from using an aid. In cases where there was less than 50 per cent. of cochlear function, the degree of amplification required of an aid would be such that its intensity would approach the upper threshold of hearing, and the result would be confusion and perhaps discomfort.

The hearing aids themselves could be classed as electrical and non-electrical. The latter included horns, auricles, and speaking-tubes, and their function was to collect and conduct sounds, and occasionally to act as resonators. Their amplifying power was limited, but their attractions included low cost, freedom from sound-distortion and from adventitious sounds, and the fact that no upkeep was necessary.

The electrical aids consisted essentially of a microphone, an amplifying circuit, and a receiver, the first being the most important. In the telephone type a carbon-granule microphone was used, with a small dry cell and amplifier, and though it was difficult to keep this type free from distortion and from adventitious noises, some patients were ready to overlook those disadvantages in view of its portability and relatively low cost. The employment of valves rendered faithful and noiseless amplification possible, and aids embodying them surpassed anything else so far achieved. At the moment their use was limited by their size, and by the initial cost (£12-£25) and cost of upkeep. For individual speech, a speaking-tube or trumpet was usually adequate; for general conversation or for use in church or theatre a valve aid was by far the best. If the aid was to enable the patient to listen to one particular voice, the pitch of that voice must be specially catered for.

## REVIEWS AND NOTICES OF BOOKS

### The Chemistry of Milk

By W. L. DAVIES, Ph.D. Cantab., D.Sc. Wales Research Chemist and Analyst, National Institute for Research in Dairying, Shinfield. London: Chapman and Hall. 1936. Pp. 522. 25s.

DURING the past fifteen or twenty years there has been a great output of published papers on the chemistry and physical chemistry of milk and of milk processing scattered in a variety of scientific journals, agricultural bulletins, trade magazines, and monographs. Of this work some is of fundamental importance including that which has a bearing on human nutrition; some is mainly of agricultural interest and much is of purely commercial significance. The author of the present volume, a well-known authority in the field of dairy research, has undertaken the arduous task of surveying this vast mass of publication, selecting the most significant contributions and bringing the whole within reasonable compass. It seems ungrateful to suggest that while he has done his work of compilation with commendable thoroughness, the process of inspissation has been, in places, too drastic, and so much has been crowded into a paragraph or a section as to destroy clarity.

The book is divided into five sections. In the first the composition of milk is dealt with, particularly the range and causes of variations in chemical composition; recent work on the constituents of milk is then summarised, and the third section is devoted to the physical properties and physical chemistry of milk; the chemistry and chemical technology of milk processing are next considered, whilst the last section provides a useful résumé of published work on the nutritional value of milk constituents and of milk as a whole. In each section Dr. Davies has, in effect, provided a well-documented review of modern work, with here and there a critical assessment of accepted opinion. There are 1400 references, most of them of recent date. Accounts of hitherto unpublished work of the author and of his colleagues at Shinfield are supplied and reference is facilitated by the provision of two indexes, one of subjects and the other of authors.

There are, as might be expected in a volume covering such a vast field, occasional omissions and errors. Thus the important work of Graham and his colleagues on the effect of thyroid feeding and

thyroxine administration on the chemical quality of milk receives no mention, the limits of sensitivity of the phosphatase test for determination of the efficiency of pasteurisation are not given, and the statement is made that casein may be boiled for "a considerable length of time" with 0.1 N alkali without appreciable change.

The present activity in the dairy world, with the growing regard for quality in milk and milk products, and the interest now being taken in the increased consumption of milk in this country make the issue of this book opportune, and it will be welcomed by all those interested in recent advances in knowledge of the chemistry of milk.

### The Medical Treatment of Gallbladder Disease

By MARTIN E. REHFUSS, M.D., Clinical Professor of Medicine at Jefferson Medical College, Philadelphia; and GUY M. NELSON, M.D., Instructor of Medicine at the College. London and Philadelphia: W. B. Saunders Co., Ltd. 1935. Pp. 465. 24s.

In this book the authors have set out to give not only full details of medical treatment of gall-bladder disease, but also a review of the present state of opinion concerning the physiology of the gall-bladder, the metabolism of cholesterol, the genesis of gall-stones, the "infection problem," and other subjects. This is an ambitious undertaking which has not been accomplished with complete success. Of the vast literature on the subject some 500 papers have been selected for inclusion in the bibliography at the end of the book. Unfortunately the authors have exercised little critical faculty in assessing the relative values of these papers; work which most of those in a position to judge regard as misleading is quoted with full approval; in one instance indeed a thesis is based solely on such evidence. We would hesitate to suggest that the omission in places of unpalatable truths which conflict with a theory favoured by the authors is deliberate; but it is certainly likely to mislead readers who are not themselves familiar with the arguments on both sides of controversial questions. Even the sections dealing with treatment, which reflect the outcome of many years of clinical experience, are marred by an attempt to supply a

scientific explanation of observed facts which is not always acceptable. The "low cholesterol diet," for instance, may or may not be essential; it is certainly not essential for the reasons given in its support. In one place we are warned of the danger of using vegetables containing phytosterol, because of what Chauffard said; in another—the bibliography—we find a reference to the author who proved that phytosterol is not absorbed from the intestines.

Yet there can be no doubt that the practical experience reflected in this book, wisely interpreted, will be useful to many. Information on treatments which have been found by experience to benefit patients is always of value. The chief criticism of the methods given in this book is that they err on the side of over-stringency. This is not necessarily a disadvantage; by many patients very exacting instructions about diet, for instance, are welcomed, and most physicians would agree that patients would benefit from a régime such as is here laid down, and might even be saved from the need of an operation. One of the advantages of the book is the admirable detail with which instructions are given; it is by attention to such detail that good results are obtained. We are all apt to forget that what we have learnt after years of study is not by any means as evident to patients. Failure in therapeutics is sometimes the result of telling our patients too little about what they are to do, and too much about the pathology of their condition, which they like to think they understand but almost always misconstrue. In this book, however, the precision of the instructions to be passed on to patients does not seem to be matched by a clear conception of the terminology in use among medical men. To write about "vitiated portal blood," "lithogenesis of the vesicular mucosa," of something being of value "in all sluggish gall-bladder conditions," of "delicate innate forces in the various tissues of the body" helps no one. These are not the phrases used by a scientific physician addressing his fellows. Some of the chapters are excellent, notably that on duodenal intubation, obviously written by one who has had practical experience, and that on jaundice in non-calculous cholecystitis by Dr. A. Cantarow. For English readers the interesting notes on cooking could with advantage have been a little more explicit. A technical term such as "panning" may be full of meaning to an American cook but means little to an English one.

### The Chemical Control of Conception

By J. R. BAKER, M.A., D.Phil., Lecturer in Cytology in the University of Oxford. With a chapter by H. M. CARLETON, M.A., D.Phil., Research Fellow of New College, and Lecturer in Histology, University of Oxford. London: Chapman and Hall. 1935. Pp. 173. 15s.

THIS book gives the results of some eight years' research upon the spermicidal powers of a number of pure chemical substances and of a smaller number of proprietary chemical contraceptives. At intervals during the last five years Dr. Baker has reported his findings in a series of papers, published in the *Journal of Hygiene*, on which we have had occasion to comment, while Dr. Carleton's investigations of the pathological effects of various substances on the mucosæ of the genital tracts of female animals and his experiments on the Gräfenberg ring have been described in the *Journal of Obstetrics and Gynecology*. This book, it should be noted, is not

written for the medical practitioner who wants a straightforward answer to the plain question: What spermicide should I advise my patients to use? It describes the successive stages of the most comprehensive programme of research yet planned with a view to elaborating a chemical spermicide which will prove harmless and yet reliable. This is a field of biological inquiry which has remained almost untouched since the publication in 1907 of the work of Gunther. Dr. Baker's investigations are not yet completed and have not yet revealed an article which fulfils all the requirements. Since the war a steadily increasing interest has been shown in all civilised countries in questions connected with the control of human fertility, and the technical problems of contraception will certainly be studied in all their aspects with growing keenness by a widening circle of investigators. All these will find in Dr. Baker's collected researches a valuable groundwork which they cannot afford to ignore.

### La rate en pathologie sanguine

By ÉMILE HOUCKE, Médecin des Hôpitaux de Lille. Paris: Masson et Cie. 1936. Pp. 154. Fr.45.

THIS small illustrated monograph, one of many of similar type published by Masson in recent years, deals with the pathology of the spleen, and particularly of splenic enlargement, in the diseases which affect the blood-forming organs. The changes in the spleen are broadly considered under four main headings: (1) hæmopoietic reactions, which include myeloid metaplasia in a variety of blood diseases, and the splenic lesion in the leukæmias; (2) splenomegaly with proliferation of the reticulo-endothelial system, in which is included the changes in Hodgkin's disease and the lipoid disturbances of the Gaucher-Pick-Niemann group; (3) reactions following hæmolysis, including acholuric jaundice and Addisonian anæmia; and (4) splenomegaly associated with fibrous and vascular reactions, including the so-called Banti's disease, now more commonly known in this country as hepato-lienal fibrosis. The work here described is founded on observations made in the clinic of Prof. Curtis of Lille (who contributes a preface) during the past ten years, but no statistical records of the numbers treated and practically no clinical details are supplied. Much of the monograph deals with the work of others. There are not many references to foreign literature on the subject. A few German papers are noticed, but there is scarcely any mention of the more important accounts of the varieties of chronic splenomegaly by American, British, and Italian authors. The monograph is, however, useful in so far as it summarises the French outlook and provides a good bibliography of the French literature on the subject.

### Variations in Blood Pressure and Nephritis

*Diagnosis and Treatment.* Third edition. By HERMAN O. MOSENTHAL, M.D., Professor of Medicine and Attending Physician, New York Post-Graduate Medical School and Hospital. London: Humphrey Milford, Oxford University Press. 1936. Pp. 616. 42s.

THIS is a disappointing book. It was apparently planned from the outset with the idea that study of functional pathology (or pathological physiology) is of equal importance to that of morphological pathology. With this conception before him Dr. Mosenthal

has avoided any emphasis of the anatomical changes in the kidneys in Bright's disease and kindred conditions. But there is surely a difference between that wide conception of pathology for which Sir William Gull ably pleaded and the relegation to the dustbin of all the clearer cut distinctions between various types of nephritis which have emerged from the work of modern writers. Are we to revert to some vague general conception of all forms of hypertension, renal œdema, renal failure, and nephritis under the heading "Bright's Disease"? The bad example of the old hæmatologists who took the concept of Addison's anæmia and by remixing it into the general welter of all the grave anæmias arrested the progress of knowledge for decades should not be forgotten. This book has indeed little value for either the student or the graduate. The paragraph on retinitis on page 168 seems altogether inadequate in a section dealing with the prognosis of essential hypertension, and the discussion on the subject on pages 244 and 245 carries the matter but little farther. The sections dealing with œdema are no better. To anyone familiar with modern advances in knowledge about nephritis it must seem amazing that a book which gives a bibliography of 50 to 150 references at the conclusion of each chapter should make no mention of the work of Prof. Govaerts, to give only one example. The sixteenth chapter, which deals with uræmia, whilst endeavouring in an initial section to distinguish between various type of uræmia, fails to give any clear description of the various symptoms which can to-day be exactly ascribed to such different factors as cerebral anæmia, variations in the alkali reserve, calcium deficiency, and urea intoxication. We would, if we could, praise at least the production of this book; but even in this respect it cannot pass muster. There are inexplicable and displeasing variations of the type of paper used: the first 184 pages are grey, the next 350 yellow-white, whilst from page 553-568 we are suddenly faced by eight pages of blue paper.

### Mental Health

By FRANK E. HOWARD, Ph.D., Professor of Education and Psychology; and FREDERICK L. PATRY, M.D., Psychiatrist, State Education Department, University of the State of New York. New York and London: Harper and Brothers. 1935. Pp. 551. 15s.

MENTAL hygiene has suffered a good deal at the hands of friends who claimed too much for it. Such temperate presentations as this may help to restore confidence in its future. The book is based largely on the teaching at the Henry Phipps Psychiatric Clinic at Johns Hopkins Hospital. A preface acknowledging this debt to Prof. Meyer is now a feature of many psychiatric books written in the United States and brings a welcome assurance to the reader that he will not find wild speculations or dogmatic theories, but a well-organised workable approach to the problem of mental health. The adequacy of the general framework of this monograph compensates for an occasional vagueness in expression; in a work not intended for psychiatrists, it is probably wiser to refrain from particularising difficulties and unsolved problems. The emphasis here is on education and on the ways of coping with deviations from normality. One of the authors is an authority on educational psychology and the other a psychiatrist, working principally with children. At the end of each chapter, questions

for discussion offer opportunity for the student to digest what he has read and to apply it to actual problems; there are also valuable lists of papers recommended for further reading. Though somewhat uncritical and rather verbose, the book is as a whole a sensible guide to mental hygiene.

### Practical Clinical Psychiatry

Fourth edition. By EDWARD A. STRECKER, A.M., Sc.D., M.D., Professor of Psychiatry and Chairman of the Department of Psychiatry, School of Medicine, University of Pennsylvania; and FRANKLIN G. EBAUGH, A.B., M.D., Professor of Psychiatry, University of Colorado Medical School. Philadelphia: P. Blakiston's Son and Co. 1935. Pp. 705. \$5.00.

THE new edition of this established text-book has been much enlarged and rewritten. Case records and commentaries on them still make up the bulk of the book, but more space is given to general statements of what is known about each of the reaction-types of psychiatry. A defect in earlier editions is made good by the inclusion of an excellent chapter on the psychopathological problems of childhood by Dr. Leo Kanner. The bibliography of each section is lengthy, and as regards American publications full. The psychobiological point of view is reiterated, so that any student who uses the book is certain to become familiar with the foundation upon which the American school of psychiatry is built. Though of little use as a work of reference, this continues to be an admirable introduction to psychiatry for those who have not yet had the opportunity of working with actual cases under skilled supervision.

### Manipulative Methods in the Treatment of Functional Diseases

By EDWIN L. HOPEWELL-ASH, M.D. Lond., B.S. Lond., Physician-Neurologist to the City of London Red Cross Hospital 1916-18. London: John Bale, Sons and Danielsson Ltd. 1935. Pp. 92. 3s. 6d.

Dr. Hopewell-Ash believes that he has used a manipulative method successfully in the treatment of many functional disorders including melancholia. He claims that there is no organ, no disease, no chemical imbalance which cannot be reached by manipulation or neuromedical treatment which is the application of our knowledge of the reflex effects, through the sympathetic nervous system and endocrine glands, of stimulation of skin areas. Spinal surface manipulation in the manner of Abrams is held to set up reflex responses which ultimately have a tonic therapeutic effect. He does not make clear to the reader how these manipulations are to be carried out, and it still remains to be understood how his method of percussion and massage can produce sympathetic responses capable of permanently breaking up those sympathetic endocrine patterns which have produced the cycle of neurotic symptoms. One might even go further and ask how the complicated submental patterns or complexes which lie at the root of neuroses can equally be resolved by this surface manipulation. Dr. Hopewell-Ash falls back upon the concept of neural energy, but an acceptable neuropsychological explanation of the cures he describes is still to seek.

# THE LANCET

LONDON: SATURDAY, MAY 9, 1936

## EXPANDING PSYCHOTHERAPY

THE Institute of Medical Psychology, which moved only five years ago from its dignified house in Tavistock-square into more commodious premises in Malet-place, is now developing a large extension scheme. A site of 31,400 square feet has been acquired facing Store-street, within a stone's throw of the London School of Hygiene and Tropical Medicine, and on this site it is hoped to build at once a new hostel of 21 beds to take the place of the small in-patients' hostel in Endsleigh-street, the lease of which falls in next year. If all goes well, this will be the first instalment of a scheme for a large educational centre of psychological medicine, to grow up within the shadow of the new central buildings of London University. The extension scheme, which has the blessing of King Edward's Hospital Fund and the interest of the Rockefeller Foundation, will provide equipment for laboratory investigation and research, adequate lecture-rooms, facilities and space for occupational treatment, and the greatly increased number of consulting-rooms in which out-patient and psychotherapist may be brought together without the delay of a long waiting-list. Over 25,000 hours of treatment were given last year; there are nearly 500 patients, adults and children, now under treatment, and the Institute is open from 9 A.M. until 10.30 P.M. And yet it was only possible to open the waiting-list for six weeks in 1935, and the evening waiting-list which had been closed for two years was opened only for three weeks. Both are now closed indefinitely. This is a plain statement of the facts behind a state of affairs which is tragic.

The development of medical psychology in our time has been meteoric and, to paraphrase SCHOPENHAUER'S words, if there were no Tavistock Clinic it would be necessary to invent one. Over 80 medical men and women are working at the Institute and a study of the list of names on pages 2 to 5 of the report suggests that it has included most of the well-known names of those who have devoted their lives to this aspect of medicine. There were not many trained psychologists in London when Dr. CRICHTON-MILLER'S brave scheme first began to take shape, and they were of all grades—Freudian, Jungian, Adlerian, and what not. It was hardly to be expected, or indeed to be desired, that the organisation of the new faculty should follow closely that of the more corporeal form of medical practice. The hospital clinical system can be fairly compared to a herbaceous border, with all the plants of various

shapes and sizes firmly rooted in the soil of pathology, but the Institute more closely resembles the tropical house at Kew where luxuriant growth may be seen at unexpected places and where the brightest flowers spring from stock which has no apparent roots. Few psychologists are pathologically minded, whether by temperament or education, and whatever development may take place there will never be lacking that need for experience in interpretation of pathological findings which is a conspicuous gift of the hospital clinicians of our own time. One of the greatest gains from the new spaciousness should be to give opportunity for work done on pathological lines, as much for the education of the psychologist as for the investigation of the patient. Indeed the development of the educational side is the most hopeful feature of the programme. It is hardly more than a year since the Institute achieved academic status in its recognition by London University for clinical work in the D.P.M. syllabus. The training course for doctors proposing to take up psychotherapy has now been extended from one to two years. And finally the research side of the work has been recognised by the Halley Stewart Trust and the Rockefeller Foundation, both of which have established fellowships at the Institute.

In one other respect the fabric of the Institute differs fundamentally from that of most other medical bodies in this country. During the period of development the Institute was largely under the direction and guidance of an individual mind, and to that fact is due a degree of conscious planning which has delivered the goods although quite alien to any therapeutic system hitherto known. In Dr. REES the founder of the clinic has had a worthy successor. Whether centrifugal direction can safely be maintained is a question which will have to be carefully weighed. The growth of a medical advisory board may indicate that it is likely to give place more and more to the collective responsibility in medical matters which is prevalent elsewhere. But the pioneer work already done by the Institute in its education of social workers, qualified nurses, general practitioners, and would-be psychologists is beyond all praise, and the extension of its usefulness in this direction can have no limit.

## THE LAW OF ABORTION

PROFESSIONAL, even apart from public, interests require the clarification of the law concerning abortion. On this subject the recently issued report<sup>1</sup> of the special committee appointed by the council of the British Medical Association deserves attention. Laws ought to be clear; the law about abortion is obscure. It is not enough to say that in practice the registered medical practitioner is not exposed to prosecution for bona-fide treatment of his patients. Surgeon and physician do not know where they stand. Our judges, who could have given public and authoritative guidance, have added to the confusion. Many distinguished

<sup>1</sup> Brit. Med. Jour., April 25th, Suppl., p. 230.

members of the bench have maintained the traditional legal position that illicit abortion is a grave offence against society as well as, in view of the furtive, unskilled, and insanitary methods of the usual criminal abortionist, a terrible menace to the life and health of the women concerned. Yet one much-respected judge, the late Sir Henry McCardie, seemed often ready to treat an indictment for unlawful abortion as a venial matter hardly distinguishable from birth control and to apply all his judicial authority to hamper the success of a prosecution. Along with this apparent licence to criminal abortionists, there has been an uncomfortable apprehension on the part of the registered practitioner because the law gives him no definite security in the termination of a pregnancy for sound and genuine therapeutic reasons. The profession is aware that bona-fide decisions in the general conduct of medical and surgical practice can lead to exaggerated claims for damages and that, in respect of abortion, criminal prosecution is at any rate a risk. If death follows an operation for the termination of pregnancy, a charge of murder is possible and an inquest may be the opportunity for unwelcome questions and suggestions. Such proceedings may be disastrous to a professional career even if the victim, as the phrase goes, leaves the court without a stain upon his character. The topic of abortion has important religious, economic, and eugenic implications. To the profession it is of immediate personal concern.

The law is to be found in Sections 58 and 59 of the Offences against the Person Act, 1861. There is no need now to go back into the ancient history of ecclesiastical offences. In 1828 Parliament imposed the death penalty for unlawfully and maliciously administering poison or any other noxious thing, or using an instrument or any other means, with intent to procure the miscarriage of a woman quick with child. If the woman was not quick with child, the punishment could be 14 years' transportation and a public whipping. In the general revision of the criminal law in 1861 these provisions were replaced; the unlawful administering of poison or other noxious things, and the unlawful use of instruments or other means, with intent to procure abortion, is now punishable with three years' penal servitude. Commenting on this enactment some years ago,<sup>2</sup> we suggested that, if the statute were nowadays re-enacted, one might expect that an express proviso would be inserted to exempt from criminal liability the fully qualified practitioner who terminated a pregnancy for the bona-fide purpose of preserving the mother from special danger to life or health. The suggestion was justified soon afterwards when the Infant Life (Preservation) Act of 1929, while punishing the wilful destruction of a child capable of being born alive, added a proviso to exempt acts "done in good faith for the purpose only of preserving the life of the mother." It is arguable that this exemption would give like protection against the penalties of the Act of

1861. The professional man is entitled to some closer definition of what is "unlawful" in that Act. If his honest efforts to save the life or health of the mother are (as they surely must be) lawful, those who frame and administer our laws should make the position plain.

Of the moral and religious aspects of the matter there is here no need to speak. Exact statistics of the prevalence and danger of illicit interference with pregnancy may be lacking, but clinical experience in hospitals has its own knowledge of sepsis as a contributory cause of mortality. Public views may vary between that of Tsarist Russia where abortion was punished by solitary confinement and of the Soviet's modern legislation which makes abortion free and permissible in public hospitals while forbidding it to unqualified practitioners. If there is to be any revolutionary change in the law of our own country, feminine opinion, never so well organised or so articulate as to-day, will no doubt be heard. The problem to which we draw attention is a limited one—how is the doctor to be given confidence that the termination of pregnancy on solid bona-fide grounds of therapeutic urgency shall not expose him to the risk of prosecution? Compulsory notification, though it might go far to abolish the grave public dangers of unskilled secret abortion, may be ruled out as impracticable. The confirmation of professional decisions by a second opinion is worth consideration. The recent report of the special committee suggests that a doctor contemplating therapeutic abortion might be obliged to obtain the sanction of a professional colleague of recognised status, on the analogy of "approved" practitioners under the Mental Treatment Act. This specific safeguard should, we think, be thoroughly examined. It would at least enable the doctor to concentrate upon his proper duty to his patient without distracting visions of judges and juries reviewing his decision at the assizes.

## HUMAN ENDURANCE

As a rule human beings employ only a small part of the resources—physical certainly, less obviously mental—which they in fact possess and which can be mobilised for emergency. We live in a state of inhibition or control, a state which is usually identified by the evidence of its removal in so-called superhuman efforts, though exemplified in its extreme or pathological form by the hysteric or the victim of neurosis afflicted with abulia or a sense of chronic fatigue.

In certain circumstances the limits of human endurance appear to be amenable to exact measurement or estimation. Thus, no athlete has as yet succeeded with certainty in running twelve miles within the hour, although a bare half-dozen figure in the records with performances a couple of hundred yards or so short of this distance. In a "go as you please" contest over six days, 624 miles have been covered. Unsited as he is for an amphibian existence, man has swum over 27 hours in a successful crossing of the Channel. Two teams once contested a tug-of-war pull for

<sup>2</sup> THE LANCET, 1927, I., 237.

2 hours 41 minutes. Club-swinging continuously for over 130 hours has on more than one occasion been achieved, and 120 hours' uninterrupted piano-playing appears to be the record for this peculiar attempt at distinction. But the attention is more closely riveted, interest more actively stimulated, by examples of endurance which are outside the sphere of direct measurement: the endurance of cold, of starvation, and of other forms of physical suffering, coupled with extreme anxiety, in shipwrecks, polar expeditions, sieges, and the like. The rescue recently of two of the three men entombed for ten days in a Nova Scotian gold-mine encourages a reference to other, now classical, adventures in an attempt to gain some impression of what men in extremity can endure, to what extent the spark of life can flicker, eventually to kindle once more to a steady flame. Some thirty years ago, after a colliery explosion at Courières in France, rescuers after twenty days of excavation heard the voice of the first survivor, who had taken charge of thirteen others in the darkness and by his courage and example brought them to safety. Five days later, endurance of another kind was exemplified by the exhumation of another survivor who, isolated, had been able to sleep away most of his period of incarceration. Under excitement, again, the organism can perform its physiological functions in a profoundly altered manner, when for weeks and months the drain upon the reserves becomes deeper and deeper. WILLIAM JAMES<sup>1</sup> quotes part of a private letter from Colonel BAIRD SMITH written shortly after six weeks' siege of Delhi in 1857. The gallant officer, to whom the victorious issue was largely due, describes his condition of scurvy, of gangrene of a leg, and of incessant diarrhoea, with complete annihilation of appetite, when for the whole of the siege he lived on brandy and opium. Yet he observes that his sensation of suffering was almost negligible. The excitement of his work was so great that he had never found his intellect clearer nor his nerves stronger. Presumably, as JAMES puts it, Colonel SMITH, having to draw on altogether extraordinary stores of energy, found that brandy and opium were ways of throwing them into gear. With the cessation of the emergency, in a moment all desire for stimulation ceased and a loathing of his late staff of life took possession of him.

The acme of endurance is probably reached at what is for convenience described as early middle age. The veteran in sport often succeeds by virtue of his experience when the superior speed of his more youthful opponent is associated with an impetuosity which leads to an earlier fatigue. "Too old at forty" may be applicable to enterprises in which carelessness is not a liability and speed is essential. But the advantage of the veteran is often attributable to his greater experience; not merely the acquisition of technique or of judgment in employing his physical resources to the best advantage, but a sort of individual cell education automatically acquired as the result

of continued training and automatically utilised. SCOTT'S pathetic cry will be recalled; it was not the older men who failed first, he said—anticipating a criticism that the success of his South Pole Expedition may have been jeopardised by an unwise selection of relatively old leaders. In comparing the sexes, tradition at any rate would assume male superiority; yet the capacity of woman for prolonged endurance of moderate degree is demonstrated in several directions, and she excels man in her ability to maintain prolonged moral excitement as when she takes complete control and support of a poor household—nursing, cooking, cleaning, as well as providing the means for existence by undertaking outside work. It is open to speculation whether crises cannot almost instantaneously awaken processes similar to those reached by yoga-practice only after years of painstaking discipline and training.

### TRAVELLING RESEARCH FELLOWSHIPS

THE decision of the Rockefeller Foundation to abandon the financing of international fellowships in order to concentrate on a more restricted programme for the promotion of medical research was the subject of comment in the report of the Medical Research Council for 1934-35.<sup>1</sup> The Council, who since 1923 had been entrusted with the responsibility of selecting the British Fellows, expressed regret at this change of policy and recalled the success achieved by the 70 men and women who had completed their tenure of these travelling fellowships. An analysis made in 1933 of the positions occupied by them showed that 12 held university chairs, 36 whole-time appointments for higher teaching and research, and a further 16 held part-time appointments of this nature. It would have been most unfortunate if a scheme which had proved so fruitful had been allowed to lapse, especially as the Council now possess the experience, the administrative machinery, and the contacts with centres of recruitment which enables them to choose the most promising candidates. They have therefore been alert to devise a new scheme for the provision of fellowships of a corresponding grade—i.e., with an annual value of approximately £400, besides a grant for travelling and other expenses, and it is now announced that at least eight travelling fellowships will be available for the academic year 1936-37, for which applications must reach the Council by June 1st, 1936. At least three of these (two or more awarded by the Medical Research Council and one by the trustees of the late Lord Leverhulme) will be for the study of any branch of medical science, including clinical medicine and surgery; four will be Dorothy Temple Cross Research Fellowships for the study of tuberculosis; and others, the exact number being unspecified, will be awarded on the recommendation of the Council for the study of psychiatry and neurology, including neurosurgery. The advantage of providing many fellowships on identical terms, and on the basis of a single series of applications, is clear; but potential benefactors should note that the name of any body or person making or leaving a permanent endowment for this purpose, or offering an income at the rate of £500 a year for a specified period would be associated with a fellowship. It would be impossible to find a better way of helping to extend medical knowledge and coöperation.

## ANNOTATIONS

## THE ROYAL ACADEMY

THE exhibition of the Royal Academy of Arts, which was opened to the public on Monday last, provides evidence of much contemporary talent. It is of an inclusive character, pictures on the walls representing many and varied directions of thought and fields of accomplishment. This opportunity for eclecticism is given by two things. First, large pictures are not being painted because houses are not being built to hold them, so that canvases measuring 150 ft. square are now rarely submitted, and mainly in response to commissions for the portrayal of national events. Of such we have four illustrations: Mr. Frank Salisbury's "Heart of the Empire," a graphic record of the national jubilee thanksgiving service at St. Paul's Cathedral; two pictures of the lying-in-state in Westminster Hall by respectively Mr. F. E. Beresford and Mr. F. W. Elwell; and a picture of King George's funeral procession. In all of these the artists have been able to render the proper spirit of the occasions. Secondly, artists who by their position within the Academy can exhibit without question of a jury have latterly been unselfish in the exercise of the privilege. The present exhibition has lost the appearance of overcrowding which used to be depressing, while a wider prospect for new talent is offered.

The direct interest of the medical profession in the exhibition is less marked than usual through the practical absence of medical portraits. What there are are worth noting. There is a drawing in chalk by Mrs. Catherine Dodgson of Sir Thomas Barlow, which is an excellent portrait, a characteristic expression of shrewd and courteous attention being well caught. A bust in bronze of Sir Almroth Wright by Mr. Donald Gilbert is an effective piece of work; the presentation is rugged but the suggestion of a commencing smile in a severe face is expressed. Miss Isabella Reid shows a capable portrait of Prof. R. W. Reid. A portrait of Dr. M. K. Martyn by Mr. James Dawson is a particularly pleasing colour arrangement of browns, greens, and grey. There are two subject pictures having relation to the medical life and both are successful pieces of painting, though neither is much what would be expected from the title. Mr. Kynnersley Kirby's "Village Doctor" sits at a desk which may bear medical records, but is chiefly adorned by a large blue jug and a glass. The doctor's face is cheerful, and the flower in his buttonhole emphasises the gay impression, but to look at he is hardly a typical village doctor, and the microscope in the background somehow looks out of place. And if this picture is not what we should expect from the title, still more so is Miss Golden's water-colour, entitled "The Doctor's House," not typical of the subject. Few medical men, we think, can be so charmingly housed. Pathetic interest attaches to the water-colour drawing of Llanthony Abbey by Sir Wilmot Herringham, who died a week before the exhibition was opened. "L'Infirmière," by the late Miss Beatrice How, which has been acquired by the Academy under the terms of the Chantrey bequest, is a charming little picture. In subdued colour and with simple drawing, this tender illustration of hospital nurse and infant is happily indicated. The protective attitude of the nurse and the curiosity of the child—the two prominent emotions that might be expected—are well rendered, without overstress or sentiment.

Turning to the architectural room we have testimony to the brave rebuilding that is now going on, evidenced by drawings of the new department of massage and medical electricity at the London Hospital, of the paying patients' block at University College Hospital, of the new nurses' home at St. Mary's Hospital, and of the nurses' home at the Masonic Hospital in Ravenscourt Park.

A favourable verdict on the exhibition will be generally given. There may be nothing on the walls that arrests the eye by outstanding merit, or that challenges attention by loveliness, by eccentricity, or by appeal to detective ability. There is nothing that will be nicknamed "the picture of the year," but the 168th exhibition of the Royal Academy obtains a special character from the competence and beauty of many of the English landscapes.

## BENIGN LESIONS OF THE BREAST

Dr. Dupuy de Frenelle<sup>1</sup> is a firm advocate of extensive operation for benign tumours of the breast; only by free excision does he consider that he has safeguarded the patient from the danger of cancer. His advice is to excise all chronic breast lesions, because they may be the starting-point of malignant change; to excise freely, because the histological appearance is so often much less benign than the clinical examination had suggested; and, finally, to remove with the affected part of the breast its lymphatic pedicle, because, on occasion, the axillary glands have been shown to contain metastases when no malignant change was found in the breast itself. He condemns the attitude that shelves immediate decision by "watching" the patient in the hope that subsequent development of the breast condition may give further guidance. It is evident that Dr. de Frenelle has no faith in clinical tests as a means of detecting early malignancy. Even if he had, it would not shake him in his belief in extensive operation, for to him every benign lesion is a potential carcinoma. His advocacy of these methods before the Société des Chirurgiens has evidently called forth a good deal of criticism. The attitude of his critics is that the lesion is either benign, in which case operation is out of place, or that it is malignant, and then radical amputation is the proper course. In the main, of course, the discussion centres round the cases of so-called chronic mastitis. It is not the bilateral symmetrical affection of the breasts, involving most of their substance, and described by de Frenelle as being essentially a loss of suppleness, that he is considering, but the breast with a localised area which feels different from the rest of its substance. The sensation to palpation may be of firmness, of numerous little granules, or of surface irregularity. So long as the granules feel as if they can be separated and the firm area seems to spread out evenly under the hand, de Frenelle follows Delbet<sup>2</sup> in regarding the lesion as still innocent. But in the middle there may be a part in which the granules feel confluent, and there is felt an irregular lump which fails to flatten out under the hand. This area, Delbet says, is carcinomatous. Even the simple solitary cyst seems to receive the same rather drastic treatment as the areas of simple mastitis. So long as the excision is drastic enough de Frenelle thinks that its exact nature can be left to the judgment of the individual

<sup>1</sup> *Technique Chirurg.*, April, 1936, p. 81.

<sup>2</sup> Delbet, P., et Mardene: *Les Cancers du Sein*.

surgeon. He is in favour of avoiding disfigurement as far as may be, and he believes that it is possible to remove the whole gland except the nipple by a single curved incision, and still leave the patient without an unsightly deformity. The axillary pedicle is removed in every case. It is perhaps a little difficult to be convinced about the case he quotes of metastases in the axilla with a perfectly innocent appearance in the breast itself. Nothing short of a complete slicing of the whole breast is satisfactory in these cases, and there is no account of such an examination. The reason that de Frenelle was so impressed by this particular case was that he had at first deferred operation because of the negative clinical findings. One of the most anxious decisions that a surgeon has to make is whether or not to operate on a patient who presents herself with an apparently innocent lump in the breast. De Frenelle has certainly simplified matters by his advice to operate every time. Judging by recent discussions he will find many to disagree with him.

### THE BASIS OF FOGGINESS

THE Faraday Society met at Leeds on April 20th to discuss disperse systems in gases, that is to say, the minute liquid drops and solid particles distributed in the atmosphere and resulting in smoke, cloud, or fog. The colour of some of the buildings in that city made it an appropriate locus for the study of dispersed carbon, and in fact Leeds University chemical laboratory is well known throughout the world for the researches of Prof. R. W. Whytlaw-Gray, F.R.S., and his school on artificially produced smokes. The subject attracted authorities from all over Europe to join in a discussion which went on for three days. Prof. Hilding Köhler of Upsala expounded his theories on the Aitken nucleus, the minute association of hygroscopic molecules a few millionths of a centimetre in radius, which serves as a growing point for each of the droplets constituting cloud and fog, in supersaturated air becoming raindrops. In the pure air of the arctic circle, where he has worked, the nucleus is sea-salt. Our readers are mostly more concerned with the less pure air of inhabited regions. Mr. J. H. Coste, formerly chemist-in-chief to the London County Council, described the dispersoids which he and others have found in town and country air. In towns nitrous acid, ammonium salt, and free sulphuric acid may form nuclei, in addition to the sea-salt of pure air. Characteristic are the larger, but still very fine, solid dispersoids which can be concentrated by dust counters such as those of Owens or Whytlaw-Gray and Green, or estimated (in respect of their soot content) in the Owens filter; these include, besides soot, calcium sulphate and carbonate, fine silicious particles and probably other unidentified constituents. Coarser dispersoids are also met with, e.g., pollen, spores of fungi, moulds and ferns, bacteria, silicious matter—both actual sand and spheres of fusible silicates from industrial furnaces—with ash from domestic chimneys. In discussing this paper Sir Robert Robertson referred to researches in the Government laboratory on the combustion products from various heating appliances which included nitrous acid, the presence of which as Aitken nuclei had been demonstrated by Coste and Wright, whilst Dr. R. Meldau of Charlottenburg recalled Ehrenberg's remarkable discovery in the air of Berlin, among many other unexpected substances, of pollen from Australian plants. Prof. J. Firket of Liège set out the circumstances which led to the disaster of December, 1930, in the Meuse

valley, when several hundred inhabitants were attacked with respiratory troubles, 63 of them ending fatally, whilst many head of cattle had to be slaughtered, as the result of an intense and irritant fog lasting some days. The Royal Commission, of which Firket was a member, attributed, on circumstantial evidence, the symptoms to an accumulation of sulphur dioxide and sulphuric acid produced by combustion of fuel in the many factories of the highly industrialised Meuse valley, a finding which Mr. Coste was inclined to agree with, in view of the high concentration of sulphur dioxide found in London air for short periods during the darkest period of the fog of Dec. 23rd, 1935, when very deep stains were obtained in the Owens filter. He and Mr. G. B. Courtier had found sulphuric acid increased in London air during fog. The industrial aspects of disperse systems in air and gases were introduced by Mr. R. Lessing, Ph.D., who referred to the gas-cleaning systems in use at Battersea and Swansea and in prospect at Fulham; Mr. Nonherbel described the I.C.I. plant for removal of smoke and oxides of sulphur from flue gases. A suggestive communication was that of Prof. D. Brunt on the local dissipation of fog for the sake of aviators wishing to land at an aerodrome in foggy weather, and who would be greatly helped if a small area could be rendered fogless for even a very short space of time. The discussion will be reported in full in the transactions of the Faraday Society to appear early in August.

### THE TRAFFIC IN DANGEROUS DRUGS

AT a recent meeting of the Permanent Central Opium Board at Geneva Mr. Lyall, the British representative, was re-elected chairman and Mr. May, the American representative, vice-chairman. The latter was also appointed a member of the supervisory body set up under the Limitation of Manufacture Convention of 1931. It is important that the three organisations established by the League of Nations to deal with different aspects, and from different points of view, with the traffic in narcotic drugs should be kept in close touch. These are the advisory committee on opium which dates from the early days of the League, the Permanent Central Opium Board under the Convention of 1925, and the supervisory body which determines the estimates of the several drugs required by various countries for medicinal purposes. The Board learnt with satisfaction that the Union of Soviet Socialist Republics had ratified the Opium Conventions, and urged those Governments which had not yet adhered to proceed to do so. The Peruvian government had announced its inability to control or supervise the production of coca leaves, but was proceeding to regulate the manufacture of crude cocaine.

Certain discrepancies shown between import and export statistics of dangerous drugs engaged the attention of the Board, notably those of consignments of raw opium from Turkey to Japanese territories. Explanations were also vouchsafed from the Swedish, French, and Bulgarian Governments concerning their manufacture of drugs in excess of the estimates furnished by them for 1934. While the Board feels itself in a position to report to the Council of the League that the amount of drugs now manufactured from both opium and coca leaves for legitimate consumption is lower than the estimates made in 1931, it nevertheless directs attention to the danger arising from the fact that more opium is grown in the world than can be legitimately consumed. Attention is called to the large number of

drug addicts in the United States and Canada, although the control of manufacture is very strict, and the conclusion is drawn that the present system of fighting the illicit traffic is ineffective, fostered as this traffic is by clandestine factories annually producing many tons of the drugs. A conference on its suppression will be held in Geneva on June 8th.

### BRITISH NEUROLOGISTS IN HOLLAND

A MOST successful development of international relations in neurology took place last week-end, when a party of twenty representative neurologists, under the ad hoc presidency of Prof. Edwin Bramwell, visited Holland. A conjoined meeting was held there of the section of neurology of the Royal Society of Medicine and the Amsterdam Society of Neurology. The president of the latter, Dr. de Jong, and the secretary, Dr. Tammemons Bakker, arranged an instructive programme at Prof. Brouwer's clinic within the Wilhelmina-Gasthuis. The Friday morning session was spent in a visit to the wards and laboratories of the neurological department where selected cases were demonstrated. Short papers were read in the afternoon by members of the Dutch society, and in the evening the English visitors were entertained to dinner by private hospitality. Saturday morning was devoted to a visit to the psychiatric clinic of Prof. K. H. Bouman and to demonstrations of experimental psychology (Dr. van der Waals) and of neurophysiology (Dr. de Jong); and visitors were privileged to see Dr. Oljenick, the Amsterdam neurosurgeon, operating upon a case which had been shown the day previous by Prof. Brouwer. A dinner, followed by a reception, was held at the house of Prof. and Mrs. Brouwer in the evening. This valuable and informative combined meeting was concluded on the Sunday by a motor coach tour of the bulb-fields near Haarlem with a visit to a tulip farm.

### HEALTH IN PRISONS

COMPILED in relation to the year 1934, the recently issued annual report<sup>1</sup> of the Commissioners of Prisons has interesting notes on the changes visible in the past 25 years. Cirrhosis of the liver is now less frequent, acute gout in the big toe-joint is seldom seen, delirium tremens is absent, and states of mind attributable to alcoholism (constant causes of admission to the prison hospital in pre-war days) are comparatively unusual to-day. Among young women chlorotic anæmia, formerly common, has almost disappeared, and, thanks to the fashion of wearing the hair short, verminous heads are few. Dr. W. Norwood East, the medical commissioner who marshals these facts, notes on the other hand an apparent increase in minor mental illness, and thinks this is not due merely to the more vigilant recognition of symptoms. Prisoners to-day, he believes, are of a higher standard of intelligence. Harsh punitive measures are no longer employed. Separate confinement has been abolished. There is a weekly news reading, there are debates, lectures, concerts, and library books. Physical training has been introduced in place of the monotonous exercise of walking round in a ring. The close crop ceased in 1922, and soon afterwards shaving in prisons became general, prisoners being allowed to shave themselves or be shaved, and in many cases to have their own safety razors and brushes. The broad arrow has disappeared from convicts' clothing; prisoners who have escaped are no longer obliged to wear parti-

coloured clothes or carry leg chains. And yet, remarks the medical commissioner, prisoners in general are remarkably conservative in their outlook; the old hands prefer the narrow and rigid discipline of former times. The older generation, he says, have fewer interests, fewer requirements, and less need for outer contacts, while the younger generation is less self-reliant, more indulgent in self-pity, and less comfortable under the restrictions of a penal institution or in facing re-entry into civil life. The old heavy sentences are said to have induced insubordination and the assumption of bodily and mental disability. Malingering to-day is thought to be less common than formerly and, when it occurs, to be often the result of self-compassion. The general health in our prisons continues to be good. Five prisons are now equipped for the performance of major surgical operations.

It is a pity that these annual reports of the prison commissioners cannot be more promptly issued. The year 1934 is now ancient history, and the sense of perspective is distorted by references to subsequent events—such as the Money Payments (Justices' Procedure) Act, 1935, which came into force this year.

### EXPERIMENTAL GLOMERULO-NEPHRITIS

FAILURE to reproduce the histological picture in animals has been a baffling feature of research on Bright's disease, and it is a failure that is surprising when we consider the strong evidence that infection causes the disease in man—witness the renal sequelæ of tonsillitis and scarlet fever and the frequent association of diffuse glomerulo-nephritis with sub-acute progressive endocarditis. In these instances the streptococcus is more frequently isolated than other organisms. But the considerable interval that often elapses between the onset of the infection and the onset of the nephritis seems to show that the mechanism is not a perfectly simple one. The theory that the inflammation of the kidneys is an allergic manifestation has been advanced to explain the facts, and has gained support from work during the past three years in Fahr's laboratories in Hamburg where Masugi and others have succeeded in producing a glomerulo-nephritis in rats by injecting into them serum from rabbits treated with a series of injections of a suspension of rat's kidneys. The similarity of this nephritis to Bright's disease in man encouraged Arnott, Kellar, and Matthew to repeat the experiments, and they now report<sup>1</sup> that they have similarly produced a diffuse glomerulo-nephritis in rabbits by injections of serum from ducks subjected to injections of a suspension of rabbit's kidneys. The resemblance, as far as the glomeruli are concerned, was more impressive in the animals which lived longer than a fortnight than in those dying within a few days. The former showed an increase of endothelial nuclei in the tufts, adhesions of the tuft to the wall of Bowman's capsule, and epithelial crescents; these are the diagnostic histological features of Bright's disease in man. It is also of interest that, in the one example in which blood-pressure readings were obtained by the carotid loop method, a sustained rise of about 30 mm. was recorded. A control series of rabbits injected with normal unimmunised duck serum showed no nephritis.

This experimental nephritis, which seems attributable to an intense antigen-antibody reaction in the rabbit, suggests that Bright's disease in man is likewise

<sup>1</sup> H.M. Stationery Office, Cmd. 5153. 2s.

<sup>1</sup> Arnott, W. M., Kellar, R. J., and Matthew, G. D.: *Edin. Med. Jour.*, April, 1936, p. 233.

the result of an intense antigen-antibody reaction in a patient with streptococcal infection. The implications of this preliminary report are so important that those interested in the pathology of Bright's disease will doubtless hope for an opportunity of examining the authors' preparations.

### RECORDS, MERRY AND TRAGICAL

DUKE THESEUS pronounced the story, a dramatic version of which he was afterwards to witness by the famous Bottom troupe, as "merry and tragical" and records of medieval medicine produce just these emotions. While we are filled with admiration for the learning and industry of the authors, their ingenuity in finding reasons for preposterous therapeutics cannot fail to amuse, while it is tragic to observe how many lives could have been saved if credulity had not so often got ahead of reason. The writings of Johannes de Mirfeld, translations from which have just appeared made by Sir Percival Horton-Smith Hartley and Mr. Aldridge,<sup>1</sup> are indeed merry and tragical, and fill a gap in the knowledge of most of us. There is in Norman Moore's "History of St. Bartholomew's Hospital" considerable reference to Mirfeld, showing him to have been a deeply learned man, but the story as presented was imperfect—only a sketch was intended—and it is well that we should have fuller information of the life and works of an important scholar. His two books are entitled the "Breviarium Bartholomei" and the "Florarium Bartholomei," and each proves that their author had read the works of Gaddesden, Galen, Rhazes, and Avicenna, while he knew the precepts of the school of Salerno, where Jewish and Arabian wisdom was blended with classic precept. His biography, as set out by the authors, is very detailed, the result of elaborate research for which they deserve warm credit. The various charters, rolls, and diocesan and parochial records which have been consulted by them must have been difficult to decipher, and when deciphered equally difficult to comprehend exactly, for in many places the sequence had been sadly disturbed in the course of six centuries by the loss of connecting documents. Exactly what standing as doctor or priest Mirfeld had in connexion with St. Bartholomew's is not easy to define. He was a clerk of the Priory of St. Bartholomew's, and although the priory and the hospital were distinct institutions he was evidently in close touch with the medical side, as proved by literary work and by the fact that after ordination as priest he derived his subsistence not from the priory but from the hospital. What comes out, however, from authentic history and from internal evidence is that he was a devout and learned man who had the fine resolve to compile all the medical knowledge of the world up to his date, and to perform the task for the sake of humanity and to the Glory of God—sentiments which he frequently reiterated and whose sincerity his manuscripts prove.

The Breviarium represents the medical learning of the fourteenth century. The work exists in several versions as a manuscript, and if printed in full would cover some 2000 pages of an octavo volume. From this great store the authors have selected for translation the chapter on the signs of fatal illness and

the chapter on phthisis. Their choice was decided because the "De Signis Malis" is the most general essay in the immense treatise and deals with an aspect common to many diseases—namely, death. The chapter "De Ptisi" was chosen because the authors were personally interested in all relating to the disease which, it is suggested, may have contributed to the cause of the death of the Black Prince, Mirfeld's contemporary. Both chapters give us a fine opportunity of comparing the standard of scientific knowledge reached in the Middle Ages with that enjoyed since the discovery by Harvey of the circulation of the blood; indeed long after Harvey had supplied a physiological basis for medicine, practitioners clung to the tenets observed through over 2000 years. Mirfeld made no pretence to originality, and the Breviarium is largely compiled from the works of classical and Arabian medicine. He displays little or no systematic medical knowledge, theories seldom, and is mainly interested in the extraordinary remedies which he puts forward on various authority. The Florarium is a theological work which survives only in imperfect manuscripts, and but one of its 175 chapters deals with physicians and medical treatment. Here Mirfeld is not complimentary to the profession, but, as the authors point out, the chapter indicates such general advice for the maintenance of health as would be given by a physician living at the end of the fourteenth century, while it illustrates the theories on which medical treatment at St. Bartholomew's hospital would have been based up to Mirfeld's day and for some time subsequently. In the Florarium as throughout the Breviarium we have examples of the wild superstitions which led to the employment of complicated remedies for application or digestion in all sorts of conditions, from the obviously fatal to the obviously trivial. We forget the misery that attended such therapeutics in our amused wonder that real learning, of which there was often much, should be blended with such comic credulity. The authors are to be thanked for a very acceptable book.

### RECOVERY AFTER CHILDBIRTH

WRITING in the *Times* of April 27th Dr. Gordon Ward draws attention to the frequent mention in the new Midwives' Bill of ten days as the period that should normally elapse between childbirth and the last visit of the nurse. He goes on to suggest that sanction of the ten-days standard by the Minister of Health will mean that thousands of mothers—tired, undernourished, and suffering from repeated labours—will be led to believe that the eleventh day should find them sufficiently recovered in health to return to their full duties as mother of a family. This protest was repeatedly endorsed in the second-reading debate on the Bill (see p. 1090). The assumption that the midwife's duties are discharged ten days after a normal confinement has for many years been regarded by the medical profession as thoroughly unsound. The responsibility for it rests it seems on the Central Midwives Board, for ten days has always been given in their rules as the statutory nursing period in a so-called normal case. It is natural enough that an administrative body such as the Ministry of Health should follow this lead, on the presumption that the Central Midwives Board would not have made such a ruling without careful consideration. But the result is that an obviously dangerous principle finds expression in the new Bill. As Dr. Gordon Ward says, the one safe standard is the medical standard: the midwife

<sup>1</sup> Johannes de Mirfeld, of St. Bartholomew's, Smithfield. His Life and Works. By Sir Percival Horton-Smith Hartley, C.V.O., M.A., M.D., F.R.C.P., Consulting Physician to St. Bartholomew's Hospital and to the Brompton Hospital; and Harold Richard Aldridge, M.A., Assistant Keeper in the Department of Manuscripts in the British Museum. London: Cambridge University Press. 1936. Pp. 191, 158.

should remain in attendance, and the mother should remain in bed, until she has fully regained her strength—regardless of normality in pulse, temperature, or involution. The time required for recovery will necessarily vary with circumstances, responsibilities, stamina, and general health, and we agree with Dr. Ward that before discharging herself from her case, the midwife should report to a doctor who must assume further responsibility. The introduction of any time-factor into obstetrics, whether for pregnancy or labour, can only be deplorable.

#### MEDICAL INSURANCE AGENCY

THE annual general meeting of the M.I.A. was held on Wednesday of last week when Sir Humphry Rolleston from the chair was able to report continued progress. The agency was established in the interests of medical practitioners to ensure that they received expert advice and assistance in obtaining contracts suited to their own particular needs, and the rebates accruing have resulted since the start of the Agency in the direct saving to members of the medical profession of over £70,000, while through the same period over £40,000 have now been distributed to recognised medical charities.

The charitable grants approved on April 29th were as follows:—

	£	s.	d.
Royal Medical Benevolent Fund—			
Under deed of agreement .. .. .	1260	0	0
For general purposes .. .. .	250	0	0
Special centenary appeal .. .. .	250	0	0
Ladies Guild of the R.M.B.F. .. .. .	620	0	0
Royal Medical Foundation of Epsom College—			
For general benevolent purposes .. .. .	315	0	0
Sherman Bigg Fund—to be used as necessary .. .. .	200	0	0
Grant for special case .. .. .	105	13	3
Girls Education Subcommittee .. .. .	300	0	0
Sir Charles Hastings Fund .. .. .	450	0	0
Royal Home for Incurables, Putney .. .. .	52	10	0
	£3803	3	3

Proposals for insurance to the number of 387 were received during the year, totalling a sum of over £500,000; of these 334, totalling sums assured of £446,947, were completed. During the year 215 policies were negotiated, approximating to £470,000 of maximum "Family Protection" cover, which to date brings the sum so completed to over three million pounds, represented by some 1500 policies. Considerable progress may be noted in the interim report respecting motor-car insurance, and difficult of settlement as many of these cases have been there is evidence of much gratitude from the supporters of the Agency for equitable arrangements. Certain loans have been made for the purchase of medical practices through the medium of the Caledonian Insurance Company, The Clerical Medical and General Life Assurance Society, and the Century Insurance Company, and it is noted that there is a growing tendency for the purchase price of practices to be enhanced, a feature which is particularly conspicuous in the London area. In the balance sheet the audited accounts show increases in the premium income. The whole story is one of progress.

WE regret to record the death of Dr. Th. E. Hess Thaysen of Copenhagen, a physician well known in this country for his original observations on metabolic diseases. He was the first to record, in 1926, the low sugar-tolerance curve of idiopathic steatorrhœa, and his monograph on "Gee's Sygdom, the Cœliac Affection," published in 1931, was a valuable work

which has had interesting repercussions, though his term "non-tropical sprue," for cœliac disease in adults, is not generally accepted. Among his writings many of our readers will most readily recall the paper on "proctalgia fugax" contributed to our columns last August. Subsequent correspondence showed that this condition had often been observed by others, but it had been left to Thaysen, with his clinical insight, to paint the picture and give it a name. The charm of his writing reflected his personality, and many of his English colleagues had reason to think kindly of him.

ON Monday, May 11th, at 8.30 P.M., Sir James Walton will deliver the annual oration of the Medical Society of London. He will speak on carcinoma of the stomach, and the address will be followed by a conversazione.

ON Tuesday, May 19th, at 4.15 P.M., at St. Mary's Hospitals, Manchester, Dr. Walter Schiller, pathologist to the University Frauenklinik in Vienna, will give the Lloyd Roberts lecture on cancer of the uterus. On Wednesday and Friday, May 20th and 22nd, at 4 P.M., he will deliver the Ingleby lectures at the University of Birmingham, when he will speak on granulosa-cell and Brenner tumours of the ovary and on "mesonephroma ovarii."

Sir Herbert Austin has given £250,000 for the extension and further endowment of the Cavendish Laboratory of the University of Cambridge. Lord Rutherford has announced that the first use made of the money will be to build a laboratory for the utilisation of very high voltages in order to carry out experiments on the transmutation of matter by high-speed particles and by radiation. This is the greatest single benefaction the university has ever received, and it is intended as a tribute to the work of J. J. Thomson, Rutherford, and their associates.

THE sixth International Congress of Physical Medicine opens on Tuesday next at the Hotel Great Central, London, under the presidency of Sir Robert Stanton Woods. The proceedings, which will include meetings at the Royal Society of Medicine and the British Institute of Radiology, will be grouped under the headings of kinesitherapy, physical education, hydrotherapy and climatotherapy, electrotherapy, actinotherapy, radiology, and the teaching and organisation of physical medicine in schools and universities. Visits will be paid to hospitals and clinics, and there will be tours in the neighbourhood of London and to spas. Further particulars may be had from the hon. secretary, Dr. Albert Eidinow, 4, Upper Wimpole-street, W.1.

WE regret to learn the death of Mr. David M. Greig, Conservator of the Museum of the Royal College of Surgeons of Edinburgh, which occurred at Edinburgh on May 4th.

Mr. A. J. Melly, F.R.C.S. Edin., who initiated, organised, and led the British Red Cross ambulance unit in Abyssinia, was wounded in the right lung by a revolver shot on the morning of May 3rd, when he stopped his car to pick up a wounded Ethiopian. As we go to press we learn that he died on May 5th at the British Legation at Addis Ababa.

ALBERT DOCK HOSPITAL, LONDON.—A further £30,000 is needed to complete the £75,000 required to rebuild this hospital which will then include one of the best equipped fracture clinics in the United Kingdom.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### XCIX.—PROGNOSIS IN ARTHRITIS

(Concluded from p. 1025)

#### Osteo-arthritis

THE classification adopted by the British Medical Association committee divided osteo-arthritis into primary and secondary forms.

*Primary osteo-arthritis*, of which Heberden's nodes furnish a typical example, is due to degenerative changes arising from excessive wear and tear such as may characterise certain occupations; probably deficient blood-supply, the result of arterio-sclerosis, favours such changes; it is insidious in onset and before treatment is sought the joint cartilage may be almost destroyed and extensive osteophyte formation may have taken place. This is very liable to occur in the hip-joint and though the damage cannot be undone careful treatment will prevent the joint from becoming fixed in a bad position. The pain and difficulty of walking leads the patient to sit for long periods and the joint may become fixed in a flexed position; this may be overlooked in its early stages, since it is remarkable how far the hyperextension of the lumbar spine can compensate for flexion of the hip-joint. Radiographic examination is desirable and both hip-joints should be included for the additional strain thrown on the apparently sound side may soon set up arthritis there also. A well-fitting calliper splint is most useful in facilitating exercise, relieving the strain in the sound joint, and often also relieving pain which may otherwise be so severe in the damaged joint as to render walking impossible. A point of much importance in the early recognition of this disease, and thus in improving prognosis by proper treatment, is that at first the pain may be referred often to the knee-joint as in tuberculous disease of the hip in children; it may also be referred to the adductor region or to the area of distribution of the sciatic nerve. Much time may be lost in futile treatment of a painful knee showing no objective signs except perhaps a little crepitus when a radiographic examination of the hip would reveal the true cause of the symptoms. A radiogram may, however, reveal the presence of small osteophytes which are not of importance in themselves, being compensatory to ligamentous strain. They are often seen at the margins of the knee-joint and especially at the upper edge of the patella; but in the absence of evidence of any serious damage to the cartilage they are not of any serious moment from the point of view of prognosis. In the hip, however, similar appearances are of importance owing to the anatomical characters of that joint.

*Secondary osteo-arthritis*, the sequel of gout or of rheumatoid arthritis which has been successfully treated or has burnt itself out, must be recognised as a process of repair, but may call for splinting or other support to control or prevent deformity and thus improve the prognosis and help to make a more active existence possible.

#### PROGNOSIS AS REGARDS MOBILITY

The range of mobility retained by patients with osteo-arthritis will depend on how early treatment is begun. If this has been neglected, restriction of range of movement may result in consequence of contraction of the capsule from peri-articular fibrositis, or from the presence of osteophytes in such a position

as to interfere with normal movement. Bony ankylosis does not occur. The same principles both of prevention and treatment will apply as in rheumatoid arthritis, but the hip-joint is the one which most frequently gives rise to difficulty and restriction of movement. The use of a calliper walking splint hinged at the knee will often relieve pain and if fitted so as to secure a slight degree of extension it will lessen the wear and tear on the articular cartilage and permit of some degree of repair. If there is already some restriction of play in the joint, which is most common in the direction of flexion or adduction, movement under an anæsthetic should be attempted and followed by fitting of a calliper walking splint. In my opinion open operation is rarely justified and only for the relief of severe pain or malposition which cannot otherwise be overcome. Excision of the head of the femur will leave a weak and often useless limb, while a fixed joint, the result of arthrodesis, is a prospect which most patients will prefer to avoid even at the cost of pain.

#### SPONDYLITIS

In this condition it is of the utmost importance to distinguish the two principal forms.

*Ankylosing spondylitis*, which has much in common with rheumatoid arthritis, may speedily, if not recognised, give rise to severe and irreparable crippling; this is the form called "spondylose rhizomelique" by the older writers. It is a disease of young adults, insidious in onset, often with pains in the limbs for months before it becomes obvious that the vertebral column is the real seat of the mischief, and by this time the sacro-iliac joints and the joints between the articular processes of the lumbar vertebrae are often seriously damaged or even ankylosed. In most cases the lumbar spine is first affected, but in a few it begins in the cervical region. Rest and treatment on the lines already indicated will make all the difference to the prognosis both as regards the progress of the disease and the nature and development of deformity. It is of great importance to carry out systematic respiratory exercises as the costovertebral joints are affected early and if care is not taken the thorax quickly becomes a rigid cage. Care must also be taken to prevent or, it may be, to correct any tendency to bad position in the vertebral column in which some degree of ankylosis is practically unavoidable. The hip-joints are usually attacked very early in the course of the disease and may soon be immobilised; the shoulders are affected much later.

The tendency to remission is more marked in ankylosing spondylitis than in other forms of arthritis, which is a fortunate thing, since there is no specific method of treatment known at present, and we can only depend on rest and building up resistance to the invasion, whether it be a streptococcus or a virus or any other cause. If care has been taken to secure a good posture the activity of the patient when the stage of remission is reached is often remarkable, and a degree of movement in the joints is regained which the X ray appearances would lead one to regard as impossible. Care in treatment on the lines already indicated, especially in securing an ample intake of calcium-containing food together with adequate vitamin D, may prevent any recrudescence of symptoms and cure may thus result.

It must be remembered that the latent period may last for years and then the symptoms reappear and extend till the spinal column is a rigid bar, the ribs immovable, and often the shoulders and knees ankylosed. Other joints may be affected, especially the mandibular, so that it becomes impossible to separate the jaws. Even in most advanced cases with complete rigidity of the spine, often in so distorted a shape that the unfortunate patient can neither stand, sit, nor lie in any degree of comfort, compression of the spinal cord or of the spinal nerve-roots is rare.

The second form of spondylitis is *osteo-arthritis of the vertebral column*. It is common in men who have led an active laborious life; in fact, it is rarely that some evidence of the condition is not to be seen in radiograms of working men or women who are getting on in years. It is of importance to remember this, for such appearances, which may cause alarm, are of no serious import. They were recognised by Sir Samuel Wilks who gave the name "the labourer's spine" to the condition. It is characterised by increased stiffness, never going on to ankylosis, though adjacent osteophytes may unite to form bridges between the vertebræ. Pain is not a prominent symptom unless, as sometimes occurs, the nerve-roots are pressed upon by osteophytes in the spinal canal or at the point of emergence from the foramina. The prognosis is, therefore, favourable; life is not threatened and activity not seriously limited, but the working man may be obliged to give up his work because of chronic, though not severe, pain in the back made worse by stooping or lifting. The contrast with ankylosing spondylitis in prognosis is so great that it is of the utmost importance not to confuse the conditions.

### Spa Treatment

Spa treatment is of much assistance in the later stages of rheumatoid and in osteo-arthritis. Specialised methods of applying heat by peat or mud packs combined with hot douching give great relief, while the manipulations which are a feature of the deep pool bath often increase the range of movement surprisingly. Many patients of the poorest classes, for whom the spa hospitals exist, find a course of treatment once or twice a year serves to keep them going in reasonable comfort. In the more acute forms of rheumatoid arthritis the patient is better at home unless the conditions are such that a hospital or clinic at a spa or elsewhere is to be preferred. Among those preferably treated away from home are women who cannot otherwise obtain the rest and freedom from household cares which is essential. The orthodox cure of limited duration with residence in a hotel or lodgings will be of little service in these cases. It is a question of nursing-home or hospital.

The full value of spa treatment will only be obtained if in principle it is continued after the patient has returned home; and he should be instructed how to carry out simple forms of treatment along definite prescribed lines. A relative can often be taught to massage the limbs (with a warning not to rub the joints except in the gentlest manner), to help in carrying out resisted movements and exercises for re-educating muscles, and to use simple forms of heat treatment. Ample information as to suitable spas will be found in the handbook issued by the British Health Resorts Association.

C. W. BUCKLEY, M.D., F.R.C.P.,

Hon. Physician, Devonshire Royal Hospital, Buxton,  
and to the Buxton Clinic for Rheumatic Diseases.

## SPECIAL ARTICLES

### MEDICINE AND THE LAW

#### Delinquency as an Ailment

At the South-Western police-court last month the metropolitan magistrate remanded an accused man for a month in order to obtain a report about him from the Institute for the Scientific Treatment of Delinquency. The magistrate was Mr. Claud Mullins, whose zeal as a reformer of legal procedure has been shown both in his court and in his writings. He is by no means the first member of his body to have recourse to the psychologist; the late William Clarke Hall incurred the ridicule of old-fashioned legal critics for the psychiatric "circus" which was said to attend his court. The step now taken by Mr. Mullins, however, probably indicates that the bench is now prepared to take advantage of modern psychotherapy. The accused man, aged 34, was charged with a serious offence of indecency towards a child. His medical history, as stated to the court by the defending advocate, included sleepy sickness in 1919, cerebral meningitis and double pneumonia in 1922, and a severe scalp wound in 1927; he was said to have been unconscious for months in Martinique when suffering from some obscure form of disease. The police witnesses, who regarded him merely as a pest to the public, outlined his previous convictions and remarked that he seemed always to get into trouble in the month of April. Mr. Mullins pointed out that the man had at first pleaded "not guilty" and had thereby given consider-

able trouble in eliciting the facts; afterwards he pleaded "guilty." The maximum sentence was six months' imprisonment, but this would leave the man at large next April to be again a danger to the public. It was not possible to treat him as "guilty but insane"; the magistrate therefore thought it the best course to send the case for investigation to the institute already mentioned. Needless to say, the magistrate has no power to order a man to be thus dealt with; the man goes to the institute of his own free will. Alteration of the law, to enable persons on remand to be compelled to attend a clinic for examination, has been felt desirable by prison visiting justices and others. Our penal institutions are not adequately equipped to accommodate patients for this purpose.

Psychological examination before sentence is more novel than the psychological treatment in penal establishments which was recommended by the Persistent Offenders Committee some years ago. The recently issued report of the Commissioners of Prisons for the year 1934, referred to specifically on another page, contains a cautious statement by Dr. W. Norwood East on the progress made. This committee considered that a certain amount of persistent crime was due to abnormal mental factors, that the usual punitive and reformatory methods in cases outside the scope of the Lunacy and Mental Deficiency Acts often failed, and that there was reason to think that in selected cases delinquents might be amenable to psychological treatment. Dr. W. H. de B. Hubert was accordingly appointed to Wormwood Scrubs Prison as psychotherapist.

Dr. East observes that, as expected, some prisoners apply for this treatment out of curiosity, others in the hope of preferential conditions while in custody, while others again are genuinely anxious to be relieved from their disability. He adds a warning that a few law-breakers are believed to be exploiting the medical psychologist, attending psychotherapeutic clinics, and equipping themselves in advance with evidence to show that, being under treatment, they are irresponsible or, at any rate, fit subjects for leniency. "It cannot be urged too strongly," Dr. East concludes, "that dishonest intentions on the part of accused persons should be exposed, and unqualified practitioners denied the opportunity of bringing into disrepute a method of treatment which may prove to be of value." When this fraudulent element is eliminated, the community must be patient with the new methods. Quick results must not be overconfidently claimed; care is needed to follow up the released prisoner and to test success over a long period. Ordinary psychological investigation has sufficed to restore normal mentality in many cases of attempted suicide. In other groups of offences prolonged and intensive treatment can secure readjustment. There remains a class of offenders who do not respond at all. The difficulty is to identify the curable, to prove the genuineness of the desire to be rid of the pathological state which is linked with the anti-social conduct, and to establish the successes while taking note of the failures. The legal and judicial attitude towards offenders, and indeed the attitude of the public as a whole, will not be moved by mere enthusiastic insistence that all crime is a disease. It can be demonstrated that some crime at any rate is attributable to neurosis. Progress will be easier when results are at length visible. Dr. East in his recent report says he has no doubt that the professions of law and medicine are drawing nearer in regard to questions of crime and insanity.

#### Criticisms of a Surrey Remand Home

The *Surrey Comet* publishes some disquieting criticisms of a remand home administered by the county council. The complainant is the father of a boy, aged 13, who was remanded in a case where eight lads had been charged with damage to an occupied house. The home, he says, is a gloomy villa with heavily barred windows. It accommodates ten boys in one fair-sized living-room divided by a partition. Their ages range from 9 to 17 years, and they are locked up in these rooms from 7.30 A.M. to 8.30 P.M. every day. The only outdoor exercise allowed is about 30 minutes in the morning and evening in a small yard 10 feet square surrounded by a corrugated iron wall with barbed wire and spikes. There are two bedrooms, six beds in one and four in the other. The toilet arrangements consist of one bath: all ten boys wash in the same water; there are no hand bowls or other utensils. The superintendent, while anxious to do the best he can, has another post as caretaker of an elementary school.

"Remand homes" have taken the place of the "places of detention" provided under Section 108 of the Children Act (now repealed). County councils and county boroughs must provide them, but need not provide additional ones so long as the old places of detention remain suitable for use and are sufficient for the needs of the area. The recent criticisms will no doubt be carefully investigated. Temporary residence under the alleged conditions might well be an unsettling experience for the young.

## UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

### SYPHILIS

UNDER the leadership of Surgeon-General Cumming a very liberal policy has been pursued by the U.S. Public Health Service in its relations with the several State health administrations. Advice and help have been freely granted on request. No attempts at regimentation have been made. When the State and territorial health officers gathered at Washington on April 13th the new surgeon-general, Dr. Thomas Parran, Jun., made it quite clear that this policy will be continued. If, said he, one State finds pellagra its chief problem and wishes to spend three-quarters of its funds fighting pellagra that is perfectly all right with the federal service. Dr. Parran's own conviction that syphilis is a major, perhaps the major, public health problem in this country may have been deduced from the distinguished galaxy of clinicians and epidemiologists who read papers on syphilis on the first day of the conference. Dr. Earle Moore, syphilologist in the Johns Hopkins medical school, emphasised the amount of syphilis that exists in people who are unaware that they may be infected. One man in five, one woman in three acquires the disease without knowing it. Thirteen years ago he showed that 5000 syphilitics passed through Johns Hopkins annually unrecognised. Only in the last six months has his hospital adopted a routine Wassermann test for all patients. If this procedure were adopted by all hospitals in the country 700,000 new cases of syphilis could be discovered annually. If in addition the test were also applied in out-patient departments another million new cases would be discovered. Dr. Moore urged the establishment of free clinics whose presence, far from interfering with private practice, is found, he said, to increase the demand for treatment from the private practitioner.

Dr. Dudley Smith described epidemiological studies made in connexion with the syphilis clinic of the University of Virginia. Questioning of 207 cases had resulted in knowledge of 511 sexual contacts. Elimination of duplicates among these sexual partners reduced the number to 421. Of these 171 were persuaded to attend the clinic. The remainder were advised to consult a physician, with what success is not known. Seventy-four per cent. of the contacts who came to the clinic for examination were found to be infected. From these figures Dr. Smith calculates that each new case of syphilis gives rise to 1.5 new infections which clearly represents an increasing infection-rate. Lantern slides were shown demonstrating how from epidemiological study of the sexual contacts of a single case a small epidemic of syphilis could frequently be uncovered. The physician who makes the inquiry regarding contacts has at the same time a valuable opportunity to emphasise the importance of early and adequate treatment.

Dr. Stokes of Philadelphia spoke both eloquently and wittily of the educational methods available for arousing the interest of the profession and of the public in this subject. Doctors must not resent the acquisition by lay groups of special knowledge in this field. On the other hand, no progress can be made without the whole-hearted co-operation of physicians. The most effective education is learning by doing. Visual memory is more common than auditory memory, and printed propaganda, news stories, and feature stories are more effective than lectures.

Medical students in the University of Pennsylvania are not taught to be experts in dark-field examination or in serology. They are taught to take the specimens for such examinations and to expect that public health agencies will supply the necessary experts.

#### THE SERVICE AND NEW LEGISLATION

Two official dinners were given at the Congress. The first was a farewell dinner to Dr. Hugh Cumming to whom a certificate of life membership in the conference was presented by the dean of State health officers, Dr. Harper of Wisconsin. At this dinner Dr. Parran divulged a secret which had been known to himself only for a short time—namely, that he was a blood relation of Dr. Cumming through their maternal ancestry. On the second night a dinner was given by Miss Roche, assistant Secretary of the Treasury, at which brief speeches were made by Mr. Frank Bane, administrator of the Social Security Act, and by the new surgeon-general on the significance of the new Act. Dr. Parran pointed out very effectively that whereas other features of the Act spent larger quantities of money, and the money was well spent in alleviating the distress of old age, crippling, and unemployment, yet the relatively small amount of money devoted in the Act to public health is the only money that is spent in striking directly at the root of social insecurity and distress.

The two following days, April 15th and 16th, were spent in conference with the officials of the Children's Bureau, Department of Labor, in working out plans for the expenditure of federal subsidy for maternal and child care under the Security Act.

President Roosevelt received the delegates in his office in the White House at noon on April 14th. He spoke to them briefly but with his extraordinary personal charm and with a remarkably keen understanding of their essential problems. It is easy to believe, what his intimates tell us, that the President's most vital interest is the preservation of the nation's resources: vital and natural.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

#### THE PUBLIC HEALTH ESTIMATES

THE debate on the estimates of the Department of Local Government and Public Health was held recently in the Dáil, and the Minister was able to record advances in several lines of public health activity. There is now a whole-time medical officer of health in every county area, and systems of medical inspection of school-children have been widely established. Some 80 per cent. of the school-children come into the ambit of the schemes, although only one-fourth of these children were actually inspected during the year. The infant mortality has shown a decrease in both urban and rural areas. The death-rate among illegitimate infants is still abnormally high, being three and a half times that of legitimate infants. The Minister takes a special interest in housing and he was able to report much work in housing during the year. He stated that the question of more active work against tuberculosis was under consideration. In the debate which arose on the Minister's estimates, attention was mainly focused on the recent circular issued by his Department, in which local authorities were advised that the normal retiring age for their officers should be 65 and in some cases 60. Acting on this advice and

believing it to be mandatory, many local authorities have called on officers over 65 to retire. In reply to criticism in the debate the Minister repeated his assurance that the circular was advisory and not mandatory, and said further that, in his opinion, the local authorities would be acting illegally if they insisted on a general retirement at the age of 65. He also agreed that the case of medical officers required special consideration. The position created by this circular is peculiar and embarrassing. The wording of the circular, rather than its form, appeared to give it a mandatory character. Though the Minister has now declared that this was not his intention it does not appear that he has so far officially drawn the attention of the local authorities to the fact. It is admitted that there is a case to be argued as to the advisability of establishing a retiring age for the officers of local authorities, but if such a step is to be taken the whole system of salaries and pensions must be reconsidered, and the rights of existing officers must be safeguarded. The present position of the Department appears illogical.

#### THE DUBLIN HOSPITAL PROBLEM

The Hospitals Commission in its recent report recommended as its solution of the hospital problem in Dublin the enlargement of some and the amalgamation of others of the existing voluntary hospitals into four large general hospitals which would remain as voluntary hospitals. This solution was recommended by the Commission in opposition to a suggestion that had been made in favour of a large hospital under municipal control. It is understood that strong influences are at work in favour of the latter proposal, and, therefore, the discussion held by the Royal Academy of Medicine of Ireland on May 1st on the Dublin hospital problem was timely. A remarkably strong case for the development of the voluntary hospitals and in favour of the Commission's recommendation was made by several speakers—among others, Prof. Henry Moore, of University College, Profs. T. G. Moorhead and R. J. Rowlette, both of Trinity College, Mr. W. Doolin, and Dr. J. A. Harbison, medical officer of health for County Dublin—and a resolution was unanimously carried to that effect. The final decision rests with the Minister for Local Government and Public Health.

## INSTITUTE OF MEDICAL PSYCHOLOGY

At the annual meeting of the Institute held on Monday in the Wharnclyffe Rooms, London, the report for the year 1935 was presented by the medical director, Dr. J. R. REES, who welcomed the new members of the medical advisory board; their support, he said, would add further to the prestige of the Institute in the medical world. He described an attempt to clear off a long waiting-list by the appointment of four part-time medical officers to treat additional patients. In general hospitals a large proportion of routine clinical work is carried out by newly qualified doctors who give their services in return for the experience they gain, but this practice, he said, cannot be followed in psychotherapy which demands both maturity of outlook and specialist training upon a basis of general medical experience. Hence even the junior members of the Institute's staff are doctors of some seniority. The future efficiency of the Institute lay, he felt sure, in the adequate endowment of a sufficient number of part-time paid appointments to be held by psychotherapists of standing and experience with leisure to devote time to teaching and research. During the year a gratifying number of requests had been

received from other hospitals and clinics for names of psychotherapists trained at the Institute.

The report also contains an account by the newly appointed director of studies, Dr. J. A. HADFIELD, of the educational work done at the Institute. The five weeks' course for general practitioners has been attended by 39 doctors, 14 of whom enrolled for the year's training course designed for those proposing to take up the practice of psychotherapy. The full training course has now been extended to cover two years of study. The educational activities of the Institute are self-supporting. The salient feature of the report is the announcement of the acquisition of a new site for a central hospital and educational centre for psychological medicine, some further notice of which is given on another page.

Sir HENRY BRACKENBURY presided both at the meeting and at the luncheon which followed it, when he asked leave to emphasise one essential point. The Institute, he said, provides collective means for the use of psychotherapy and covers large lumps of ideas and methods. The staff does not confess to any particular school of thought. Prof. Wm. McDougall is a vice-president of the Institute; Dr. Alfred Adler was present both last year and this at their gathering; Prof. C. G. Jung had delivered a course of lectures during the year; and to-day with permission of his hearers he would send a telegram to Sigmund Freud, on the occasion of his 80th birthday, expressing their admiration of his pioneer work.

Sir KINGSLEY WOOD, Minister of Health, who then spoke, welcomed the opportunity of giving some account of the health services of this country as a whole. It was not so long, he said, since people regarded mental patients not as sick but as criminal. Now every year the activities of local authorities were getting more interesting as facilities became available for early treatment as a result of the momentum of the Mental Treatment Act, now five years in force. Last year 30 per cent. of admissions to mental hospitals were, he said, without certificate and he saw the beginning being made to secure preventive treatment. Behind there still lay a large borderland in which the Institute was playing its part. Dr. Halliday's significant figures from Scotland, analysing the 35 per thousand unfit for work, showed that in 30 per cent. of them incapacity was due to some form of mental illness. The larger premises into which the Institute was proposing to expand were a measure of its means and of its optimism. Two aspects of the situation, he thought, demanded special notice: (1) the opportunity offered by the Institute to general practitioners to see the early stages of nervous and mental illness successfully treated; (2) the opportunity for medical officers of mental hospitals to take refresher courses and so to mitigate the isolation of these hospitals. This was in line with the fundamental principle underlying the Medical Treatment Act.

Lord HOLLENDEN, speaking as treasurer of the Institute, sketched the enlargement of its work from the foundation of a clinic in 1920, in a private house in Tavistock-square, for the treatment of those disorders of mind not classed as insanity or mental deficiency. In 1931 the Institute moved into an adapted warehouse in Malet-place, and later became recognised by King Edward VII. Hospital Fund. Starting with 240 patients there were last year 1200, and 500 cases were dealt with a week by 70 doctors. The consultations could not be hurried, for sensitive patients required interviewing in separate rooms with the same doctor in attendance throughout. The continued increase in the work of the Institute was due, he felt sure, to the realisation of practitioners that the early treatment of the mental troubles that baffled them was carried out there with success. But finance was urgent; each interview cost 8s. 3½d., of which the patient's payment covered only a third. He must have the sympathetic understanding on the part of the whole business community whose problems the Institute was helping to solve. A quarter of their children came from L.C.C. sources,

but the L.C.C. gave them no grant. On the new site would be provided first of all a hostel for those who lived too far away to come up regularly for treatment. The site had cost over £68,000, raised partly on mortgage, partly on bank loan guaranteed by nine members of the council of the Institute. The hostel would cost £13,000, and the council would not start building until half of this money was in the bank.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. (retd.) T. Cock to rank of Surg. Capt. (retd.).

Surg. Lt.-Comdr. J. V. Williams to be Surg. Comdr.

Surg. Comdr. R. A. Brown to *President* for three months' course.

Surg. Lt.-Comdrs. M. J. Brosnan to *Pembroke* for R.M. Infirmary, Chatham; and D. C. Drake to *Maine*.

Surg. Comdrs. (D) E. G. Adams to *Victory* for R.N. Hospital, Haslar; J. T. Wood to *Pembroke* for R.N. Hospital, Chatham; and A. D. McHaffie to *Resource*, addl.

Surg. Lt. A. H. O'Malley transferred to *Emergency List*.

Surg. Lts. C. J. Mullen to *Pegasus*; and J. W. Oliver to *Queen Elizabeth*.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lts. C. A. Mather to *Victory* for R.N.B.; and H. R. Vickers to *Drake* for R.N.B.

### ROYAL ARMY MEDICAL CORPS

Lt.-Col. S. S. Dykes retires on ret. pay.

Lt.-Col. R. Gale, D.S.O., h.p. list (late R.A.M.C.), retires on ret. pay on account of ill-health.

Maj. H. B. F. Dixon, M.C., to be Lt.-Col.

Capt. H. N. Walker, h.p. list, is restd. to the estab.

Short Service Commissions: Lt. (on prob.) J. A. Dorran resigns his commission.

Candidates granted short service commissions as lieutenants on probation in the R.A.M.C.: J. Shields, St. Bartholomew's; C. W. Maisey, St. Thomas's; F. T. Moore, St. Bartholomew's; A. T. Marrable, St. Thomas's; R. J. G. Morrison, St. Bartholomew's; W. T. M. Moar, London Hospital; H. R. Simon, Trinity Coll., Dublin; J. A. Hamilton, Trinity Coll., Dublin; C. E. Watson, St. Thomas's; J. A. G. Carmichael, Guy's; W. G. Bateson, Queen's Univ., Belfast; S. E. Osborne, Guy's; E. S. Cooke, R. C. of P. and S., Ireland; A. C. Byles, St. Mary's; E. J. Crowe, R. C. of P. and S., Ireland; V. Bennett, Univ. Coll., Cork; J. W. Orr, Queen's Univ., Belfast; C. McGrath, Univ. Coll., Cork; T. M. W. D'Arcy, Univ. Coll., Dublin; G. N. Barker, St. Thomas's; C. J. O. Kelly, R. C. of P. and S., Ireland; R. A. Toledo, Univ. of Malta; N. C. Lendon, St. Mary's and Camb. Univ.; M. F. Kelleher, Univ. Coll., Cork; K. H. Harper, St. Bartholomew's; F. J. Hebb, Dalhousie Univ.; J. A. MacDougall, Univ. of Manitoba; J. C. A. Marchand, Univ. of Montreal; K. H. Foster, Univ. of Western Ontario; R. A. Hoey, St. Thomas's; J. M. Lynch, Univ. of Montreal; and P. Coleman, Univ. Coll., Cork.

### ARMY DENTAL CORPS

Maj. W. W. Pittuck, ret. pay, relinquishes his appt. under Art. 520 (b), Royal Warrant for Pay and Promotion, 1931.

### TERRITORIAL ARMY

Cpts. G. W. Wigg and E. R. C. Walker to be Maj's.

Lt. R. H. B. McCrae to be Capt.

C. H. G. Price (late Offr. Cadet, Bristol Univ. Contgt., Sen. Div., O.T.C.) to be Lt.

Supernumerary for Service with O.T.C.: Lt. W. S. Harvey (empld. Edinburgh Univ. Contgt. (Med. unit), Sen. Div., O.T.C.) to be Capt.

### ROYAL AIR FORCE

Flying Offr. P. A. Cooper to Aircraft Park, Lahore, India.

### INDIAN MEDICAL SERVICE

Cpts. G. Dockery and J. Quigley to be Maj's.

Lt. S. C. Misra relinquishes his temp. commn.

## CORRESPONDENCE

## FREUD'S EIGHTIETH BIRTHDAY

To the Editor of THE LANCET

SIR,—In the leading article on Freud's eightieth birthday in your issue of May 2nd you say :

"Freud's teachings involved a fundamental change of outlook, for they concern the unconscious motives of behaviour, the recognition of which runs counter to our philosophy and our pride, and to this rather than his insistence upon the importance of sex must be attributed the opposition encountered. This opposition, and the isolation that was forced upon him for years, undoubtedly influenced Freud's attitude to the scientific world."

And again :

"Useful criticism has, indeed, been lacking, for knowledge of the observations upon which the theory is based can only be obtained by making these observations oneself, and most criticism has consisted of a denial of the observations. Hence psycho-analytical doctrine has grown up without that healthy criticism which is both a stimulus and a check to scientific theory."

This is not so. Psychologists and psychiatrists found that Freud's writings contained nothing but assertions without even an attempt of proof, and a neglect, nay a defiance, of scientific method. Freud's writings were, therefore, simply ignored in Germany, *totgeschwiegen*, as Freud calls it. To substantiate these statements of mine is beyond the compass of a letter, but I have done so elsewhere. ("A Critical Examination of Psycho-analysis," London, 1923) and they have never been disproved. All that I have been told is that I have no right to criticise psycho-analysis as long as I have not been psycho-analysed myself, and this is probably what you mean by saying "knowledge of the observations upon which the theory is based can only be obtained by making these observations oneself." Now this is equivalent to saying, if you wish to study the effect of alcohol on a person, it is useless to observe a drunken man, but you can only do so when and whilst you are drunk yourself. A person who is being psycho-analysed is being put through a most intense subtle and refined process of *suggestion*, not for a quarter of an hour, but for hours, days, weeks, months, and sometimes even years. How many men are there that can free themselves from the religious and ethnical bias implanted in them in their youth, where suggestion was causal and discontinuous? A psychologist is as prone to suggestion as a doctor is liable to infection. Therefore, no person is less competent to form or give an unbiased opinion on psycho-analysis than he who has been psycho-analysed. Psychologists do *not* deny the observations and are quite willing to admit all that which psycho-analysts say they observe, but they differ from them in the interpretation of the observed facts.

That some good has come in the wake of psycho-analysis I readily grant: the doctor has ceased to regard the neurotic as a nuisance to be kept quiet during the consultation and to be prevented from talking about himself by keeping a thermometer in his mouth and then dismissing him with a prescription of Pot. Brom. and Tinct. Valerian. He, the doctor, has learned to try and understand his patient and to sympathise with him and readjust and re-educate him. On the other hand the harm psycho-analysis has done to the medical profession has not yet been realised. Promising young men approach the subject without prejudice and without suspicion,

enter the snare by allowing themselves to be psycho-analysed, and are then secure for psycho-analysis for the rest of their lives.

My advice to students is: Study psycho-analytic literature, observe the psycho-analyst at work, as you watch the surgeon doing his operation, but *never allow yourself to be psycho-analysed.*

I am, Sir, yours faithfully,

Shortlands, Kent, May 4th.

A. WOHLGEMUTH.

## VARICOSE VEIN INJECTIONS

To the Editor of THE LANCET

SIR,—I am glad that Dr. McAusland strongly advocates an empty vein technique, but I cannot agree that his methods of carrying it out are as reliable and effective. With regard to his first method, it is not possible to elevate the limb sufficiently because, in the well-elevated position, digital pressure seldom prevents the distal part of the vein emptying by other venous channels before the needle can be introduced, however quickly the patient lies down. In Dr. McAusland's second "dodge," he introduces the needle in the standing position. I am certain that, even in his expert hands, the needle sometimes comes out of the vein, however gently the patient tries to lie down. I notice that he then has to make sure that the needle is in the vein by withdrawing blood. With the described tourniquet technique the vein is frequently so "empty" that it is not possible to withdraw blood after the veins have visibly collapsed.

Although I only briefly referred to the application of firm pressure after the injection, I invariably apply Elastoplast over a considerable area for the reasons Dr. McAusland stated. I am, however, doubtful of the necessity of a pad of wool under the elastoplast.

I am, Sir, yours faithfully,

M. J. BENNETT-JONES.

Gambier-terrace, Liverpool, 1, May 4th.

## TREATMENT OF PHLEBITIS IN VARICOSE VEINS

To the Editor of THE LANCET

SIR,—Mr. R. T. Payne, in his letter of last week, says he feels an unnecessary boggy has been made of the danger of emboli in varicose veins. Though I have been in general practice for only 12 years, I have been present on two occasions when fatal pulmonary emboli have occurred in patients who were receiving treatment for spontaneous phlebitis in varicose veins.—I am, Sir, yours faithfully,

Sheerness, May 3rd.

M. DE LACEY.

## ACUTE FEBRILE ANÆMIA

To the Editor of THE LANCET

SIR,—In his interesting paper on a Case of Acute Febrile Anæmia in your last issue, Dr. P. C. Gibson mentions the term "acute breakdown of the blood," which he thinks was used by me. In reality at the clinical section of the Royal Society of Medicine (meeting of Oct. 9th, 1931) I headed the account of a remarkable case: "An Anæmic Breakdown or Crisis in a Child, not connected with definite Congenital Hæmolytic Jaundice—Rapid Recovery" (*Proceedings*, xxv., p. 9). This was just before I got to know of the observations of Lederer and others on "acute hæmolytic anæmia," and the case was perhaps the first definite example in a child to be

recorded in England. It was certainly one of "break-down," in which anæmia was the chief sign of the breakdown, but surely the term "acute breakdown of the blood" implies hæmoglobinuria as the chief symptom.—I am, Sir, yours faithfully,

London, W., May 4th.

F. PARKES WEBER.

## SEX AND CULTURE

*To the Editor of THE LANCET*

SIR,—In your issue of April 25th you publish from Dr. Rosslyn Earp a letter which may be thought to call for some reply from me. The situation seems to be that an American health periodical has published opinions that have hit Dr. Earp's mind in a place where the resistance to such ideas is great. But I am not concerned with this aspect of the matter so much as with the historical data to which Dr. Earp refers. In my book I classify a number of human societies, first according to the amount of continence, pre-nuptial and post-nuptial, inflicted by the sexual regulations they have chosen to adopt; secondly, according to their cultural behaviour. I define "culture" according to the manner, behaviouristically revealed, in which the members of a society express their attitude towards the external world. Thus I speak of deistic culture, rationalistic culture, &c. People in the deistic state think it right, proper, and necessary to erect buildings in which they try to maintain a right relation with the power (or powers) which, they think, controls the external world. I call these buildings "temples." The evidence is that in the past (1) different types of sexual regulations have always been accompanied by different types of cultural behaviour; (2) the same type of sexual regulations has always been accompanied by the same type of behaviour.

Dr. Earp is right, then, to say (even if he wishes it were not true) that there is a "correlation between temple-building and sexual restraint." But I regard the phrase as misleading; for it may imply that temple-building is the only type of cultural behaviour that is to be correlated in that manner. It would be more correct to say that temple-building is to be correlated with a certain degree of sexual restraint. Dr. Earp's point about Quakers shows that he has not yet been able to study the data closely. As I understand the matter, a Quaker meeting-house would come within the definition I place on "temple." In what he says about the Israelites Dr. Earp shows that he has not yet fully understood the conclusions I felt compelled to draw from the facts. The cultural behaviour of a society, or of any group within it, does not, and I do not think it can, depend on the sexual opportunity it enjoys, but on that enjoyed (or endured) by the two previous generations. Since we do not know the exact chronological position of many Israelite laws (e.g., Deut. xxii.) we cannot use Israelite history as evidence on which to base an induction. All the same, thinking that the minds of some readers would quickly run Israel-wards, I made some suggestions about Israelite history in my book.

Dr. Earp says that I live in a civilised society. Well, I may or may not; I do not know; it depends on what he means by "civilised." A use of this meaningless word takes away any meaning that another of his sentences may appear to possess.

I am, Sir, yours faithfully,

Cambridge House, S.E., April 28th.

J. D. UNWIN.

*To the Editor of THE LANCET*

SIR,—Dr. Earp is confessedly ignorant of the reason why temple-building is evidence of cultural progress. It is well known that the first evidence of any community ceasing to be utterly savage is the paying of post-funeral attention to the dead. Such attention shows that in the community concerned there is some idea of survival after death; the people have opinions about things beyond their immediate experience, and show imagination. Whether the main idea is to sustain the spirit till it can return to reinhabit its body, or to feed and propitiate it lest it exhibit malignancy, the result is substantially the same; there is a cult of the dead established. Temple-building follows closely. The spirit, and other spirits, the gods, are given homes; or places in which it is hoped they will stay. A culture may remain static at this stage; the temples being huts very little better than those of the community. But where the possibilities of a new building material are discovered—stone in Egypt, brick in Mesopotamia, earth faced by stone in Mexico—development is rapid. Permanent structures are provided for permanent requirements, the cult of the dead and the cults of the gods; often the one cult runs into the other, the great dead being deified. These requirements being part of the only permanent burden laid on the community, the temporary abodes of passing men, especially where climatic conditions permit, remain for long of the nature of hutments. Even incarnate gods such as the Egyptian Pharaohs are far more concerned with permanent provision for their post-funeral cults than they are with the lodging of their living bodies. By the time there are permanent temples, there are also permanent priest-hoods, no matter how recruited; and the gods have become localised, with a parallel system of human interest in or ownership of land. Under such circumstances, men, having already provided permanent homes for the deities instead of huts which require constant renewal, find opportunity to discharge the rest of their permanent burden for good and all, by endowment of temples with land in consideration of services to be rendered on behalf of the donors by the priests to the dead or to the gods. Thus corporate communities untouched by death—housed, owning property, and owing service, all in perpetuity—take their rise. The process which seems to have developed independently in Mesopotamia and in Egypt as well as elsewhere in the Near East, was repeated when Europe emerged from the Dark Ages. Our modern corporations are nothing but priesthoods divorced from religious conceptions; much of the business conducted by them first found its birth in the administration of temples and their relations with the secular community. The temples of Babylonia were the first banks of the world; the banking functions of other temples, including that of the Jewish Temple, have been traced. Any business Dr. Earp may transact through his bank or any income he may draw from investments are obtainable owing to a system deriving from the practices he considers "uncivilised."

Dr. Earp infers that there is some sharp differentiation between civilised and uncivilised peoples. But architecture arose from the necessity of providing permanent structures for the service of the cults; sculpture and painting and the manufacture of vessels from their ceremonial requirements; music to time the ritual movements; regularity and rule from the demand for a rite constantly repeated; and writing developed because the canon must not

be changed. All these things were later applied to secular purposes, and found a natural further development. But even before this stage, a culture which possesses all the arts, and deals with every variety of business; a culture which has determined how affairs may be carried on though men die, cannot be denied the hallmarks of civilisation. Modern civilisation shows nothing more and itself arose in precisely the same manner as those which are dead.

I am, Sir, yours faithfully,

Manea, March, Cambs, May 4th, 1936. C. T. NORRIS.

### THE NEW POISONS RULES

To the Editor of THE LANCET

SIR,—It would appear that, already, one of the requirements of the Poisons Rules which came into force to-day is being overlooked, to the inconvenience of both members of the medical profession and manufacturers and dealers. Rule No. 7 (3) (a) requires, *inter alia*, that the purpose for which the poison is required shall be indicated on the (signed) order. It would be to the greater convenience of members of the medical profession and of manufacturers and dealers if this point could be brought specially to the notice of those making out such orders.

We are, Sir, yours faithfully,

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS.

166, Piccadilly, W., May 1st.

### GASTRIC ACIDITY AND ITS SIGNIFICANCE

To the Editor of THE LANCET

SIR,—May I be allowed to add one more word to the recent discussion in your correspondence columns suscitated by Prof. Apperly's statement that anæmia lowered and abolished gastric acidity, and that in achlorhydric anæmia the ordinary view that the

achlorhydria caused or contributed to the anæmia would sometimes have to be reversed. Dr. Alvarez has suggested (March 28th, p. 741) that severe anæmia accompanied by abnormally high gastric acidity was probably always due to a bleeding ulcer. In a paper on ancylostoma anæmia (THE LANCET, 1934, ii., 299) Prof. A. G. Biggam and I, analysing a series of about 120 cases, stated that gastric juice analysis rarely revealed achlorhydria; in fact it was found in only five cases. The hæmoglobin percentages in these cases were 42, 44, 24, 24, 55, while the average hæmoglobin percentage of the whole series was 27·8, reaching in some cases values as low as 10. In a small number of cases I am following at present the corresponding values of hæmoglobin percentage and gastric acidity are these:—

Red cells in millions	..	0·89	2·4	2·76	1·9	3·7	3·2	2·6	4·0	2·6
Hæmoglobin per cent.	..	15	18	20	25	26	30	40	45	46
Maxim. free acidity c.c.m N/10 HCl		80	10	75	38	53	33	60	75	65
Maximum total acidity	..	110	20	95	54	75	70	96	95	95

It can easily be seen from this series that there is not the least relation between hæmoglobin percentage and gastric acidity in ancylostoma anæmia. Prof. Soliman Azmy Bey and his collaborators (Azmy, S., Gaafar, M., and Noshokaty, H., Jour. Trop. Med. and Hyg., 1934, xxxvii., 311) studying another series of ancylostoma infection also reached the same conclusions, only two cases out of 24 showing achlorhydria.

I am, Sir, yours faithfully,

PAUL GHALIOUNGUI,  
Tutor, Faculty of Medicine, Cairo.

April 25th.

## PUBLIC HEALTH

### Coördination of Hospitals

MANCHESTER

THAT the joint hospitals board set up in Manchester is a practical body and not merely deliberative is shown by the recommendations it has recently made to the city council. The board is composed not only of representatives of the voluntary hospitals in the manner prescribed by Section 13 of the Act of 1929, but also of the city council and the university. It has had before it a memorandum prepared by the medical officer of health (Dr. R. Veitch Clark) on the association between the staffs of voluntary and council general hospitals, of which latter there are three—viz., Crumpsall, Withington, and Booth Hall. At first it had seemed reasonable to link each of these to its nearest voluntary neighbour, but there were certain disadvantages in such an arrangement. The consulting staff of the teaching hospital, the Royal Infirmary, carried—in the public eye at least—a higher status than those in other voluntary hospitals, and their services should be potentially available not merely to the adjacent council hospital. Moreover, the consulting staff of the non-teaching hospitals was not stable, since they naturally tended to move to the infirmary when occasion offered, and their number in any one such hospital might not be sufficient to afford the council a field for selection. The desirable coöperation of hospitals in groups

might be further explored by means of meetings of the medical and surgical staffs convened under the auspices of the board. These the board decided to arrange.

To assist the council in its appointment of consultants the board has suggested that an advisory panel should be recognised by the city council, consisting of the chairman of the public health committee (Councillor Meadowcroft), Councillor Edwards, the chairman of the joint board (Sir Christopher Needham), the chairman of the medical and surgical staff subcommittee (Mr. W. Cobbett), the vice-chancellor of the university (Prof. J. S. B. Stopford), and the medical officer of health. In special branches of medicine it would consult certain nominated advisers. It would submit a short list of applicants to the public health committee. This proposal may not be equally welcome to all sections of the council, but it should relieve them of a troublesome task and improve the selection of professional candidates, at least in the first stage of the process. It will be interesting to see the council's reaction to it.

The board further recommends that a sufficient number of consultants should be appointed, each making two weekly visits to the council hospital to which they are attached, rather than a smaller number visiting thrice weekly. Perhaps the most important suggestion of all is that senior consultants should be appointed to municipal hospitals as directors, in an honorary capacity. They would foster

coöperation between voluntary and council hospitals and the university, guide new developments, and encourage research.

## SCOTLAND

Since the passage of the Act of 1929, the Scottish Department of Health has repeatedly urged local authorities to depart from a parochial outlook in relation to hospital provision and to think rather in terms of regions than areas of local government.<sup>1</sup> In its latest report<sup>2</sup> the department, while mentioning that collaboration has proved difficult to secure and finding a partial explanation in the tendency to mark time till the Committee on Scottish Health Services has reported, does record some advance. In Paisley, for example, the need for a new maternity hospital has been the occasion for a proposal to acquire a site in contiguity with the fever hospital and of sufficient size to meet other hospital needs. The council, at the same time, has approached other authorities and voluntary bodies with the object of exploring a scheme larger than that required by the town itself. The counties of Dumfries, Kirkcudbright, and Wigton apparently appreciate the desirability of forming a joint hospital scheme and have met for its discussion. The department points out that the Dumfries and Galloway Royal Infirmary (a voluntary hospital) would form its natural centre. As the extension of this institution is under consideration by its directors, the moment for coöperation between them and the local authorities seems favourable. A regional system, not only for hospital administration but also for public health purposes, seems to find favour with many Scottish practitioners and, if

<sup>2</sup> Seventh Annual Report of the Department of Health for Scotland, 1935. H.M. Stationery Office. Cmd. 5123. 3s. 6d.

the Committee on Scottish Health Services proposes to deal with this idea, its report, which is due at an early date, should be of particular interest.

## INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 25TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1896; diphtheria, 892; enteric fever, 30; pneumonia (primary or influenzal), 929; puerperal fever, 48; puerperal pyrexia, 129; cerebrospinal fever, 24; acute poliomyelitis, 6; encephalitis lethargica, 4; dysentery, 24; ophthalmia neonatorum, 97. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 1st was 6303, which included: Scarlet fever, 1007; diphtheria, 889; measles, 3118; whooping-cough, 562; puerperal fever, 13 mothers (plus 9 babies); encephalitis lethargica, 283; poliomyelitis, 5. At St. Margaret's Hospital there were 23 babies (plus 8 mothers) with ophthalmia neonatorum.

*Deaths.*—In 122 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 104 (57) from measles, 6 (0) from scarlet fever, 42 (17) from whooping-cough, 33 (4) from diphtheria, 41 (17) from diarrhoea and enteritis under two years, and 72 (11) from influenza. The figures in parentheses are those for London itself.

Measles remains the fatal infectious malady of the period, the number of deaths for the last eight weeks (working backwards) being 104, 102, 103, 81, 104, 114, 105, 84 for the country as a whole, and 70, 68, 60, 43, 62, 62, 58, 47 for Greater London. Deaths were reported from 31 great towns: Leeds and Liverpool each reported 4, Southampton, Manchester, and Sheffield each 3; no other great town more than 2. Liverpool reported 6 deaths from whooping-cough, Birmingham 5. Deaths from diphtheria were reported from 22 great towns, 3 each from Manchester and Sheffield.

The number of stillbirths notified during the week was 315 (corresponding to a rate of 43 per 1000 total births), including 51 in London.

## PANEL AND CONTRACT PRACTICE

## "No Deposit, No Treatment"

THERE is still, it seems, some misunderstanding about the position of the practitioner when treatment is required by an applicant who produces no medical card or a card which the doctor has been informed is invalid. In the latter event the natural thing is to say: "Oh no, you have been removed from my list as having ceased to be insured; if you want treatment you must pay for it"—and up to a point Clause 7 (2) permits this. The clause safeguards the position both of the doctor and of the applicant; the doctor may demand and accept a reasonable fee provided he gives a receipt on the appropriate form; and the applicant, if he proves eligibility to obtain treatment from the doctor, has the fee refunded to him from the doctor's remuneration. The doctor has in effect drawn part of his remuneration in advance, has treated the applicant as an insured person (except that he must not issue insurance prescriptions until title is proved) and has the patient's name added to his list as from the date on which treatment was first given. If the applicant does not prove his eligibility to obtain treatment the doctor keeps the deposit. Instead of charging a fee the doctor may issue a formal notice of his intention to render an account, and sometimes, especially when the doctor is more or less satisfied of the bona fides of the applicant, this may be preferred to a cash payment.

Suppose, however, the applicant demands treatment but refuses to pay a reasonable sum by way of

deposit. It must be remembered that the clause says that if a person in applying for treatment represents that he is an insured person the practitioner is required to give any necessary treatment, and it might appear therefore that anybody who cares to claim that he is insured may obtain free medical advice merely by refusing to pay a deposit. Some time ago this point arose in connexion with an appeal by a practitioner, and it was then pointed out that the clause also contains the phrase "but the practitioner may demand and accept from the applicant a reasonable fee," and that the clause applies to cases in which there is strong prima-facie ground for thinking that the applicant is not entitled to medical benefit and consequently that the funds at the disposal of the insurance committee for payment to practitioners are not calculated to cover the provision of treatment. Clearly the clause must be read as a whole, and the words quoted above construed as limiting the obligation which in their absence would be an absolute obligation to treat. Hence, in a case where not only is a fee not tendered but liability to pay is expressly repudiated it appears that the obligation to treat does not arise. The clause entitles the practitioner not merely to "accept" a fee but to "demand" one, and the latter word implies that the doctor may make his offer of treatment conditional at any rate on an acceptance of liability. The contrary view would deprive the word "demand" of most, if not all, of its effect.

In the extreme case, then, the practitioner may

quite properly say "no deposit, no treatment" if he wishes.

### Hæmorrhage Following Dental Extractions

An insured person had teeth extracted one afternoon, and during the early evening had to return to the dentist who plugged the gums to arrest hæmorrhage. After she went to bed bleeding recommenced and at 11.30 P.M. the insurance doctor was asked to visit the patient. The doctor replied that dental treatment did not come under the Insurance Act, that the proper course was to get the dentist who caused the bleeding to come and stop it, and that if the dentist had any difficulty the doctor would, at the request and cost of the dentist, come to his aid. The employer called in his own doctor who did what was necessary. The local medical committee took the view that the hæmorrhage was a matter which should have been attended to by the dentist "as dentists are specially qualified to deal with such matters." The insurance committee contended that the service fell within the practitioner's obligations, and with this view the referees agreed.

The question was not whether the service was one which could properly be undertaken "by a general practitioner of ordinary professional competence and skill" (so ran the phrase when the question arose some years ago), but whether it was treatment—that is medical attendance and treatment—within the meaning of the regulations. The referees felt some difficulty even in formulating the view that the

arrest of hæmorrhage from the gums, occurring seven hours after the extraction of teeth, was not medical treatment. If the care of an injury of this nature, admittedly within the competence of the practitioner, was not medical treatment, they were at a loss what meaning to attach to the term. Their report reads as follows:—

The contention of the local medical committee, that it should have been attended to by the dentist as dentists are specially qualified to deal with such matters, is apparently an expression of the view that the dentist would have stopped the hæmorrhage more efficiently. This may, or may not, be so. But the local medical committee can hardly seriously contend that a practitioner is to be excused from rendering a service within his agreement because he is of opinion that some other person would perform the service better. The contention may, however, mean that it was the duty of the dentist to stop the bleeding—though no evidence is offered that the dentist was available for the purpose. On this hypothesis again we fail to see the relevance of this contention. A failure in duty on the part of one person is not an excuse for the failure of another to perform a contract with, and for the benefit of, persons in no way privy to the failure.

The bleeding at 11.30 in the night was a matter calling for the medical treatment which the practitioner was bound to give, and his obligations were in no way affected by the origin of the bleeding.

This ruling is worth calling to mind again now. Although doctors may charge for administering an anæsthetic in connexion with dental extractions they must deal with hæmorrhage as part of their obligations under the terms of service.

## PARLIAMENTARY INTELLIGENCE

### SECOND READING OF THE MIDWIVES BILL

#### Moved by the Minister of Health

ON April 30th, in the House of Commons, Sir KINGSLEY WOOD moved the second reading of the Midwives Bill. He said the main purpose of the Bill was to establish an active service of salaried trained midwives so as to ensure that every expectant mother, whatever her circumstances, would be able to obtain the services of a qualified midwife. The Bill was also designed to raise the status of the midwifery profession by providing adequate salaries and sure prospects to those entering the new service; and also to ensure further facilities for their instruction. The problem was a baffling one. In England and Wales the local authorities in 1926-27 were spending on maternity and child welfare services some £2,000,000 per annum. Last year over £3,000,000. Yet the maternal mortality-rate had not yet been substantially reduced. It affected all classes of the community. It varied from place to place, and they were not yet in a position to speak with certainty and authority as to all its causes.

The position of the midwifery service in this country at the present moment was by no means satisfactory. It had for the most part been a poorly remunerated service, without much status and prospects which were not improving. It was an overcrowded profession. Except for a small minority the practice of the independent midwife did not afford a living wage, and the reasonable livelihood of the few was often obtained only by attendance on an unreasonable number of cases involving much physical and mental strain. There were too many part-timers. (Cheers.) There were also midwives who continued to practise when they were past their work. There were also numbers of unqualified women and there was nothing to prevent them from attending and charging for their attendance as maternity nurses of women in childbirth. Finally, there was a lack of coördination between the work of the independent midwives, excellent though it was, and the health services in many areas.

### SUPERVISING AUTHORITIES

The Bill provided that the organisation of the new service should be entrusted to local authorities who were the local supervising authorities under the Midwives Act. Each supervising authority was required to secure the whole-time employment of a sufficient number of midwives for attendance, not only as midwives, but as maternity nurses in order to meet the needs of the area for domiciliary midwifery and the authority would carry out this duty by making arrangements with voluntary organisations or where necessary by themselves employing midwives. He wished to emphasise that coöperation with the doctors and with voluntary hospitals and agencies was essential to the success of this proposal. Where the supervising authority was not a maternity and child welfare authority coöperation with the work of the antenatal clinics was essential. One of the difficulties in London would be to work out a scheme which would include the service of salaried midwives already provided by a number of voluntary hospitals which took no account of borough boundaries. About 25 per cent. of all confinements in London took place in L.C.C. hospitals at which there were antenatal clinics and where specialists in all branches of maternity work were available. Salaried midwives appointed by the L.C.C. could therefore enlarge their experience by taking duty in hospitals when they were not engaged in domiciliary work.

One of the main principles of the Bill was designed to ensure that efficient voluntary organisations should have a proper and adequate share in locally coördinated schemes and all such organisations which employed salaried midwives must at once be consulted, when the Bill was passed and the proposals had to be put into operation by the local supervising authority as to the arrangements for the new service. The voluntary associations would have the right if they were dissatisfied with any arrangements which were contemplated to make direct representations to the Minister of Health. It would be the duty of the Minister to see that proper agreements were entered

into and proper payments were made so as to secure an adequate service and the extension, wherever desirable and practicable, of their work.

#### SALARIES AND SUPERANNUATION

The local authority would fix the salaries of midwives employed by them and the fees to be charged for their services, and in recovering such fees they would have regard to the financial circumstances in each case. The salaries of the midwives, and fees to be charged in relation to the work of voluntary associations, would be a matter of negotiation between the local authority and the voluntary organisations, but the local authority would be asked to fix their grant to voluntary organisations on a basis which would ensure that the salaries and fees would correspond closely to those adopted by the local authority. A midwife who was practising at the present time could apply for a salaried post, or she could continue in an independent practice if she so cared. On the other hand, if she surrendered her certificate within three years of the coming into operation of the scheme and cared to take this course she would receive compensation equivalent to three times the average of her emoluments for the preceding three years. There were also a number of old or infirm midwives unable to perform satisfactorily their duties, and in these cases the local authority might call upon the midwife to retire, in which case she would receive as compensation a sum equal to five times the net value of her practice during the previous three years. In suitable cases the local authority, instead of paying compensation in a lump sum, would be able to purchase for the midwife an annuity terminable at the age of 70, or at death, if that occurred before she reached that age.

Arrangements were also provided for under the Bill which would enable midwives to keep up to date by attending from time to time post-certificate or refresher courses. The receipt of compensation, or the payment of an annuity provided for in the Bill, would in no way affect the title of a midwife to a contributory pension. He had also taken power in the Bill to deal with the question of unqualified persons. At present any unqualified woman might nurse a woman in confinement if a doctor had been engaged and she worked nominally under his supervision and direction. Such employment was dangerous both to the mothers and to the children. No doctor who worked with an uncertified woman could always be sure that he would be at hand at the critical time, and it was unanimously agreed by the Departmental Committee that the practice of attending a confinement in such circumstances did not conform to a reasonable degree of security, even in normal cases. In the Bill the Minister of Health was empowered, when an adequate salaried midwifery service was in being and not before, in any area or county district to make an Order under which it would be an offence for any person who was neither a midwife nor a registered nurse to receive remuneration for attending as a nurse a woman in childbirth, or at any time during the ten days immediately after the birth.

#### MIDWIFE AND DOCTOR

The Bill did not in any way prejudice the position of medical practitioners, but he thought the general practitioner should benefit considerably when the provisions of Clause 6 became operative as he would always be sure of the assistance of a certificated midwife, whereas at present he had to rely in many cases upon the services of an untrained woman, and in areas where such a course was customary mothers would no doubt continue to engage doctors as now for their confinement, and it was intended that not only the doctor but the mother, wherever practicable, should have a free choice of midwife to act as maternity nurse, and that nothing should be done which would in any way interfere with her preference for a particular doctor.

In bringing forward these proposals, he recognised, the Minister said, that other steps might be necessary.

Hon. Members might remember the statement he made a little while ago in relation to a more special line of attack which was in progress—namely, a series of special investigations that had been undertaken and in a number of administrative areas, primarily those in which the rates of maternal mortality had been persistently above the average for a period of years. Investigations were also being made for the purpose of comparison in some areas comparable in general characteristics with the areas of high maternal mortality, but in which the rates had been relatively low. The aim of these investigations had been, in the first place, to give assistance to the local authorities to devise any immediate practical improvements which might suggest themselves, but also, and more particularly, to see whether they could not obtain any further material which would help them to elucidate the underlying causes of high maternal mortality-rates in general. The result of these investigations would, he hoped, be available at the end of this year. In the meanwhile they would be acting in the best interests of motherhood by proceeding immediately with the proposals in this Bill.

#### Debate on the Motion

Mr. ARTHUR GREENWOOD said he welcomed the Bill for what it was worth. It was nothing more than a slight extension of the existing law making it a little easier for local authorities to carry out the powers which they already possessed. After all the experimentation of past years the time had now arrived not for small piecemeal measures but for a far-flung comprehensive policy and an attack on this problem on a wide front. Maternal mortality was a social problem for which the House of Commons was responsible. The first step, it seemed to him, was to make sure that expectant mothers were properly fed. There ought to be more effective antenatal care, more maternity hospitals within the reach of working-class housewives, and the services of skilled gynaecologists behind the midwife. The Bill provided only a ten days' service. That period had become the practice through poverty, not because of medical knowledge. It was not right to expect a woman who had undergone a trial of that kind to be up and about after ten days and to carry all the responsibilities of the household.

Major HILLS said he would like to see the minimum of ten days' attendance of a midwife raised. He thought they would get more efficient service if they allowed midwifery to be run by the smaller local authorities which complied with the standard laid down by the Local Government Act of 1929. Clause 6 of the Bill abolished the maternity nurse who usurped the midwife's function. If she endangered health she ought to go, but he was doubtful whether they could do without a secondary service. He suggested that they should train a body on the lines of the home helps now working in Birmingham, or of the after-care nurses who had been used with great success in Holland. Would the Minister try to induce the C.M.B. to increase the period of training of midwives to two years? If that could be done they would get a splendid service.

Mr. HOLLAND said what was needed was a complete national maternity scheme including supervisory clinics within easy reach of the mothers' homes, staffed by doctors with special knowledge and experience in obstetrics. There should also be health visitors, improved housing conditions, better nutrition for the mother, and rest hospitals with proper equipment and staffs.

Sir FRANCIS FREMANTLE said that the real object before them was to establish and enlarge and improve both in quantity and quality the profession of midwives. The number of midwives was going to be cut down, probably to half what it was at present, and that half was going to be much more hardily treated from a professional point of view and higher requirements demanded of it. All the speeches had taken it for granted—including that of the Minister—that the flow of recruits would come in, but was that

the case? That was the real problem before them. What were the inducements to young girls of good education and standing to take up the great burden of training for this extraordinarily hard and arduous life with all its difficulties? It was only natural, even if their bent was towards nursing the sick, that they should prefer to go in for general nursing rather than midwifery. The financial scales and conditions of service under the Bill, though better than they had been hitherto, were to his mind quite inadequate to bring in the right kind of persons. Who was to be the right authority to supervise this service? It could not be done by an authority which employed two or three midwives, which had a small rateable value and had no skilled superior officers. He trusted therefore that they would consider in Committee whether it was not better to put this new service under the county councils rather than under smaller authorities. He hoped that regulations would be made in the Bill or afterwards by which complete facilities would be given to midwives to work under all the different organisations and that they would be trained and encouraged to work for the best of their profession, wherever they were and in whatever circumstances. There were nearly 60,000 midwives, and of those 18,000 gave notice of their intention to practise in the year before last, and out of that number only 16,000 practised. What was really wanted—and it was not dealt within the Bill—was some kind of multiplication of the sources of training for those women who wanted to put C.M.B. after their name. This was a most pressing problem both to nursing schools and midwifery schools in London. There should be some kind of intermediate qualification for women who intended to be equipped if necessary for occasional demands made upon them for midwifery or maternity nursing. There was one point in regard to which he could not see how the Bill could be worked. Provision was to be made for entirely whole-time midwives. That would be possible in busy towns, but impossible in country districts, if "whole-time midwives" meant that they were to be midwives and nothing else. It would be impossible, for instance, in the mountain valleys of Wales to arrange a service of full-time midwives. They would have to continue the system of district nurses under the county nursing organisations which had done such valuable work, where there were well-trained midwives, and where by means of timely refresher courses they were kept up to the mark.

Mr. KEELING said he had been asked by the Westminster city council, of which he was a member, to give its views on the Bill; those views were shared by practically all the other metropolitan borough councils. These borough councils regretted they had not been made the authorities for midwives under the Bill. They thought that there were several reasons why they should be preferred to the L.C.C. First, they were already the maternity and child welfare authorities in their areas and were carrying out most of the duties prescribed in the Bill. Secondly, the population of each London borough was larger than the population of a great many provincial county boroughs, all of which were to be the authorities for midwives under the Bill. Finally, and most important, the maternity services in London were far superior to those in the country as a whole. It was true that there were only three metropolitan borough councils which were employing their own midwives, but there was a very good reason for that. Most of the London boroughs found they could provide midwifery service much better by making arrangements with the great London voluntary hospitals whose maternity services were second to none, or with the nursing associations. Under that arrangement the midwife worked with the hospital as a base and the organisation of the hospital was at her back to give her assistance. The Minister had mentioned that 25 per cent. of births in London took place in L.C.C. hospitals; he would point out that another 25 per cent. took place in the voluntary hospitals. Many of the London borough councils

already went much further than this Bill. They subsidised maternity beds in hospitals and arranged for gynaecologists to be available for consultation in serious cases. They also financed bacteriological services. Each of the London borough councils had also one or more maternity centres with which the midwives worked in close association. All these services were available free of charge when necessary. What was required in London was not revolution or reconstruction but development.

Mrs. TATE said it was useless to have better training for midwives if there was not far better training for doctors also.

Mr. FRANKEL thought they ought to ensure by means of some provision in the Bill that this new service would be in the hands of authorities who might be relied upon to take the responsibility for this supremely important work. There should be no farming-out of this responsibility to smaller authorities or to voluntary organisations unless they were of proved capacity. Not only ought there to be salaried midwives, but those midwives ought to have strong medical support. Under the Bill midwives ought to have the power to call in a real expert rather than a general practitioner as was now the case.

Sir GEORGE JONES said he thought the Government were right in the decision that the larger supervising authorities were the best for this purpose. Most people connected with London administration agreed that it was desirable that there should be one authority for London under the Bill. An excellent domiciliary service had been organised by the London voluntary hospitals acting independently of the borough councils, and it would be a calamity if anything were done which would diminish the splendid work which the voluntary hospitals were doing.

Major MILNER said he regretted that the new midwifery service would not be in the real sense a national one. He had hoped that the status of midwives might have been made akin to that of civil servants. In this Bill duties were being imposed on local authorities without the proper financial assistance to carry them out. He strongly supported the plea that the compensation paid to midwives who left either voluntarily or compulsorily should be a national and not a local charge. The services of a midwife should, he thought, be available for at least 14 days instead of 10.

Sir JOHN MELLOR said he felt with many others that there should be included among the authorities who would administer the Bill those county districts which had a maternity and child welfare committee under the Act of 1918, and a whole-time medical officer, and were of sufficient size to conduct the administration.

Mr. DUNN suggested that midwives should in future be given special training in the newer anaesthetic appliances.

Mr. RHYNS DAVIES said that a Bill which merely raised the status of midwives would not avail very much in reducing maternal mortality. The issue was deeper than that. Malnutrition and unemployment must have something to do with the problem. He was satisfied that the measure would provide the country with better nurses.

#### The Parliamentary Secretary's Reply

Mr. SHAKESPEARE said that the Minister had reason for satisfaction at the almost unanimous approval that had been given to the Bill. The term of ten days was fixed by the rules of the Central Midwives Board for midwives acting as such, but there were no rules as to the period for maternity nursing and the Government took a step forward in saying that a midwife acting as a maternity nurse should attend on the mother for at least ten days. If in the circumstances of the case the doctor or the midwife decided that there was need for further attention they could give it. There was considerable opinion among the medical profession that from the point of view of nursing ten days was not enough. If the Central Midwives Board considered changing

the rules with regard to midwives employed as such it would be necessary to change the rule here as regarded the period of attendance of midwives acting as maternity nurses. The Joint Council of Midwifery estimated on certain assumptions that roughly 4500 new salaried midwives would be necessary. Voluntary associations formed in future could be consulted by the supervisory authority and they could come into the scheme. It was certainly hoped that training would be improved. Training places would be reserved for those who intended to practise.

The new expenditure would be calculated in relation to the expenditure incurred in the year ending March 31st, 1936. In the case of direct employment under a supervising authority there would be a unit of cost based on the average net annual cost throughout the country incurred in respect of the employment of a midwife. That unit had not yet been fixed, at the special request of the local authorities who wished to have more information as to what salaries were being paid and what fees were being charged. On the question of the administrative working of the scheme, the Government had come down on the side of the larger authority—the hospitals authority—because that was in line with the whole trend of modern county government. If they entrusted this service to the smaller authority it would be difficult to provide a sufficient number of midwives so that there could be reliefs in case of sickness or holidays. The Minister of Health was always sympathetic in considering an application (under Section 62 of the Local Government Act, 1929) whereby a maternity and child welfare authority employing a whole-time medical officer of health could itself apply to be made a supervising authority. He agreed that there was at present a good deal of overlapping. In future where they had a salaried service under a large supervising authority they would be able to assure a much closer coöperation between the authorities. A midwife in the country would be able to practise nursing and other nursing services. As long as she gave full-time service she could carry on nursing work in the ordinary way when not employed as a midwife.

The Bill was read a second time.

## NOTES ON CURRENT TOPICS

### Supply of Medicines on Sunday

When the Shops (Sunday Trading Restriction) Bill as amended in Standing Committee was considered on report, Mr. WAKEFIELD moved an amendment providing that registered pharmacists employed on Sundays in those shops which had to open for the serving of customers in pursuance of a contract with a national health insurance committee should not be required to receive the compensatory half-holiday, subject to the conditions that the pharmacists must not be employed for more than two hours on the Sunday and have not been employed on the previous Sunday; and that they must receive compensatory time off in the week. He explained that under the contracts which national health insurance societies had with chemists a service must be provided at reasonable hours. Under the regulations a chemist was required to supply with reasonable promptness to any person who presented an order for drugs on a prescription form provided by the committee for the purpose and signed by any practitioner in the medical list of the committee, or his deputy or assistant, such drugs or appliances as were so ordered. The usual times for opening on Sunday were from 5 to 6, or 6.30 to 7.30, or some similar time. The object of the amendment was to ensure that qualified assistants who were employed in this way should receive time off. In the Bill as it stood if a qualified assistant was dispensing for just that one hour, or for half an hour, some of these urgent medicines or drugs it would be necessary for the employer to give him an additional four hours off. It was clear that that would place the chemist, especially a small man in a small town, in an impossible position. He

required his qualified man during the week when business was at its peak and dispensing was most required. This service was not operated for profit; only urgent medicines and goods could be supplied on a Sunday. The amendment had the full approval of the various pharmaceutical interests, that was to say, the insurance committees, the National Pharmaceutical Union, and the Pharmaceutical Society. The Pharmaceutical Society had 22,000 registered pharmacists in membership. It was not proposed that there should be any exemption for any unqualified assistant, or any body other than the registered professional pharmacist.

Mr. LESLIE said he was speaking for the qualified men who were organised in the pharmaceutical section of the Shop Assistants' Union. Speaking from the dispensers' point of view they felt that if they were to give their services on Sunday they should get the time off which was allowed to other assistants. He opposed the amendment, and he hoped that the House would vote for the Bill as it stood.

After further debate, Mr. LLOYD, speaking for the Home Office, said that the amendment applied only to those chemists' shops which had to be open on Sunday under contract, to qualified assistants, and to those who were employed for not more than two hours on alternate Sundays. After consultation with the Ministry of Health the Home Office thought that the amendment should be accepted, in view of its extremely limited character.

The amendment was carried by 120 votes to 61.

### The Public Health Bill

In the House of Commons on May 4th the following members were appointed to form a Select Committee of seven to join with the Committee appointed by the House of Lords to consider the Public Health Bill: Sir Francis Acland, Sir Francis Fremantle, Mr. Leach, Major Milner, Mr. Shakespeare, and Mr. H. G. Williams.

The Royal Pension Fund for Nurses Bill (which has passed through the House of Lords) was read the third time and passed without amendment.

## HOUSE OF COMMONS

WEDNESDAY, APRIL 29TH

### Medical Service in West Africa

Dr. LEECH asked the Secretary of State for the Colonies whether he was aware that the conditions of service and rates of pay of the West African section of the colonial medical service had recently been revised; that this revision had caused such dissatisfaction as to compel the Nigerian section to memorialise his department; and what action he proposed to take in the matter.—Mr. THOMAS replied: The answer to the first part of the question is in the affirmative. I have recently received, through the Governor of Nigeria, a memorial from the members of the colonial medical service serving in Nigeria, which is receiving consideration.

THURSDAY, APRIL 30TH

### Juvenile Trainees and Malnutrition

Mr. GEORGE HALL asked the Minister of Labour the result of his inquiries into the malnutrition existing amongst trainees attending juvenile instruction centres; and whether he was now prepared to recommend that local authorities be empowered to supply meals as well as milk in such cases.—Mr. ERNEST BROWN replied: In reply to a question by the hon. Member on Feb. 27th I said that I was making inquiries into the adequacy of the existing arrangements for the provision of milk in the junior instruction centres in the county of Glamorgan. An inquiry into this question has been made in collaboration with the President of the Board of Education, and I am satisfied that the arrangements for the provision of milk as medical treatment are adequate. I am now extending the inquiry to other areas. As the hon. Member is aware, local education authorities have no power to

provide ordinary meals in junior instruction centres, and the decision not to seek such power was in accordance with the recommendation of the National Advisory Council for Juvenile Employment. I propose, however, at an early date to ask the council to review the operation of the system of authorised courses and the question of providing meals in centres will no doubt be considered by them.

Mr. HALL: Is the right hon. gentleman aware that milk has been supplied to the trainees attending the centres for some time, and notwithstanding that 57 per cent. of them have been certified to be suffering from malnutrition? Is not the matter sufficiently serious for the right hon. gentleman to complete negotiations to provide meals as well as milk?—Mr. BROWN: I have no powers, but I propose with these facts in mind to ask the advisory committee to go into the matter at an early date.

#### Pollution of Water-supply in Lancashire

Sir ROBERT YOUNG asked the Minister of Health whether he had received any report of the bad conditions of the Golborne, Lancashire, water-supply; whether he was aware that the water services were practically choked with manganese dioxide, and that the supply of drinking water was often dirty; and whether he would take steps to remedy this matter in the interests of public health.—Sir KINGSLEY WOOD replied: I have received a communication, which refers to pollution by manganese dioxide, from the Golborne Urban District Council. I am communicating with the authorities concerned.

#### Registration of Births: Mother's Age

Mr. RANKIN asked the Minister of Health whether, in order to measure correctly the fertility of the population, he would arrange for the records of the Registrar-General in future to show the age of the mother at the birth of each child, as was recorded in nearly every other country, and whereby alone a proper diagnosis of the situation could be made.—Sir KINGSLEY WOOD replied: It has for some time been the intention to make this alteration in the birth registers on the first suitable occasion, having regard to the complicated administrative adjustments and preparations involved, and steps are now being taken to make the change.

#### Maternity Treatment: Liverpool Minnitt Apparatus

Mr. RANKIN asked the Minister of Health if he would state in which hospitals operated by local authorities the Liverpool Minnitt apparatus was available in respect of maternity cases.—Sir KINGSLEY WOOD replied: I regret that this information is not available.

#### Accredited Milk Licences

Mr. ASSHETON asked the Minister of Health (1) if he was aware that injustice was being done to many farmers owing to the lack of uniformity of standard of farm buildings required by different county councils as a condition of the grant of an accredited milk licence; and if he would investigate this matter; and (2) if he could explain why there were 2092 farmers in Cheshire licensed for accredited milk production, whereas there were only 447 in Lancashire and 427 in the West Riding of Yorkshire; and to what extent this was due to the lack of uniformity in the standard of farm buildings required as a condition of the grant of an accredited milk licence.—Sir KINGSLEY WOOD replied: I am aware that there is said to be a lack of uniformity between the requirements of certain county councils for the granting of Grade A milk producers' licences which are necessary before the producers are included in the list of accredited producers kept by the Milk Marketing Board. I do not consider it practicable to lay down a detailed code, but in a recent circular I have drawn the attention of local authorities to the principles by which they should be guided. I have offered to give the authorities such assistance as I can with due regard to the exercise of my jurisdiction in the matter of appeals upon individual cases.

#### Anti-tetanus Serum

Mr. ROSTRON DUCKWORTH asked the Minister of Health whether any local authorities provided centres at which

anti-tetanus serum was readily obtainable by medical practitioners; and whether, if such a policy met with the approval of his department, he would advise local authorities not making such provision to do so.—Sir KINGSLEY WOOD replied: I am not aware that any local authorities have provided centres for this purpose, but in one or two cases sanction has been given by my department under Section 133 of the Public Health Act, 1875, empowering an authority to provide temporary supplies of the serum for the poorer inhabitants of their district. As regards the last part of the question, I am advised that the serum is readily obtainable through ordinary trade channels, and that if it were stocked generally by local authorities only a very small proportion of their stocks would be likely to be used and the greater part would become inert and be wasted.

#### Silicosis Certificates in South Wales

Mr. JAMES GRIFFITHS asked the Home Secretary the number of applications for certificates from among the South Wales miners made to the Medical Board under the Various Industries (Silicosis) Schemes, and the number who were granted and refused certificates each year from 1931 to date.—Sir JOHN SIMON replied: The following table gives the information asked for on applications dealt with by the Silicosis Medical Board from South Wales miners or their dependants so far as it is available:—

	Death certificates.		Disablement or suspension certificates.	
	Granted.	Refused.	Granted.	Refused.
1931 (1st June) to 1933 (December) ..	69	•	329	•
1934 .. .. .	33	20	186	124
1935 .. .. .	45	16	192	137

\* Separate figures for South Wales are not available. For the whole coal-mining industry the refusals during the period referred to were 21 and 169 respectively, and the certificates granted 92 and 370.

#### Health Insurance: Regional Medical Service

Mr. GRAHAM WHITE asked the Minister of Health the number of insured persons, men and women, respectively submitted during 1935 to regional medical officers for incapacity references; and the results of their submissions.—Sir KINGSLEY WOOD replied: The particulars of incapacity references of insured persons to regional medical officers in England and Wales in 1935 are as set out below:—

	Men.	Women.
Total references dealt with .. .. .	178,917	297,921
Persons examined .. .. .	97,055	154,139
Persons found on examination to be incapable of work .. .. .	75,668	104,353
Persons found on examination to be not incapable of work .. .. .	21,387	49,786
Persons whose incapacity was accepted, so that examination was not necessary .. .. .	8,850	13,628
Persons not attending for examination although fit to do so (ordinarily these persons had been declared by their doctors to have become fit for work) .. .. .	73,012	130,154

#### Cost of Drugs and Medicines in Lancashire

Mr. RHYS DAVIES asked the Minister of Health whether he was aware that the drug and medicine costs covering the insured population under the care of the Lancashire insurance committee had increased, and that the average cost per insured person had increased from 19'30d. in 1916 to 41'21d. in 1934; and what steps, if any, his department was taking to stop this increase without at the same time depriving the insured population of necessities in this connexion.—Sir KINGSLEY WOOD replied: I am aware of the increase in the cost of drugs for insured persons which has occurred in Lancashire in common with other areas. As regards the second part of the question, action is taken under Article 42 of the Medical

Benefit Consolidated Regulations, 1928, which provides machinery for dealing with cases where the cost is in excess of what is reasonably necessary for the adequate treatment of the patients.

MONDAY, MAY 4TH

### Shropshire Quarry Workers and Silicosis

Mr. ARTHUR DUCKWORTH asked the Secretary for Mines whether he was satisfied that every possible precaution had now been taken to safeguard the barytes mines and quarry workers in the Pontesbury and Minsterley districts of Shropshire from the dangers of silicosis; and whether he was satisfied that the precautions were being duly enforced by His Majesty's inspectors of mines and were proving effective.—Captain CROOKSHANK replied: Following investigations by H.M. Inspectors of Mines, the best available precautions have been adopted at the barytes workings in this district and I hope that experience will show them to be effective. Necessarily the effective

application of the day-to-day precautions which are prescribed is largely in the hands of the management and the workmen themselves, but the inspectors also give the matter close attention whenever they visit the workings.

### Ventilation of the House of Commons

Mr. DAY asked the First Commissioner of Works whether his attention had been called to the system of air cooling and air conditioning installed in many large public buildings abroad; and if he would call for a report from his experts as to whether this system, if installed in the House of Commons, would improve the ventilation during the summer months.—Mr. ORMSBY-GORE replied: Yes, Sir. Investigations are being carried out by my engineers in collaboration with the Department of Scientific and Industrial Research, the Medical Research Council, and the Government Chemist, but the question is one of great difficulty on account of the age and character of the building.

## MEDICAL NEWS

### University of Oxford

On April 30th the degree of B.M. was conferred on C. D. Coode, R. A. Irving, and V. H. Yates.

On Tuesday last the regius professor of medicine introduced a statute to set up an institute of experimental psychology. Its establishment has been made possible by an anonymous gift of £10,000 and by the allocation of £500 from the Rockefeller trustees, together with £150 for the next five years. The first director will be Dr. William Brown.

Dr. Brown, who in 1921 succeeded Prof. William Macdougall as Wilde reader in mental philosophy, was born in 1881, and was educated at Collyer's School, Horsham, and at Christ Church. After a distinguished undergraduate career he became assistant master at Bradfield College and at St. Paul's School, meanwhile holding the John Locke scholarship at Oxford. In 1908 he was appointed head of the psychological department at King's College, and in 1914, having qualified in medicine from King's College Hospital, he was made reader in psychology in the University of London. Joining the Royal Army Medical Corps he acted as neurologist to the Fourth and Fifth Armies, B.E.F., from 1916, and in 1918 was given charge of the Craiglockhart War Hospital for Neuroasthenic Officers at Edinburgh. Later he joined the staff of Bethlem Hospital, and the neurological department at King's College Hospital, where he was appointed psychotherapist in 1925. Dr. Brown is a D.Sc. of London University, where he was Carpenter medallist in 1911, and he was elected F.R.C.P. Lond. in 1930. He has been sectional president of the British Association, and Terry lecturer at Yale, and is the author of well-known books on psychological subjects.

### University of Cambridge

On May 2nd the following degrees were conferred:—

M.D.—Sagarajasekaran Tyagaraja and John Gray.  
M.Chir.—R. V. Payne.  
M.B., B.Chir.—J. S. Richardson and J. R. Rosa.  
M.B.—M. K. Martyn.  
B.Chir.—Fenton Braithwaite.

\* By proxy.

Dr. M. T. Greig has been appointed university demonstrator in the department of anatomy for three years. Sir Walter Langdon-Brown, who retired from the regius professorship of physic in October, has been re-elected a fellow of Corpus Christi College.

Dr. J. S. Mitchell has been elected into a fellowship at St. John's College.

### Royal College of Physicians of London

At a meeting of the college held on April 30th, with Lord Dawson, the president, in the chair, the following members were elected fellows:—

Frederick William Price, M.D. Edin. (London); Harold Campbell Parsons, M.D. Toronto (Toronto); James Clark, M.D. Aberd. (Sheffield); Otto May, M.D. Camb. (London); Henry Charles Gustave Semon, M.D. Oxon. (London); Harold Black, M.D. Belf. (Birmingham); Henry Owen West, M.D. Lond. (London); Eric Wordley, M.D. Camb. (Plymouth); Dorothy Christian Hare, M.D. Lond. (London); Charles Brehmer Heald, M.D. Camb. (London); Arthur Hillyard Holmes, M.D. Manch. (Manchester); Charles Titterton Maitland, M.D. Lond. (London); Brevet-Col. Robert Cecil Priest, M.D. Camb. (R.A.M.C., Egypt); Lawrence Paul Garrod, M.D. Camb. (London); Kenneth Harry Tallerman, M.D. Camb. (London); Redvers Nowell Ironside, M.B. Aberd. (London); Reginald Cyril Lightwood, M.D. Lond. (London); Lieut.-Col. Ambuj Nath Bose, M.B. Calcutta (I.M.S.); William Innes Gerrard, M.D. Aberd. (Hong-Kong); Ernest Bulmer, M.D. Edin. (Birmingham); John Thornton Ingram, M.D. Lond.

(Leeds); Philip Montagu D'Arcy Hart, M.D. Camb. (London); Eric Alfred Blake Pritchard, M.D. Camb. (London); Major Sohan Lal Bhatia, M.D. Camb. (I.M.S. Bombay); Joseph Tegar Lewis, M.D. Belf. (Belfast); Charles Paton Blacker, M.D. Oxon. (London); Edwin Charles Warner, M.D. Lond. (London); John Greenwood Wilson, M.D. Lond. (Cardiff); William Hofmeyr Craib, M.D. Camb. (Johannesburg); Charles Bruce Perry, M.D. Bristol (Bristol); Eric Newmarch Allott, M.B. Oxon. (London); Hector Kenneth Goadby, M.D. Camb. (London); Leonard Findlay, M.D. Glasg. (London); John Gordon Thomson, M.B. Edin. (London); Derek Ernest Denny-Brown, M.B. N.Z. (London); and under Bye-law XXXVIII. (b), Sir Frederick Grant Banting, M.B. Kingston (Toronto); Henry Havelock Ellis, L.S.A. (London); and Robert Thomson Leiper, M.D. Glasg. (London).

The following were admitted members of the college:—

Douglas Anderson, M.B. Sydney; Charles Gaffney Baker, M.B. Lond.; Bawa Ishar Singh Bhalla, M.B. Punjab; Edward Eric Keith Bottomley, M.B. Melb.; Surg.-Lieut. Comdr. Thomas Latimer Cleave, L.R.C.P. Lond.; Maurice Coke, L.R.C.P. Lond.; Arthur Claud Ely Cole, M.B. Camb.; Joseph Doupe, M.D. Manitoab; John Ewart Edson, M.B. Sheff.; Thomas Russell Cumming Fraser, M.B. N.Z.; Rupert Montgomery Gordon, M.D. Dubl.; Isaac Henry Gosset, B.M. Oxon., L.R.C.P. Lond.; Cedric Culy Harvey, M.B. Lond., L.R.C.P. Lond.; Robert Roger Henderson, M.B. Lond.; David Elvet Vaughan Jones, M.D. Lond.; Harold Witcomb Everley Jones, M.B. Lond.; Brian McArdle, M.B. Lond.; Laurence Cleveland Martin, M.B. Camb.; Ivy May Massick, M.B. Punjab; Kenneth Sibley May, M.D. Lond.; Maurice Henry Pappworth, M.B. Liverp.; Clifford Gregory Parsons, M.B. Camb.; John Erskine Grayhurst Pearson, M.B. Oxon.; David Shaw, M.D. Lond.; William Fletcher Shaw, M.D. Manch.; Roy McKenzie Stewart, M.D. Edin.; Tryambak Hari Tulpule, M.B. Bombay; and John Michael Vaizey, M.B. Camb.

Licences to practise were conferred upon 171 candidates (156 men and 15 women) who have passed the final examination of the Conjoint Board and have complied with the by-laws of the college. The following are the names and the medical schools of the successful candidates:—

Subrahmanyam Alankaram, Madras and West Lond.; G. A. Armstrong, Westminster; J. D. F. Armstrong, St. Mary's; G. H. Baines, Camb. and St. Thos.; H. C. W. Baker, Liverp.; D. R. Balcombe-Brown, Oxon. and St. Thos.; S. Ball, Liverp.; J. M. Barnes, Camb. and Sheff.; G. S. Barradell-Smith, Middlesex; R. H. Barrett, St. Bart.'s; E. A. Beet, Middlesex; E. D. Belbin, Sheff.; A. M. Best, King's Coll.; J. F. Bostock, St. Bart.'s; C. M. Bowker, St. George's; J. D. Bradley-Watson and R. F. Braithwaite, St. Bart.'s; R. H. W. Britton, St. Thos.; J. M. Brown, Guy's; J. W. F. Brown, St. Thos.; I. S. Buchanan, Westminster; S. C. Buck, Camb. and Lond.; G. D. Channell, Guy's; S. H. C. Clarke, St. Bart.'s; J. W. Clegg, Guy's; J. C. Coates, Leeds; B. Cohen, Middlesex; J. O. Collin, Camb. and Westminster; Ellen M. T. Colls, Royal Free; J. O. Creighton, St. Thos.; J. W. Crofton, Camb. and St. Thos.; Nuala F. T. Crowley, Royal Free; S. Curwen, Middlesex; B. K. Das Gupta, Calcutta and West Lond.; S. K. Das Gupta, Calcutta and Lond.; H. K. Dastur, St. Bart.'s; L. E. C. Davies, Oxon. and St. George's; W. H. Davies, Cardiff; F. C. Deller, Liverp.; Hilda S. F. de Peyer, King's Coll.; P. A. Diemer, St. Mary's; H. G. Dowler, Camb. and Middlesex; T. P. Eddy, Oxon. and Middlesex; P. Emmerson, Durh.; C. H. C. Ferguson, Camb. and St. Thos.; J. P. Fox, Westminster; W. G. France, Leeds; Joan R. Franklin, Royal Free; O. M. Galal, Cairo and Birm.; R. E. Gibson, St. Bart.'s; D. L. H. Goddard and P. W. D. Goddard, St. Thos.; J. B. H. Green, Oxon. and St. Thos.; Eileen P. Gretton-Watson, Camb. and King's Coll.; J. A. T. Griffiths, Guy's; A. B. Hamer, Manch.; M. S. B. A. Hamid, Singapore; K. H. Harper, St. Bart.'s; E. W. Hart, Camb. and Middlesex; G. A. Hart, St. Thos.; L. Heasman and L. Henig, St. Bart.'s; G. E. Hesketh, Liverp.; J. F. Heslop, Manch.; M. C. B. Heyns, Cape and Univ. Coll.; J. D. N. Hill, St. Thos.; W. A. T. Hill,

Liverp.; R. A. Hoey, St. Thos.; L. R. Holt, Middlesex; A. C. Houghton, Birm.; O. Hughes, Guy's; K. F. Hulbert and G. A. Jackson, Middlesex; T. G. S. James, Camb. and King's Coll.; J. A. R. Johnson, Birm.; P. P. Jonescu, Jassy and St. Bart.'s; W. H. Jopling, St. Bart.'s; H. Josephs, King's Coll. and Westminster; L. B. Joshi, Bombay and Birm.; M. A. Kader, Leeds; L. U. Kamm, Guy's; D. D. Keall, Camb. and St. Thos.; R. G. M. Keeling, Camb. and St. Mary's; W. W. B. Kelly-Wiseman, Middlesex; D. Kendall, Oxon. and St. Thos.; B. S. Kent, Middlesex; W. E. Kershaw, Manch.; D. N. Leiberman, Leeds; S. A. H. Lesser, Camb. and St. Bart.'s; D. G. Lewis, Camb. and St. Thos.; S. W. Longthorne, King's Coll. and Charing Cross; A. A. Lovell, Cardiff and Birm.; C. R. Lowe, Birm.; G. Lowe, Liverp.; D. H. G. MacQuaide, St. Thos.; E. B. P. Madden, Charing Cross; J. A. Mansi, St. Bart.'s; M. S. Marks, Glasg. and Prince of Wales Hosp.; K. H. A. Marshall, Oxon. and St. Mary's; J. Mason, Cardiff and Middlesex; L. A. B. Matthews, Calcutta and St. Mary's; W. V. Maughan, Middlesex; N. E. Mawby, Liverp.; H. K. Meller, Camb. and Middlesex; G. D. N. Milne, Guy's; J. S. Minett, Camb. and St. George's; D. C. Moore, Manch. and Liverp.; J. T. Murray-Aynsley, Camb. and St. Thos.; Alice L. Musgrave, Royal Free; R. T. K. Nayar, Madras; Lucy M. B. Nelson, Royal Free; J. H. L. Newnham, Lond.; W. S. A. Onkes, Leeds; K. J. O'Connor, Manch. and West. Lond.; Sushila N. Paranjpe, Royal Free; J. W. Parks, St. Bart.'s; B. G. Parsons-Smith, and W. J. E. Phillips, Camb. and St. George's; J. W. Pierce, St. Thos.; G. C. L. Pile, Camb. and Middlesex; F. E. Pitt-Payne, Guy's; Faith C. Poles, Univ. Coll.; E. D. Pond, Charing Cross; Lena F. G. Priestman, Royal Free; J. M. Ranking, Camb. and St. Thos.; E. W. Rees, St. Thos.; A. Reeves, Leeds; A. H. M. Richards, Oxon. and St. Thos.; Gwen Richards, Royal Free; Lily Rivlin, Univ. Coll.; J. L. D. Roberts, St. Bart.'s; W. W. Roberts, Sheff.; S. Rosof, St. Mary's; G. R. Royston and D. M. Samuel, St. Bart.'s; S. H. Samuel, Leeds; J. W. R. Sarkies, St. Thos.; M. Schalat, Lond.; G. E. B. Scott, Univ. Coll.; Mary Scott, Royal Free; D. R. Seaton, Camb. and Leeds; R. G. Silver, Oxon. and Middlesex; M. R. Singh, Madras and Middlesex; C. H. Smith, Madras and West Lond.; G. C. Smith, Camb. and St. Thos.; H. P. R. Smith, Camb. and Lond.; J. I. M. Smith, King's Coll. and North Staffs. Inf.; Edith M. Spencer, Univ. Coll.; A. H. M.-K. Tabatabai, Birm.; A. K. Talwalkar, Bombay; G. K. Taylor, Lond.; R. D. Teare, St. George's; O. H. J. M. Telling, Oxon. and Leeds; S. F. Thomas, Lond.; R. M. Thornton, St. Thos.; P. H. Tooley, Lond.; R. F. Townsend, King's Coll. and Westminster; E. G. Tuckwell, Oxon. and St. Bart.'s; T. A. Turnbull, Guy's; J. R. T. Turner, Camb. and St. George's; G. A. van Someren, Middlesex; G. G. Waldin, St. Bart.'s; C. P. Warren, Lond.; H. Weiner, and A. M. Williams, St. Bart.'s; H. T. H. Wilson, Camb. and Middlesex; J. R. Wilson, King's Coll.; P. R. Wilson, Camb. and Lond.; A. W. Wragg, and P. J. M. Wright, St. Thos.; and C. A. Young, St. Mary's.

The following diplomas were conferred, jointly with the Royal College of Surgeons:—

*D.T.M. & H.*—J. K. Adranvala, H. A. Al-Farouki, A. G. W. Branch, E. J. Bury, R. Calderwood, G. J. Carr, B. K. P. Choudhury, R. L. Crook, J. G. Dickson, R. C. Dolly, E. Farrell, E. A. Fernando, W. A. Fitzherbert, H. C. Foster, A. F. Fowler, R. R. Gharekhan, D. A. B. Hopkin, S. H. O. Jones, O. Khairat, A. G. Kulkarni, E. A. Lawrence, G. K. Lim, J. B. Lobo, G. W. McAleer, J. S. McGregor, Oonunniamma Matthai, H. Most, K. C. Priddy, E. G. Pyne, S. Rajendram, M. S. Rao, J. D. Reid, W. H. Schokman, P. B. E. Senewiratne, M. J. Shah, Violet R. Sharp, D. A. Smith, D. S. Smith, J. R. C. Spicer, M. Theodoulou, V. Thorne-Thorne, S. R. Verma, Tatjana von Haebler, and E. L. Wickremeratno.

*D.O.M.S.*—F. Badrock, P. N. Chaudhuri, J. E. Clark, T. K. Clifford, S. P. Divatia, G. B. Ebbage, W. H. V. D. Ferdinands, F. Heckford, T. J. Howell, H. A. Ibrahim, F. J. Jensen, A. de B. Joyce, J. Mazell, B. F. Moore, S. Nath, T. Nath, G. Pollock, E. P. Tulloh, N. Wren, and E. C. Zorab.

*D.C.H.*—Cecile H. D. Asher, L. I. S. Campbell, E. H. Capel, M. Carr, Anne A. Craig, R. H. Fish, Margaret L. Foxwell, S. C. Gawne, Constance M. Hall, Irene M. Holoran, A. H. Khan, H. L. Lee, B. F. Longbotham, W. H. Patterson, Margaret R. Price, C. K. Rowan-Legge, W. I. D. Scott, J. M. Watt, and R. A. Wilson.

Lord Dawson was re-elected as representative of the college on the governing body of the British Postgraduate Medical School. Sir Bernard Spilsbury will deliver the Croonian lectures on the Doctrine of Inflammation at 5 o'clock at the college on May 19th, 21st, and 26th.

#### Notification of Manganese Poisoning

The Home Secretary proposes, after the expiration of forty days from May 4th, to make an order requiring that all cases of manganese poisoning occurring in factories or workshops shall be reported to inspectors of factories and certifying surgeons.

#### Industrial Health Education Society

The annual meeting of this society will be held on Wednesday next, May 13th, at 5 p.m., at 29, Portman-square, London, W.C., on the invitation of Lord Luke (the chairman) and Lady Luke. Sir Kingsley Wood, M.P., Minister of Health, and Mr. George Hicks, M.P., will be among the speakers. The hon. secretary is Dr. G. Clark Trotter, and the office is at Tavistock House North, Tavistock-square, W.C. 1.

#### Medical Research Council Travelling Fellowships

The Council invite applications for the following travelling fellowships for the academic year 1936-37:—

(1) In *Medical Science (including Clinical Medicine and Surgery)*.—Two or more fellowships to be awarded by the Council, and one Leverhulme fellowship, to be awarded on the nomination of the Council.

(2) In *Tuberculosis*.—Dorothy Temple Cross research fellowships (up to four).

(3) In *Psychiatry and Neurology (including Neurosurgery)*.

Candidates who are eligible under the second and third heads will as a rule not be considered under the first head. Completed applications must be lodged by June 1st, 1936. The awards will be made to suitably qualified British subjects of either sex, who have had some training in research work in the medical sciences and are likely to profit by a period of work at a university or other approved centre in another country before taking up positions for higher teaching or research in the United Kingdom. Fellowships under the first and second heads will each carry a stipend of £400 with an expenses allowance in addition. Fellowships under the third head are subject to different regulations but are of approximately equivalent total value. Inquiries for further information and forms of application should state the type of fellowship sought, and should be addressed to the secretary, Medical Research Council, 38, Old Queen-street, Westminster, London, S.W. 1.

#### London Hospital Medical College

Sir William Bragg, O.M., president of the Royal Society will distribute prizes to successful students at this school on Friday, June 26th, at 3 p.m.

#### Glasgow University Club, London

This club will dine at the Trocadero Restaurant, Piccadilly, W., on Friday, May 29th, at 7.15 for 7.30 p.m., when Mr. Ramsay MacDonald will take the chair. Any Glasgow University men who, though not members of the club, desire to attend are asked to communicate with the honorary secretaries, 62, Harley House, London, N.W. 1.

#### Invalid Children's Aid Association

The annual meeting of this association will be held at Norfolk House, 31, St. James's-square, London, S.W., at 3 p.m. on Tuesday next, May 12th. The Archbishop of Westminster will preside and the speakers will include Sir Kingsley Wood, Minister of Health, Sir Maurice Cassidy, and Mr. H. S. Souttar.

#### West Kent Medico-Chirurgical Society

The annual dinner of this society will be held at Chiesman Restaurant, Lewisham, S.E., on Thursday, May 14th, at 7.30 for 8 p.m. Dr. J. R. Wylie, the president, will be in the chair. The hon. secretary of the society is Dr. C. J. B. Buchan, 267, Baring-road, Grove Park, London, S.E. 12.

#### British Red Cross Society

Red Cross Day will be held on the anniversary of Florence Nightingale's birthday, Tuesday, May 12th, when funds will be collected in aid of the work of the British Red Cross Society. This includes the maintenance of ambulances and first-aid stations, clinics for rheumatism and orthopaedic clinics, an organisation for blood transfusion, and dispensaries for hop-pickers and herring-fishers, while the society is also taking part in plans to mitigate the consequences of air raids, and has sent two units to Abyssinia for the relief of Ethiopian sick and disabled.

#### Vanishing Fauna of Africa

In a lecture delivered at King's College last Monday under the auspices of the University of London Animal Welfare Society Dr. A. H. B. Kirkman spoke of the rapid extermination of the African fauna and the failure of the Colonial Office to establish sanctuaries or national parks. The Kruger National Park of South Africa and the Parc National Albert of the Congo were the only reserves that could not be abolished by a stroke of the pen. The London Convention of 1933, though nominally operative, would have no pronounced results for a long time to come.

## OBITUARY

**ALBERT CARLESS, C.B.E., M.S. Lond.,  
F.R.C.S. Eng.**

THE death occurred suddenly at Worthing on April 27th of Mr. Albert Carless, consulting surgeon to King's College Hospital and known by name to the whole medical world through the famous manual of surgery, colloquially known as "Rose and Carless."

Albert Carless, who was born at Richmond in 1863, received his early education at King's College School and joined the medical school at King's College Hospital in 1881. He was a successful student, winning medals and scholarships, among others the Warneford and Leathes prize, and graduated as

M.B. Lond. with honours in 1886, as B.S. in 1887, and in the following year as M.S., taking also the diploma of F.R.C.S. Eng. He held the house appointments at King's College Hospital, having the distinction of dressing for Lister, was appointed surgical registrar, and duly became assistant surgeon to the hospital and teacher of clinical and operative surgery. In 1898 he became full surgeon to the hospital and in that year appeared the first edition of the

MR. CARLESS

[Photograph by Elliott and Fry]

famous "Manual of Surgery" of which he was the joint author with the late William Rose. Prof. Rose's share in the production was that of supervision; the work was entirely written by Carless and was the outcome of his splendid teaching classes. It was translated into Hungarian, Chinese, and Arabic, and American editions were also published.

Mr. C. P. G. Wakeley writes: "As a teacher, Carless was a stimulating and fluent exponent of the art of surgery, and probably no one had a bigger class following him round the wards of the old King's College Hospital, in Lincoln's Inn Fields. In fact, some dressers frequently complained that they rarely could get near the patient when Carless was doing a teaching round, for often he had some sixty to eighty fellowship students accompanying him round the wards. These men were drawn from the other London hospitals and from the Dominions. Carless had that adaptability for teaching which made him outstanding, for it did not matter whether the patient was a vague abdominal case with few symptoms, or a classical example of a cancer, he made it interesting and could teach for an hour or more in that lucid and compelling manner, which, for many a student, facilitated his passing the higher examinations in surgery.

The 'Manual of Surgery,' which Carless wrote and published in 1898, was in reality a combination of the notes which he had made during his coaching and teaching of advanced surgical students. Prof. Rose's name was added to the volume rather as an appreciation by Carless of what he had received

from one of his earlier teachers." But the senior to whom Carless owed most was Lister, to whom when on the hospital staff he acted as assistant surgeon. Thus he had seen the whole antiseptic technique develop. As a surgeon he was careful, thoughtful, and a rapid operator, being able to put into practice the results of his own orderly demonstrations to many mixed classes. He was devoted to King's College Hospital to which he always gave unstintingly the major portion of his time, but he was on the staff also of the Seamen's Hospital at Greenwich and of several other institutions, and wherever he worked his outstanding characteristics of clinical skill and thoughtfulness for the patient were manifest.

During the war Carless served first with the rank of major as surgeon to the London Hospital, Territorial, 1914-16; later he became consulting surgeon to the Eastern Command, and at the close of hostilities he was promoted to the rank of colonel and received the C.B.E. Throughout the period of the war he held the position of professor of surgery in King's College, a position in which he had succeeded Sir Watson Cheyne in 1902. He resigned from the honorary staff of King's College Hospital in 1919, and was appointed consulting surgeon. There can be no doubt that these strenuous duties, coupled with the loss of two sons in the war, were the factors responsible for his early retirement from the staff.

From an early period in his professional life Carless had been deeply interested in religious and social work, and when he retired from King's College Hospital several years before his time on the staff was completed it was due to a desire to devote himself to philanthropic aims. He was medical director of Dr. Barnardo's Homes, in which capacity he travelled round the world more than once and visited most countries. There can be no doubt that the good influence which he imparted was tremendously appreciated by that ever-growing institution. After devoting himself for some five years to this and similar labour, he retired to Crieff, where he made his Scottish home. He has left behind him a great reputation as teacher, surgeon, and philanthropist; throughout his busy and varied life he was consistent in his obedience to deep religious convictions and in his desire to ameliorate human troubles.

**CECIL JOHN ROGERSON, M.C., M.B. Lond.**

Dr. Cecil John Rogerson, who died recently at the untimely age of 49, had a fine career. His parents lived in Lewes, where he spent his boyhood, and he received his general education at Brighton. He went to University College Hospital, graduated as M.B., B.S. in 1909, and then served the resident appointments at the Leicester Royal Infirmary. On the outbreak of war he joined up immediately and distinguished himself for his courage and devotion to duty. He was awarded the Military Cross for attending the wounded under fire and reached the rank of lieutenant-colonel, R.A.M.C. He had a narrow escape of being killed on Armistice Day, for just before eleven o'clock a German shell exploded by his side and killed several who were standing near him. After the war he was appointed to the Kent and Canterbury Hospital as physician and became recognised also as a skilful anaesthetist. In general practice, where he was the partner of Dr. H. O. Preston, he was highly successful. Though privately rather a difficult man to approach, being reticent

and reserved, in his 16 years in Canterbury as a general practitioner he was a complete success. He was able and conscientious, popular with his patients, and regarded with particular affection by many. He was a good obstetrician and gynaecologist with a special affection for children, which his little patients returned. He was a physically delicate man, and broke down in health some two years ago, but seemed to have made a good recovery. A few weeks before his death he failed again and entered a sanatorium where his condition gave rise to anxiety, but the end was unexpected. Rogerson was an enthusiastic sportsman, had been a useful bowler as a member of the local cricket club, and played golf and tennis with equal keenness. He was unmarried.

#### ALFRED ERNEST PAYNE, M.B. Lond.

Dr. Alfred Ernest Payne, who died on April 7th, was born in Leicester, received his general education at Wyggeston School, Leicester, and his medical training at St. Mary's Hospital. He was a successful student, entered St. Mary's as a natural science scholar, gained prizes in several preliminary subjects, and became prosector of anatomy in the school. He graduated as M.B. Lond. in 1898 and was for a time assistant demonstrator of anatomy at St. Mary's Hospital. After short service with a steamship company he started general practice in Leicester, but during the war he developed an interest in radiology, derived from his skilled practice of photography, and he was attached to the 5th Northern General Hospital as radiologist. After the war he did not return to general practice but specialised in radiology and in this capacity won high repute in and beyond his locality. He became radiologist to the Leicester Pensions Hospital and Institute of Diseases of the Skin, and to the Loughborough General Hospital, and at the time of his death was honorary consulting radiologist and director of the department at Leicester Royal Infirmary. He had been a vice-president of the special section of the Royal Society of Medicine, and in 1921 was president of the Leicester Medical Society. He married Lillie, daughter of Dr. C. A. Schneider, and was 60 years old at the time of his death.

#### J. G. CATTANACH, M.D., F.R.C.P. Edin.

The death occurred in Edinburgh on April 28th of Dr. J. G. Cattanach at the age of 84; he had been for many years closely associated with the medical life of Edinburgh. He graduated with distinction at Edinburgh University in 1893 and was an original life member of the Students' Union. He was a resident at the Royal Infirmary and was a fellow and president of the Royal Medical Society. He became a fellow of the Royal College of Physicians, Edinburgh, in 1898, and was for a time assistant physician to the Deaconess Hospital. He was appointed assistant to the professor of medicine in Edinburgh University, a post which he held for many years, and in that capacity his genial personality is well-remembered by many graduates.

Dr. Cattanach was a man of many interests. In his younger days he was a keen sportsman, an enthusiastic golfer and angler, and a fine shot. He had, moreover, an extensive knowledge of Scottish life and letters. He was proud of belonging to a Highland family, and took a pride in the fact that at one time he had been a piper in the London Scottish. He was a prominent member of the Scottish Arts Club, the Pen and Pencil Club, and of the Monks of St. Giles. He served with the rank

of Captain in the R.A.M.C. (Territorials), and was a justice of the peace. He is survived by two daughters.

## Medical Diary

### SOCIETIES

- ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**  
**TUESDAY, May 12th.**  
*Therapeutics and Pharmacology.* 5 P.M. Annual General Meeting. Prof. J. H. Gaddum: Estimation of Histamine in Blood. Mr. R. Wein: Effect of Diet on Resistance to Drugs.  
*Psychiatry.* 8.30 P.M. Annual General Meeting. Dr. E. Guttman: Psychiatric Observations in Arterial Hypertension. Dr. R. F. Barbour: Bromide Intoxication. Dr. W. Mayer-Gross: Optic Impairment in Constructional Apraxia.
- WEDNESDAY.**  
*Surgery: Subsection of Proctology.* 5 P.M. Annual General Meeting. Dr. R. Bensaude, Dr. Marshall Findlay, Dr. P. H. Manson-Bahr, and Mr. J. P. Lockhart-Mummery: The Aetiology and Treatment of Fibrous Stricture of the Rectum (including Lymphogranuloma Inguinale).
- FRIDAY.**  
*Obstetrics and Gynaecology.* 8 P.M. Annual General Meeting. Mr. Frederick Roques, Mr. Arnold Walker, Dr. A. J. Wrigley, Dr. Herbert R. Spencer, and Mr. James Wyatt: That Induction of Premature Labour should not Play any Part in the Treatment of Pelvic Contraction or Disproportion in Primigravidae. Mr. Everard Williams, Dr. G. W. Theobald, Mr. Hastings Ince will also speak.  
*Radiology.* 7 P.M. Annual General Meeting.
- SATURDAY.**  
*History of Medicine.* Meeting at Bath. 2.45 P.M. Demonstration of Bathing Establishments. 9.30 P.M., Dr. F. G. Thomson: Some Early Physicians at Bath and the Times they Lived in.
- SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thornhaugh-street, W.C.**  
**FRIDAY, May 15th.—5 P.M., Prof. W. W. Jameson and Prof. R. M. F. Picken: Post-graduate Teaching in Public Health.**
- SOUTH-WEST LONDON MEDICAL SOCIETY.**  
**WEDNESDAY, May 13th.—9 P.M. (Bolingbroke Hospital, Wandsworth Common, S.W.), Mr. H. Samuelli and Dr. C. O. Hawthorne: Voluntary Euthanasia.**
- MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.**  
**MONDAY, May 11th.—8 P.M., Annual General Meeting. 8.30 P.M., Sir James Walton: Carcinoma of the Stomach. (Annual Oration.) A Conversazione will follow.**
- HARVEIAN SOCIETY OF LONDON.**  
**THURSDAY, May 14th.—8.30 P.M. (Manson House, 26, Portland-place, W.), Dr. Basil Parsons-Smith: Angina Pectoris.**
- SOCIETY OF RADIOTHERAPISTS.**  
**FRIDAY, May 15th.—4.30 P.M. (11, Chandos-street, W.), Mr. G. F. Stebbing and Miss Margaret Tod: Technique and Results of the Radiation Treatment of Carcinoma of the Rectum.**
- NORTH-WEST LONDON MEDICAL SOCIETY.**  
**TUESDAY, May 12th.—9 P.M. (Stroud Laboratories, National Cancer Research Fund, The Ridgeway, Mill Hill, N.W.), Dr. W. E. Gye: Recent Advances in Cancer Research.**
- PADDINGTON MEDICAL SOCIETY.**  
**TUESDAY, May 12th.—9 P.M. (St. Mary's Hospital, W.), Dr. James Menzell: Diagnosis and Treatment of some Common Conditions for which Manipulative Treatment is Required.**
- TUBERCULOSIS ASSOCIATION.**  
**FRIDAY, May 15th.—5.15 P.M. (Manson House, 26, Portland-place, W.), Sir Leonard Rogers, Dr. Andrew Morland, and Dr. Basil Price: Climate and its Relationship to Tuberculosis. 8.15 P.M., Mr. J. E. H. Roberts and Dr. F. G. Chandler: Recent Advances in Thoracoscopy and Adhesion Section.**
- BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck-street, W.**  
**THURSDAY, May 14th.—6.30 P.M., Annual General Meeting. FRIDAY.—11 A.M., Visit to the Radium Institute, 16, Riding House-street, W. 5 P.M., Case Demonstration and Discussion.**
- MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.**  
**THURSDAY, May 14th.—8.30 P.M. (11, Chandos-street, W.), Dr. Emmanuel Miller: The Limits of Psychopathology.**
- ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.**  
**WEDNESDAY, May 13th, and THURSDAY.—Meeting at Glasgow. On Thursday, at 2.30 P.M., Symposium on Somnifaine.**
- LECTURES, ADDRESSES, DEMONSTRATIONS, &c.**
- UNIVERSITY OF LONDON.**  
**TUESDAY, May 12th, WEDNESDAY, and THURSDAY.—5.30 P.M. (17, Bloomsbury-square, W.C.), Prof. Arthur Stoll (Basle): Cardiac Glucosides.**  
**FRIDAY.—5 P.M. (King's College, Strand, W.C.), Prof. Henri Fredericq (Liège): The Laws of Excitation of the Autonomic Nervous Systems.**

**INTERNATIONAL CONGRESS OF PHYSICAL MEDICINE.**  
TUESDAY, May 12th, to SATURDAY, at the Hotel Great Central, Marylebone-road, N.W., and elsewhere.

**BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.**  
MONDAY, May 11th.—2.15 P.M., Dr. Duncan White: Radiological Demonstration. 3.30 P.M., Dr. Wilfred Shaw: Irregular Uterine Hæmorrhage.  
TUESDAY.—2 P.M., Prof. E. H. Kettle: Pathological Demonstration. 3 P.M., Mr. Earl King, Ph.D.: Phosphatase as a Test of Hepatic Function.  
WEDNESDAY.—Noon, clinical and pathological conference (medical). 2.30 P.M., clinical and pathological conference (surgical).  
THURSDAY.—2.30 P.M., Dr. W. S. C. Copeman: Arthritis. 2.30 P.M., Sir Henry Gauvain: Surgical Tuberculosis. 3 P.M., Operative Obstetrics.  
FRIDAY.—2.15 P.M., Dr. A. A. Davis: Gynæcological Pathology.  
Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetric and gynecological clinics or operations, refresher course for general practitioners.

**FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**  
MONDAY, May 11th, to SUNDAY, May 17th.—BROMPTON HOSPITAL, S.W. All-day course in thoracic surgery.—ST. JOHN'S HOSPITAL, Lisle-street, W.C. Afternoon course in dermatology.—MAUDSLEY HOSPITAL, Denmark-hill, S.E. Afternoon course in psychological medicine.—CANCER HOSPITAL, S.W. Sat. and Sun., course in general surgery.—Courses are open only to Members of the Fellowship.

**LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.**  
MONDAY, May 11th.—5 P.M., Dr. W. N. Goldsmith: Acneiform Eruptions.  
TUESDAY.—5 P.M., Dr. H. C. G. Semon: Diseases of the Buccal Mucous Membrane.  
THURSDAY.—5 P.M., Dr. A. C. Roxburgh: Eczema.  
FRIDAY.—5 P.M., Dr. W. Griffith: Bullous Eruptions.

**HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.**  
WEDNESDAY, May 13th.—2 P.M., Sir Lancelot Barrington-Ward: Hirschsprung's Disease. 3 P.M., Lecture—Dr. W. W. Payne: Food Values: Normal and Special Diets.  
Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.

**UNIVERSITY OF BIRMINGHAM.**  
TUESDAY, May 12th.—3.30 P.M. (General Hospital), Mr. B. T. Rose: Principles and Practice of Radio-surgery.  
THURSDAY.—4 P.M. (Medical Faculty Buildings), Prof. W. W. C. Topley, F.R.S.: The Practical Application of Antigen-Antibody Mechanisms in Diagnosis, Prophylaxis and Treatment. (William Withering Lecture).  
FRIDAY.—3.30 P.M. (Queen's Hospital), Dr. E. Baylis Ash: Psoriasis and Seborrhœa.

**MANCHESTER ROYAL INFIRMARY.**  
TUESDAY, May 12th.—4.15 P.M., Mr. E. D. Telford: Occlusive Disease of Peripheral Arteries.  
FRIDAY.—4.15 P.M., Mr. A. H. Southam: Demonstration of Surgical Cases.

**GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.**  
WEDNESDAY, May 13th.—4.15 P.M. (Victoria Infirmary), Dr. W. Herbert Brown: Occupational Dermatoses.

## Vacancies

For further information refer to the advertisement columns

**Accrington, Victoria Hospital.**—H.S. £150.  
**Barnsley, Beckett Hospital and Dispensary.**—Cas. O. and H.P. £250 and £200 respectively.  
**Belfast, Forster Green Hospital, Fortbreda.**—H.P. At rate of £150.  
**Birkenhead Education Committee.**—Asst. School M.O. £500.  
**Birmingham, Selly Oak Hospital.**—Temp. Res. Pathologist. 9 guineas weekly.  
**Bradford Royal Infirmary.**—H.P. At rate of £135.  
**Burton-on-Trent, Ereby Hall Orthopedic Hospital.**—Locum Res. Asst. M.O. At rate of £350.  
**Burton-on-Trent General Infirmary.**—H.P. and Cas. O. £150.  
**Cambridge, Addenbrooke's Hospital.**—Res. Surg. O. £225. Also H.P. At rate of £130.  
**Canterbury, Kent and Canterbury Hospital.**—Hon. Physician.  
**Cardiff, King Edward VII. Welsh National Memorial Association.**—Asst. Res. M.O. for Glan Ely Tuber. Hospital. £200.  
**Carshalton, Beadlington and Wallington Hospital.**—Three Hon. M.O.'s.  
**Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.**—Third Res. H.S. At rate of £75.  
**City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.**—Med. Reg.  
**Coventry and Warwickshire Hospital.**—Hon. Ophth. Surgeon.  
**Delamere, Cheshire, Crossley Sanatorium.**—Med. Supt. £650.  
**Derbyshire County Council.**—Asst. Maternity and Child Welfare M.O. £600.  
**Doncaster Royal Infirmary.**—H.S. £175.  
**Dreadnought Hospital, Greenwich, S.E.**—Receiving Room Officer. At rate of £200.  
**Durham County Council Education Department.**—Asst. School M.O. £500.  
**East Ham County Borough.**—Locum Tenens. £10 10s. weekly.  
**Epsom County Hospital.**—Res. Asst. M.O. At rate of £375.  
**Evelina Hospital for Sick Children, Southwark-street, S.E.**—H.P. At rate of £120.  
**Exeter, Devon Mental Hospital, Exminster.**—Jun. Asst. M.O. £350.  
**Fareham, Hants, Knowle Mental Hospital.**—Deputy Med. Supt. £700.  
**Gordon Hospital for Rectal Diseases, Vauxhall Bridge-road, S.W.**—Res. H.S. At rate of £150.  
**Guildford, Royal Surrey County Hospital.**—H.S. £150.  
**Hallifax Royal Infirmary.**—Third H.S. At rate of £150.  
**Holl, Norfolk, Kelling Sanatorium.**—Second Asst. Res. M.O. £350.  
**Hospital for Sick Children, Great Ormond-street, W.C.**—Res. H.P. and Res. H.S. Each at rate of £100.  
**Huddersfield Royal Infirmary.**—Res. Surg. O. £225—£250. Cas. O. £200. H.P. and Res. Anæsthetist. Also H.S. Each at rate of £150.  
**Hull Royal Infirmary.**—H.S. to Ophth. and Ear, Nose, and Throat Dept. At rate of £150. Also H.S. to Sutton Branch Hospital. At rate of £160.  
**Ipswich, East Suffolk and Ipswich Hospital.**—Orthopedic Surgeon. £500.  
**Islington Metropolitan Borough.**—Asst. M.O.H. £700.  
**Isolation Hospital, Muswell Hill, N.**—Res. M.O. £500.  
**Kettering and District General Hospital.**—Second Res. M.O. £125.  
**Kingston District Hospital.**—Res. Asst. M.O. At rate of £375.  
**Leeds General Infirmary.**—Reg. to Orthopedic Dept. £400.  
**Lincoln, Burton-road Hospital.**—Asst. M.O.H. £600.  
**Liverpool City.**—Temp. Jun. Asst. Bacteriologist. £400.  
**Liverpool, Fazakerly Sanatorium.**—Res. Asst. M.O. £200.  
**Liverpool Hahnemann Hospital.**—Hon. Asst. Ophth. S.  
**Liverpool University.**—Lecturer in Dept. of Bacteriology and Lecturer in Physiology. Each £600—£700. Also two Demonstrators. Each £300.  
**Llanclly and District Hospital.**—H.S. £150.  
**London Child Guidance Clinic, 1, Canonbury-place, N.**—Three Fellowships in Psychiatry. Each £300.  
**London County Council.**—Asst. M.O., Grade I. £350. Asst. M.O.'s, Grade II. Each £250. H.P. At rate of £120. Temp. Asst. M.O., Grade I. At rate of £350. Visiting M.O. £200. Also Temp. Dist. M.O. At rate of £150.  
**Macclesfield General Infirmary.**—Sen. H.S. At rate of £180.  
**Manchester, Ancoats Hospital.**—Combined H.S. (Aural) and H.P. Post. At rate of £100.  
**Manchester City.**—Vacancies on Consultant Medical, Surgical, &c. Staffs of Municipal Hospitals. £125—£400.  
**Manchester, Duchess of York Hospital for Babies.**—Med. Reg. £50.  
**Manchester Royal Children's Hospital, Pendlebury.**—Res. H.S. At rate of £100.  
**Manchester Royal Infirmary.**—Hon. Asst. Surgeon.  
**Manchester and Salford Hospital for Skin Diseases.**—Two Asst. M.O.'s. Each £100.  
**Miller General Hospital, Greenwich-road, S.E.**—Res. Surg. O. and Reg. £250. Cas. O. At rate of £150. Also two H.P.'s and H.S. Each at rate of £100.  
**Newcastle-upon-Tyne Hospital for Sick Children.**—Asst. Hon. Physician to Skin Dept.  
**Newport, Mon, Royal Gwent Hospital.**—H.S. and Asst. Cas. O. At rate of £135.  
**North Riding of Yorkshire C.C.**—County M.O.H. and School M.O. £1200.  
**Norwich, Norfolk and Norwich Hospital.**—H.S. to Spec. Depts. £120.  
**Nottingham Children's Hospital.**—Res. H.P. At rate of £150.  
**Oxford, The Warnford.**—Jun. Asst. M.O. £350.  
**Oxford, Wingfield-Morris Orthopedic Hospital, Headington.**—Lord Nuffield Scholarship in Orthopedic Surgery. £200.  
**Plymouth, Prince of Wales's Hospital, Greenbank-road.**—Res. Surg. O. At rate of £225.  
**Poplar Hospital for Accidents, East India Dock-road, E.**—Second Res. Officer. £175.  
**Preston and County of Lancaster Royal Infirmary.**—H.S. £150.  
**Princess Beatrice Hospital, Earl's Court, S.W.**—Res. M.O. At rate of £150.  
**Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.**—Res. M.O. for Isolation Hospital. At rate of £200. Res. Anæsthetist. At rate of £100. Res. Anæsthetist and Dist. Res. M.O. At rate of £90. Also Asst. Res. M.O. At rate of £80.  
**Raivenstall, Lancs, Moorlands Public Assistance Institution.**—Visiting Obstetrician. £100 and 3 gns. per session.  
**Redhill, Royal Earlswood Institution.**—Jun. Asst. M.O. At rate of £250.  
**Rochester, St. Bartholomew's Hospital.**—Res. Surg. O. At rate of £225.  
**Romford, Oldchurch Hospital.**—Asst. Res. Radiologist. £250.  
**Royal Cancer Hospital, Fulham-road, S.W.**—H.S. At rate of £100.  
**Royal Naval Medical Service.**—M.O.'s.  
**Royal Northern Hospital, Holloway, N.**—H.P. At rate of £70.  
**Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.**—H.P. At rate of £100.  
**St. John's Hospital, Lewisham, S.E.**—Hon. Ophth. Reg.  
**Seamen's Hospital Society, Greenwich.**—H.S. for Tilbury Hospital. At rate of £140.  
**Sheffield, Jessop Hospital for Women.**—Res. M.O. Also H.S. At rate of £150 and £100.  
**Sheffield Royal Infirmary.**—Ophth. H.S. At rate of £120.  
**Smethwick County Borough.**—Asst. M.O.H. and Asst. School M.O. £350.  
**Southeast-on-Sea General Hospital.**—H.S. for Spec. Depts. At rate of £100.  
**South Eastern Hospital for Children, Sydenham, S.E.**—Hon. Cons. Surgeon. Also Jun. Res. M.O. At rate of £100.  
**Stafford, Prestwood Sanatorium.**—Jun. Asst. M.O. £250.  
**Stockport Infirmary.**—H.S. and Cas. O. £150.  
**Taunton and Somerset Hospital.**—Sen. House M.O. At rate of £150.  
**Twickenham, St. John's Hospital.**—Hon. Cons. Physician.  
**University College Hospital, Gower-street, W.C.**—Hon. Asst. Surgeon.  
**Walsall County Borough.**—Asst. M.O.H. £350.

**Warwickshire and Coventry Mental Hospital.**—Med. Supt. £1200.  
**Wembley U.D.C.**—M.O.H. £1000.  
**West Bromwich, Hallam Hospital.**—Two H.P.'s and H.S. Each at rate of £200.  
**West London Hospital, Hammersmith, W.**—Res. Anaesthetist. At rate of £100.  
**Willesden General Hospital, Harlesden-road, N.W.**—Hon. Clin. Assts. for Out-patients' Dept.  
**Wolverhampton Royal Hospital.**—H.P. At rate of £125. Also H.S. At rate of £100.  
**Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.**—Hon. Asst. Obstet. Surgeon. Also two H.S.'s. Each at rate of £100.  
**Worthing Borough.**—Asst. M.O.H. £500.  
**York City.**—Asst. M.O.H. At rate of £350.  
**Zelland County.**—County M.O.H. £700.  
 The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Brecon (Brecknock) and Hoylake (Cheshire).

**TREVOR, DAVID, M.S. Lond., F.R.C.S. Eng.,** Hon. Assistant Orthopaedic Surgeon at the Royal Waterloo Hospital, London.  
**URQUHART, JAMES, M.B. Edin., D.P.H.,** Assistant Tuberculosis Officer at Winter-street Hospital, Sheffield.  
**Hampstead General and North-West London Hospital.**—The following appointments are announced:—  
**KREMER, MICHAEL, M.D., M.R.C.P. Lond.,** Physician to Out-patients;  
**PRYDE, N. W., M.B. N.Z.,** House Surgeon to a Surgical Unit; and  
**DAVIES, D. W., M.R.C.S. Eng.,** Casualty Medical Officer.  
 Certifying Surgeons under the Factory and Workshop Acts:  
**Dr. V. WILKINSON, M.C.** (Croydon District, Surrey);  
**Dr. W. B. BALLENDEN** (Pontesbury District, Salop);  
 and **Dr. T. MORGAN** (Swanscombe District, Kent).

## Births, Marriages, and Deaths

### BIRTHS

**CHITNIS.**—On May 1st, at Welbeck-street, W., the wife of Dr. C. N. Chitnis, of a son.  
**MATTHEWS.**—On April 27th, at Cowfold, Sussex, the wife of Dr. T. E. Matthews, of a daughter.  
**SLEIGH.**—On May 1st, at Dedham, Colchester, the wife of Dr. Graham Sleigh, of a daughter.

### MARRIAGES

**CLARKE—BLUNT.**—On April 20th, at Alexandria, Egypt, Major Ailwyn Clarke, M.C., R.A.M.C., to Cicely Blunt, second daughter of Mr. and Mrs. Graham Blunt of Streatham.  
**GARDNER—NIXON.**—On April 29th, at St. Mary-le-Tower Church, Ipswich, Surg. Lt.-Com. (D.) Andrew Allen Gardner, to Mary Barron, daughter of the late Mr. J. C. Nixon and of Mrs. Nixon of Ipswich.

### DEATHS

**BENNETT.**—On April 20th, at Westergate, Sussex, Cecil Bennett, M.R.C.S. Eng., Medical Superintendent, General Hospital, Shanghai.  
**BRASH.**—On April 29th, John Bardsley, M.R.C.S., L.R.C.P., of Handsworth, Birmingham.  
**BROWN.**—On May 1st, at Harrogate, James William Henry Brown, M.R.C.S. Eng., L.R.C.P. Edin., formerly of Holbeck and Roundhay, in his 77th year.  
**BURNETT.**—On April 25th, at Westcliff, John Duncan Burnett, M.B. Aberd., of Southchurch, Essex, and formerly of Watford, Hertfordshire.  
**COOKE.**—On May 4th, at Wootton, Isle of Wight, Reginald Torriano Cooke, M.R.C.S. Eng.  
**GODSON.**—On May 2nd, at Gatley, Ches., John Herbert Godson, M.B. Camb., D.P.H.  
**GRANGE.**—On April 29th, at Bournemouth, Wm. D'Oyly Grange, M.D. Edin., formerly of Moffat and Harrogate, aged 83.  
**JACKSON.**—On April 26th, suddenly, at Esher, John William Jackson, M.B. Glasg., late of Shanghai.  
**PATON.**—On April 29th, at Rugeley, Staffs, Benjamin Lewis Paton, O.B.E., M.D. Edin., aged 75.  
**WAIT.**—On April 26th, at Carlisle, John Alfred Wait, M.B. Camb., Lieut.-Col., T.D. (Retd.), Tyne mouth R.G.A.  
*N.B.—A fee of 1s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Appointments

**CLARK, E. B., M.B. Edin.,** has been appointed Medical Registrar to the Out-patient Department of Manchester Royal Infirmary.  
**CLAYE, A. M., M.D. Leeds, F.R.C.S. Eng.,** Hon. Surgeon to the Hospital for Women at Leeds.  
**CURRIE, D. W., M.D., Ch.M. Leeds, M.C.O.G.,** Hon. Obstetric Surgeon to the Leeds Maternity Hospital.  
**FOX, P. P., M.B. Liverp., D.P.H.,** Medical Officer of Health, School Medical Officer, and Port Medical Officer for Harwich.  
**GUTHRIE, SYLVIA K., M.D. Manch., M.R.C.P. Lond.,** Hon. Visiting Physician to the Duchess of York Hospital for Babies, Manchester.  
**HENDERSON, STANLEY, M.B. Liverp., M.C.O.G.,** Resident Obstetric Officer at Hope Hospital, Salford.  
**HERRON, R. A. C., M.B. Belf.,** Second Assistant Resident Medical Officer at the Southlands Hospital, Shoreham-by-Sea.  
**HISLOP, J. C., M.B. Edin.,** Senior Resident Medical Officer at the King Edward Memorial Hospital, Ealing.  
**JOHNSON, J. S., M.B. Durh., D.P.M.,** First Assistant Medical Officer at Durham County Mental Hospital, Winterton.  
**KELLY, G. C., M.D. Aberd., D.P.H.,** Senior Assistant Medical Officer of Health for Birmingham.  
**LIPSCHITZ, W., M.D. Freiburg, L.R.C.P. Edin.,** Assistant Medical Superintendent at the Royal Sea-Bathing Hospital, Margate.  
**MORGAN, VERNON, M.R.C.S. Eng.,** Hon. Anaesthetist to the Princess Beatrice Hospital, London.  
**NEWMAN, J. L., M.D. Camb., M.R.C.P. Lond., D.P.H.,** Assistant County Medical Officer of Health for West Sussex and Medical Officer of Health for the Midhurst Rural District.  
**OZANNE, R. C., M.B. Oxon.,** Hon. Physician to the Harrogate and District General Hospital.  
**PHELAN, KIERAN, M.B. Irel.,** Assistant Port Medical Officer of Health for Harwich.  
**SHARPEY-SCHAFFER, E. P., M.B. Camb., M.R.C.P. Lond.,** Resident Medical Officer at the National Hospital for Diseases of the Heart.  
**SHEPHERD, C. E. A., M.R.C.S. Eng., D.P.M.,** Medical Superintendent at the Kent County Mental Hospital, Chatham.  
**SMITHERS, DAVID, M.D. Camb.,** Out-patient Medical Officer at the National Hospital for Diseases of the Heart.

### Royal Institution

The annual meeting of the Royal Institution of Great Britain was held on May 1st. The report of the visitors, which was received and adopted, referred to the improved attendance at lectures, and stated that the recent Christmas juvenile lectures on photography had an average audience of over 500, while a Friday evening discourse by Sir James Jeans was attended by 640 people, the largest audience seen in the institution for many years. The legacy of Mr. Harry Brown, of Sergeant's Inn, is expected to amount to between £25,000 and £30,000, and to invest this money and provide for future expansion of research the managers have purchased the freehold of 19, Albemarle-street, immediately adjoining the premises of the institution. The reconstruction of the principal library is to be finished by the summer, and a large new research laboratory is being provided as a part of the scheme. By the issue of Volume VII. and a separate index the publication of Faraday's diary has been completed.

The officers for the ensuing year will be Lord Eustace Percy (president), Sir Robert Robertson (treasurer), and Major C. E. S. Phillips (secretary). The managers include Sir James Crichton-Browne, F.R.S., and Mr. V. Warren Low, and the visitors Prof. H. H. Hartridge, F.R.S.

### Beet Sugar Effluent

Speaking on May 4th before the London section of the Society of Chemical Industry, Mr. A. Parker, D.Sc., described the work of the Water Pollution Research

Board in the provision of cleaner rivers. The work of the Board, he said, had definitely shown that millions of gallons of water used by a beet sugar factory which were previously wasted can be saved and re-used after treatment by a simple and practical process, while, if it is necessary to discharge the water into a stream, it can be purified and pollution avoided by percolating filters. This was important, for the waste water from a single factory may be equivalent in its polluting character to crude domestic sewage from a town with a population of about 300,000 people. If the waste waters from all the beet sugar factories in this country were discharged into streams they would cause as much pollution as the sewage from a population of four or five million people.

### Fellowship of Medicine and Post-Graduate Medical Association

The following all-day courses will take place during May: thoracic surgery at the Brompton Hospital (May 11th to 16th); urology at St. Peter's Hospital (May 18th to 30th, men only); proctology at the Gordon Hospital (May 25th to 30th); an afternoon course in venereal disease will also be held at the London Lock Hospital (May 25th to June 20th); and a week-end course in general surgery at the Cancer Hospital (May 16th and 17th). Courses are open only to members and associates of the Fellowship, and further information may be had from the secretary of the Fellowship, 1, Wimpole-street, London, W.1.

ADDRESSES AND ORIGINAL ARTICLES

CARCINOMA OF THE STOMACH\*

By Sir James Walton, K.C.V.O., M.S., B.Sc. Lond.,  
F.R.C.S. Eng.

SURGEON TO THE LONDON HOSPITAL

IN giving this oration I have thought it best to limit my remarks to the results of my own experience, which at least has the merit that it is based upon thirty-five years' work. Not all would accept the wisdom of such a method, but would rather agree with the preacher who in the Book of Ecclesiastes says: "I looked on all the works that my hands had wrought and on the labour I had laboured to do and behold all was vanity and vexation of spirit, and there was no profit under the sun." For my own part I prefer to follow the lead of one who, considered a pagan, is responsible for some of the finest Christian teaching, one of whom the Emperor Antonius stated that "he thanked the gods that he could collect from his writings the wherewithal to conduct life with honour to himself and advantage to his country." I refer to Epictetus who in his Enchiridion pointed out that "every art is wearisome in the learning of it,—yet things that are made by the arts immediately declare their uses and in most of them there is something which is attractive and pleasing." In my own work I have been fortunate enough in finding much that has been attractive and pleasing.

It has been wisely said that "to travel hopefully is better than to arrive and the greatest happiness is in labour," and the older members of this society will I know join me in saying that the only constant and certain happiness in life, the only happiness that lies in a man's own hands and which is not destroyed by untoward circumstances beyond his control, lies in his labour. I am venturesome enough to hope that, although I can produce nothing new, the work which has given me so much pleasure may be of some interest to others.

Of the many branches of abdominal surgery I have felt that a consideration of carcinoma of the stomach would be the most appropriate, for this disease is one upon which the attention of the whole medical world is centred, and it has only been by the slow aggregation of small details in diagnosis and treatment that we are able to say to-day that although the outlook is still bad it is no longer hopeless, as was supposed a few years ago.

Frequency

Carcinoma of the stomach is undoubtedly a common disease and forms a high proportion of all gastric lesions; but I am doubtful if its frequency is increasing. The number of cases of carcinoma, of all peptic ulcers, and of ulcers of the body of the stomach that have occurred in my own practice yearly from 1913-35 are shown in Fig. 1, and it is noticeable that there has been no appreciable rise in the number of carcinomata in the last seven years. The curves for carcinoma and for ulcers of the body run nearly parallel. To a lesser degree they are simulated by the curve for all ulcers. The annual variation in the numbers of peptic ulcers is probably due to changes in the method of treatment. The popularity of surgical treatment reached its peak in 1930, since

when the numbers have fallen; but it is a remarkable fact that the curve for carcinoma shows a similar rise and fall. Does this mean that more cases of carcinoma are overlooked to-day and are treated as ulcers, or are more ulcers cured medically and so do not progress to carcinoma?

Another important fact that is made evident is that of all gastric operations between one in three and one in five is performed for carcinoma.

Age and Sex

Generally speaking carcinoma is a disease of middle age, the greater number appearing between the ages of fifty and sixty. In aged people it becomes, like carcinoma elsewhere, relatively rare. The late Sir Jonathan Hutchinson used to say that elderly people were beyond the carcinoma age, but it must be remembered that very aged people form but a small proportion of the total population, and before such a belief can be held it would be necessary to know what proportion the cases of carcinoma formed of the total numbers of that age. The age-frequency in my own series is shown in Fig. 2, where it is compared with the curves of frequency of ulcers of the lesser curve and of all ulcers of the stomach. The apex occurs a decade later than that of ulcers either of the lesser curve or of all ulcers, which is reached between forty and fifty. Not only are the curves very similar but as many as 5 cases of carcinoma occurred before the age of thirty.

The sex-distribution is more equal than that of most peptic ulcers (Table I.). The total number of

TABLE I.—Sex-incidence

	Totals.	Males.	Females.	% Males.
Duodenal ulcers ..	1017	847	170	83.3
All ulcers .. ..	1888	1447	441	76.5
Lesser curve ulcers ..	646	483	163	74.5
Carcinoma .. ..	461	317	144	68.7
Hour-glass stomach ..	89	1	88	1.1

all chronic ulcers was 1888, of which 1447 were in males. But since duodenal and gastrojejunal ulcers never become carcinomatous it is of more importance to study the sex relationship only in the lesser-curve ulcers. These were 735 in number, of which 484 were males. It is however an interesting fact that the lesser-curve ulcers which are associated with an hour-glass constriction only occur in women and apparently never become carcinomatous. They seem to be a class of lesion distinct from the ordinary peptic ulcer. There were 89 such cases, and if they are eliminated there are remaining 483 males and 163 females. These figures I regard as important, for it is still often stated that ulcers of the body of the stomach are commoner in females than in males, whereas in my experience the reverse has always been true.

Among patients with duodenal ulcers the predominance of males is more marked, there being in my own series 1017, of whom 847 were males. In carcinoma, on the other hand, of 461 cases only 317 were males.

Pathological Varieties

Carcinoma of the stomach is usually primary, although it may occasionally be due to spread from some neighbouring viscus. When primary it may

\* The annual oration for 1936, delivered before the Medical Society of London on May 11th.

arise in a healthy stomach, or in one which is the seat of some previous lesion. The two common pre-existing lesions are adenomata and chronic peptic ulceration.

CARCINOMA SECONDARY TO ADENOMATA

Adenomata of the stomach are but rarely seen surgically. In my own series of over 2500 operations upon the stomach there have only been 6 cases. Even post-mortem statistics show that they are relatively rare lesions, Stewart finding only 56 examples in 12,800 autopsies. Like papillomata of the colon they are prone to become carcinomatous, 28 per cent. of Stewart's 56 cases showing this change. Of 322 of his cases of carcinomata 4.7 per cent. were associated with adenomata. McRoberts found that four out of five cases and Benedict seven out of seventeen cases treated surgically showed carcinomatous changes. The large papillomata which, situated near the pylorus, may initiate an intussusception are especially likely to be carcinomatous. A rare change is the condition known as polyadenomata or polyposis of the stomach which may consist of multiple discrete predunculated tumours, or form confluent masses showing as well demarcated plaques. Brun and Pearl were able to collect only 84 reported cases. This condition, regarded by many as the result of chronic gastritis, is also prone to become carcinomatous, four out of fourteen cases collected by Mills showing this change. In the condition which I have previously described as massive carcinoma of the greater curvature there is a probable but less clearly defined relation to adenomata. On clinical examination a mass is felt in the epigastrium which is so large that surgical intervention may be regarded as hopeless. At operation however the tumour which arises about the middle of the greater curvature is freely movable in spite of its size and of the fact that the gastrocolic omentum may be in part involved. Metastases are usually limited to the glands along the greater curve in the immediate vicinity of the growth and a

FIG. 1.—Annual incidence.

partial gastrectomy is usually possible. It is such cases that warn us never to refuse operative relief solely on account of the size of the tumour. They are relatively rare, there being only 11 examples in my series of 458 cases. The stomach shows a large fungating and often partly necrotic mass spreading into the stomach from the greater curve. In spite of its size the prognosis is relatively good. The rarity of this variety, its slow onset, the large mass with but few secondaries, the unusual site of origin and the tendency to necrosis and hæmorrhage and its relatively benign nature all suggest that it has arisen from an adenoma.

CARCINOMA SECONDARY TO PEPTIC ULCERATION

A relationship between chronic peptic ulceration and carcinoma has long been suspected, but an almost acrimonious discussion has arisen as to its frequency, the figures varying from 71 per cent. of carcinoma arising in ulcer as given by Wilson and McCarty to the complete absence of such a relationship as claimed by MacLean. To-day the figures of Stewart are generally accepted. He concluded that 9.5 per cent. of cases of chronic ulcer become carcinomatous and 17 per cent. of cases of carcinoma originate in a chronic ulcer. Clinical criteria are notoriously unreliable, although Hurst has produced evidence to show that the presence of a high acidity is suggestive that the carcinoma originated in an ulcer. In my own series I have only included those cases:—

1. Having a history of many years' standing in which the early symptoms were periodic;
2. Having a relatively high test-meal acidity;
3. Showing a condition at operation suggestive of a chronic ulcer; or
4. Showing pathological evidence of an old chronic ulcer.

Forty-four of the cases filled these requirements—that is, approximately 10 per cent—which is rather less than Stewart's figures, but it of course does not include the inoperable cases which were not investigated pathologically. It is important to appreciate this possibility, and if the symptoms are suggestive of such a change a partial gastrectomy should always be performed. There were 8 such cases in my own series,

FIG. 2.—Age-incidence.

carcinoma being discovered only after microscopic examination. The history of carcinoma in its early stages may also closely resemble that of chronic ulcer, so that an even higher percentage of the cases diagnosed clinically as chronic ulceration become malignant.

In a previous communication I discussed the frequency with which carcinoma arises after palliative operations for ulcer. The cases were found to fall into three groups. In the first a gastro-enterostomy is performed for an ulcer so large and so adherent that a radical operation is considered inadvisable. Symptoms of carcinoma soon follow, and it is almost certain that this lesion was present at the first operation. In the second group a gastro-enterostomy is performed for an ulcer at the pylorus or in the duodenum, and after a considerable period a carcinoma appears in the body of the stomach remote from the old ulcer. It is a new and distinct lesion. The third group consists of those cases in which the carcinoma is found in the area of the stomach in which the ulcer was situated, and although it may arise many years afterwards probably originates in the scar of the old ulcer. In my own series of 1888 operations for peptic ulcers there were 16 examples of subsequent carcinoma and 2 other cases where the first operation for peptic ulcer had been performed by another surgeon, making 18 in all for investigation (Table II.). Of these, four belong to the first group

TABLE II.—*Carcinoma in Scar of Healed Ulcer*

—	Cases.	Years.
I. Shortly after ..	4	—
II. Remote from ulcer ..	6	4, 7, 12, 15, 17, and 25
III. Later in scar ..	8	2, 4, 4, 5, 6, 6, 15, and 21

and six belong to the second group, occurring 4, 7, 12, 15, 17, and 25 years respectively after the primary lesion. Eight belong to the last group, and it is in these alone that it can be suggested that the carcinoma arose in the scar of the ulcer.

An interesting question is whether the acidity decreases with the onset of carcinoma. Dr. Hurst has always failed to find such a change. I had believed it probable, and this present series appears to support my views, for in 10 of them a test-meal had been done previous to the operation for ulceration and again when the patient was admitted with carcinoma. The test-meal before the first operation showed on the average a free HCl of 0.15 and a total acidity of 55. At the time of the second operation for carcinoma 8 showed a complete absence and 2 a reduction of free HCl. In all of these cases however a gastro-enterostomy had been performed, and the reduction might have been dependent upon this step rather than upon the carcinomatous change.

Carcinomata of this nature will present the pathological characters of an ulcer with a varying degree of visible carcinomatous change. In early cases the diagnosis of carcinoma may only be possible on microscopic examination, while in the later stages the mass of growth may be so extensive that it is impossible to determine with the naked eye whether the ulcer is primary or secondary. Microscopic examination will nevertheless often reveal characters of the original ulcer. As Newcomb points out, the most important of these are complete destruction of the muscle in the floor of the ulcer; a large area of dense fibrous and granulation tissue, also in the floor; the presence of endarteritis and thrombo-

phlebitis in the vessels around, and fusion or close approximation of the muscularis mucosæ and the muscle at the margin of, the ulcer.

#### PRIMARY CARCINOMATA

About 80 per cent. of all cases are usually regarded as primary—that is, as arising from no known cause and not being secondary to any antecedent lesion in the stomach. Hurst however has produced considerable evidence that this form of carcinoma is dependent upon chronic gastritis. He believes that the achlorhydria is caused by the gastritis and is not due to the growth. He found that in almost every case of undoubted ulcer-cancer free HCl was present, but when there was no evidence of a previous ulcer acid was usually absent even in the very early stages of the disease. He states that carcinoma never develops in a healthy stomach, but if a patient with a constitutional predisposition to carcinoma also has achlorhydria and gastritis he will probably develop carcinoma, and that the early recognition and treatment of the gastritis will diminish the frequency of carcinoma. His work is very suggestive but if true would indicate that ulcer is a more common cause of carcinoma than is usually believed. In my own series about 35 per cent. showed a high acidity, whereas only 10 per cent. fulfilled my criteria.

Many different types of growth are seen which are in the main dependent upon the amount of reactionary fibrosis, the following forms being usually recognised.

1. *Atrophic scirrhus, or leather-bottle stomach.*—This is a rare change, there being only 8 examples in my series. It is characterised by a dense fibrous thickening, occasionally limited to the pyloric portion, more commonly involving the whole wall of the viscus but being sharply limited at the pylorus. The stomach is shrunken and the wall thickened and rigid. The fibrosis is so extensive that it has often been regarded as inflammatory or syphilitic, and the condition described as *linitis plastica*. In my own cases the mucosa has never been ulcerated. The neighbouring glands may be enlarged and hard, but those remote are rarely affected, and as a rule there is no evidence of secondary deposits in other viscera. Microscopic examination reveals extreme fibrosis, but the London Hospital cases have all contained carcinoma cells although often widely scattered. This variety appears to correspond with atrophic scirrhus of the breast.

2. *Scirrhus carcinoma.*—The fibrosis with this variety is less extensive. Most commonly found at the pylorus it generally forms a hard irregular thickening of the wall with stenosis of the canal. The peritoneal surface is nodular and thickened with infiltrated lymphatics often running over its surface to the neighbouring glands. On section the wall is much infiltrated, the mucosa usually showing a flattened area of ulceration with raised nodular edges. Although the primary growth may be small, secondary deposits are common in the glands and metastases may be widespread in other viscera.

3. *Medullary carcinoma.*—In this variety the amount of fibrosis is relatively slight. The affected portion of the stomach is much thickened, forming a firm solid tumour with a nodular irregular peritoneal surface, from which infiltrated lymphatics may run to the considerably enlarged glands. On section the walls are widely infiltrated with growth which also forms a large mass projecting into the stomach. It may be nodular with small necrotic areas or deeply ulcerated, in which case the edges

of the ulcer are raised, irregular, and necrotic. This variety is most common on the lesser curve but may be seen at the cardia and pylorus.

4. *Diffuse carcinoma*.—Very rarely there may be a widespread infiltration of the mucosa of the stomach with nodular masses of growth which are especially marked in the apices of the rugæ. The substance of the stomach wall may show slight infiltration, but the dense thickening seen in the leather-bottle stomach is absent. There are usually widespread secondaries, especially in the bones, and the condition may be associated with a profound myelopathic anaemia.

These varying forms appear to be dependent upon the amount of reactionary and protective fibrosis, but the appearance is of no prognostic value. A small pyloric scirrhus may be seen with extensive metastases or recurrence may take place shortly after removal. On the other hand a medullary growth may be so extensive that excision is performed more as a palliative measure but the patient remains free for many years.

A rare form occurring in about 5 per cent. of the total is colloid carcinoma in which the growth is made up of semitranslucent globules of colloid material. Although usually spoken of as a colloid degeneration the cells are highly malignant and there is often widespread infiltration of the walls and extensive involvement of the lymph glands, the cells in all areas showing the characteristic colloid change.

5. *Squamous carcinoma*.—It is probable that this variety always commences in the lower end of the œsophagus. At times however it forms a soft villous and ulcerated mass which spreads down the lesser curve without obstructing the œsophagus, and thus appears to be gastric in origin. The true nature of the condition may then only be determinable on microscopic section.

#### SARCOMA OF THE STOMACH

Gastric sarcoma often gives a history identical with carcinoma, and its nature may remain uncertain until microscopic sections are examined. It is a rare lesion, there being only 3 examples in my series. Of the different forms the round-celled and sometimes the lymphosarcoma give the closest resemblance to carcinomata. These may form large sessile masses three or four inches in diameter which only spread a short distance into the stomach so that a firm flat plaque may be formed. It may be ulcerated in the centre but rarely to the same degree as a carcinoma. The substance of the growth is firm and white and widely invades the stomach wall, but in the lumen appears to be sharply limited. On the peritoneal surface small raised nodular masses of growth may be seen.

#### Methods of Spread

Carcinoma usually originates in the lesser curve or pylorus, and infiltrates the wall more widely than is apparent to the naked eye. The lesser curve is however relatively short, so that any form of partial gastrectomy has to be more limited than would be considered wise with carcinoma elsewhere, and for this reason the recurrence rate is high. Fortunately the duodenum shows nearly as remarkable an immunity to the spread of carcinoma as it does to the presence of a primary growth, and hence section of the duodenum is usually simple. Occasionally small nodules of growth may be seen in the first half inch of the duodenum, but it is nearly always possible to get beyond them.

The arrangement of the lymphatic fields and the path of the lymphatic flow are so well known that it is unnecessary to describe them. In practice the two areas of involvement which may make resection difficult or impossible are the retropyloric glands and those of the lesser curve. Sometimes one of the retropyloric glands is extensively involved and may be adherent to the neck of the pancreas; great care must then be taken in determining the extent of the disease, for it is an easy matter to divide the neck of the pancreas in the belief that an enlarged gland is being dissected from it. In the lesser curve glands the disease spreads up towards the œsophagus and then down to the glands around the cœliac axis, extensive metastases in the latter situation being a frequent cause of inoperability. Even if these glands appear to be unaffected they should always be removed, and in the last few years it has been my invariable custom to divide the coronary artery close to its origin from the cœliac axis and to remove all the glands that are around it, a step which I believe has done much to improve the ultimate prognosis.

Spread to the peritoneum, and through it to the pelvis and ovaries, must always be looked for. Multiple hard secondary deposits in the great omentum or in the parietal peritoneum may be found with relatively small and otherwise easily removable growths, and the same is true of the pelvis or ovaries where large masses of growth forming the so-called Krukenburg tumour may occasionally be seen.

The frequency of secondary deposits in the liver is uncertain and erratic. A huge mass of growth may be found in the stomach with the liver quite unaffected, while a small primary growth may be seen with the liver full of large secondary masses.

Direct spread to other viscera is generally seen only in the late stages, but the pancreas is commonly involved in those cases which have followed an ulcer which has become adherent to the pancreas.

#### Symptoms

Even with the improvements in diagnosis brought about by the use of radiography and test-meals, only a relatively small number of cases are diagnosed sufficiently early to allow a radical operation. It is true that a large number of patients first seek advice when the condition is already inoperable, but there are still many who are treated for a benign lesion until the disease is far advanced. It cannot be too strongly impressed upon the physician and patient alike that the onset of persistent dyspepsia in one over the age of forty must be regarded as due to carcinoma until the contrary can be proved.

When the growth gives rise to obstruction the symptoms of obstruction always mask those of the growth. If situated at the cardia the lesion is gener-

TABLE III.—*Clinical Types*

Cardiac obstruction ..	34	Insidious onset ..	174
Pyloric ..	181	After ulcer ...	44
Sudden onset ..	28		461

ally diagnosed correctly, for it is universally recognised that steadily increasing difficulty in swallowing is most commonly due to carcinoma. These cases however, in the present state of œsophageal surgery, are the ones which are the least amenable to treatment. Fortunately they only form a small proportion of the total. In my series there were only 34 (Table III.).

It is when situated at the pylorus that the presence of carcinoma is likely to be overlooked, for stenosis

in this position may be caused by a peptic ulcer or an extragastric lesion. The short and steadily progressive history is the factor of chief import, and time must never be wasted by treating such a case with stomach washes. This is now rarely done, for it is realised that the presence of obstruction is one of the chief indications for operation even with a benign lesion. The increase of pain after the ingestion of food and its relief after the large vomits suggest a peptic ulcer, whilst the fact that even an obstruction due to a peptic ulcer will abolish the periodicity and cause loss of appetite and wasting may erroneously suggest carcinoma. This variety is relatively common, there being in my series 181 cases with some pyloric obstruction.

The position and the frequent scirrhus nature of this type of growth makes it the most favourable for operation. Nevertheless many have been watched so long that a radical removal is impossible. The important points in the diagnosis are the short and progressive history; the constant discomfort, which may be associated with real pain from gastric peristalsis; the presence of characteristic obstructive vomiting; the early loss of appetite, with decreased acidity; the evidence of a dilated stomach shown either by the presence of splashing, of a palpably contracted stomach, or of visible peristalsis; and the demonstration of a hard irregular tumour in the region of the pylorus.

With such symptoms the diagnosis of a mechanical obstruction is certain and the presence of carcinoma most probable. Operation should be advocated without delay. Radiography may confirm the diagnosis, but if the obstruction is complete may fail to distinguish a carcinoma from a benign lesion.

It is in lesions of the body of the stomach that the diagnosis is often so uncertain. As Lord Moynihan pointed out these cases may be classified into three groups: those appearing with a sudden onset, those with a slow, insidious onset, and those following an ulcer. In the first group the patient may have had a slight degree of dyspepsia which has not necessitated his seeking advice, or he may indeed have been quite unaware of any gastric trouble. The onset may be with sudden severe pain, often dating back to a definite meal. From the time of the onset the pain remains constant and is usually severe so that advice is generally sought within a few weeks, but even then the condition may be inoperable. In others the first symptom may be a severe hæmorrhage or more rarely still a perforation. The danger lies in the fact that the severity of the pain or of the hæmorrhage suggests a chronic ulcer rather than a growth, and much valuable time may be lost in giving medical treatment. This variety is relatively rare, there being only 28 in my series.

The most common form, and indeed the typical variety, is that with a slow and insidious onset, 174 cases in my series falling into this group. In the early stages the patient may only complain of loss of energy with no gastric symptoms, although if questioned he will admit to a diminished appetite. The symptoms are a steadily progressive discomfort with fullness which rarely amounts to severe pain in the epigastrium. It is constant throughout the day, although often increased by food. There may be the eructation of foul gas or of small quantities of foul and bitter fluid, and at times true vomiting. As time progresses the patient becomes depressed and anæmic and there is loss of weight. There may be visible loss of blood either in the vomit or in the stools, but if this be absent occult blood is usually found. A tumour may or may not be palpable;

even in advanced cases it may not be felt if high up on the lesser curve and under the costal margin. The test-meal usually shows a complete absence of free HCl and a low total acidity. The X ray findings are usually characteristic, there being a well-marked filling defect, a large and irregular ulcer, or an area of loss of peristalsis. The whole course of the disease as a rule only extends over a few months but is steadily progressive, although cases are seen where the history seems to extend back for a year or more. It is in this group that advice is often sought too late, or if sought early so much time is spent in investigation that when the diagnosis is certain treatment is impossible.

In my own series 44 cases were accepted as being secondary to a chronic ulcer. The carcinomatous change is suggested by definite alterations in the symptoms. They become much more constant, the characteristic periodicity being lost so that the last attack appears to be much longer. The pain becomes more constant throughout the day, although it usually becomes less severe. The appetite begins to fail, and this although the test-meal may show a relatively high acidity such as is found with the ulcer. Vomiting may cease to give relief to the pain. It is true that similar changes may occur with other complications of a chronic ulcer, but they are always suggestive and are not only an indication for surgical interference but for the performance of a partial gastrectomy even if at operation the lesion appears to be benign.

#### Treatment

The only treatment which to-day appears to offer any hope is surgical, but in my own series a radical operation was possible in only 173 of the 461 cases. Of these, 6 were treated by complete gastrectomy, an operation which is as a rule possible only in the leather-bottle type of stomach; and this leaves 167 cases of partial gastrectomy—that is, 36 per cent. of the total. In spite of the fact that so many patients do not seek advice until the condition is inoperable I cannot help but feel that these figures could be improved. A full investigation of all patients developing dyspepsia after middle age should be carried out, and unless a growth can be definitely eliminated an operation should be considered. In advanced cases operation should not be lightly refused, for not only may a large tumour be capable of removal but the patient may have a good chance of remaining free from recurrence. It is my own practice only to refuse operation if there is definite evidence of secondary deposits. Even if the disease be inoperable it is often a great solace to the relatives to know that an

TABLE IV.—Operability Rate

Period.	Total.	Removable.	Percentage.
1913-19 ..	92	26	27.9
1920-27 ..	139	49	35.2
1928-35 ..	230	101	43.9

operation was undertaken and the patient given every chance of relief. In this respect it is very hopeful to find that in my own series the operability rate has steadily improved. In the years 1913-19 there were 92 cases, 26 of which were operable—that is, 27.9 per cent. In the period 1920-27 there were 139 cases with 49 removals—that is, 35.2 per cent.—and in the last period, 1928-35, 230 cases, of which 101, or 43.9 per cent., were removable (Table IV.).

At operation a rapid survey must be made to determine the extent of the primary growth and of the lymphatic involvement and the omentum, peritoneum, and liver must be examined for secondary deposits. If the growth is operable, as wide a partial gastrectomy as possible should be performed. The limited area is that of the lesser curve, so that the line of resection must lie close to the œsophagus, about seven-eighths of the total area of the stomach being removed. The lymphatic glands of both curvatures are included, but it is not necessary to remove the whole of the great omentum unless the peritoneum be relatively widely involved. Care must be taken, in removing the glands around the pylorus, to see that all are removed and to make sure that if adherent to the pancreas this latter structure is not endangered. The duodenum is divided about one inch beyond the pylorus and the distal end closed and invaginated. The stomach is turned over to the left, thus giving free access to its posterior surface.

A step which I regard as important and which I have carried out in all my later cases is the removal of the glands around the cœliac axis. The coronary artery is identified at its origin, the lymph glands are stripped up towards the stomach, and the artery divided at its origin from the cœliac axis. The commonest site of recurrence is in these glands and a wide removal of them gives the patient a better chance of subsequent cure. The method of anastomosis is of little import. I still have a preference for the original Polya method where the jejunum is brought up through the mesocolon and united to the stump of the stomach with the afferent loop at the lesser curve, but care must be taken to leave a sufficient loop so that there is no tension upon the junction. If however there be any indication the jejunum may be united with the afferent loop to the greater curve or it may be brought in front of the colon and united with the afferent loop either to the greater (Moynihan method) or to the lesser curve (Balfour method). At one time I was very hopeful that the implantation of radium around the cœliac axis and the head of the pancreas would lessen the danger of recurrence, and use was made of it in 18 cases in 1928-30. It was found that there was a considerably greater risk of a duodenal fistula. The total mortality was approximately the same (i.e., 28 per cent.). Three of the cases treated in 1930 are alive and well to-day; that represents a percentage no better than by operation alone.

**Results of Treatment**

When a large series of cases is investigated the results are very disappointing. This is in part due to the fact that the symptoms are so indefinite in the early stages that surgical advice is not sought until too late and in part to anatomical considerations. The growth soon spreads beyond the area that is removable, and even if limited the surgeon has to be content with excising an area of healthy tissue much less than would satisfy him in removing a carcinoma elsewhere. For these reasons only a small proportion of the cases operated upon can be subjected to resection, and even in such cases the recurrence rate is likely to be high. In order to improve the patient's chances the surgeon is tempted—and indeed it is his duty with so dread a disease—to carry out a resection wherever possible. The operation is therefore always extensive and severe, and often has to be performed upon patients who are weak and debilitated from prolonged pain, loss of appetite, vomiting, and loss of blood. To a certain

extent these risks can be decreased by a preliminary blood transfusion and careful preparation. But even when all precautions are taken the conscientious surgeon is bound to have a much higher mortality with a partial gastrectomy performed for a carcinoma than for a similar operation for a chronic ulcer. Because of these difficulties the results in the earlier series were so poor that many physicians did not consider operation justifiable, and there are even a few to-day who still hold this view. In the later series however the results have improved considerably, so that there is now a danger that too optimistic a view may be taken. I have personally issued a warning of this, and lately several carefully prepared and valuable lists of statistics of the end-results have been published. It is remarkable that the majority of these, although originating in widely separated areas of the world, show a close similarity (Table V.). The greater number have found that in

TABLE V.—Reported Cases

Author.	Operated cases.	Radical operations.	Mortality.	Alive.	Years.

Balfour.	..	45-50 %	10 %	..	20 % of all.		19 % if glands.			

only about 30 per cent. of the cases is resection possible and that the operation shows a mortality of approximately 30 per cent. Moreover only a few of the survivors were well 5-10 years after operation. An outstanding exception to these figures is the report of Balfour of the Mayo Clinic who found that 40-50 per cent. of a large series were operable and the mortality was only 10 per cent., about 20 per cent. of all cases remaining well and free from disease 5-10 years later.

Disappointing though most of these figures may be they prove beyond all doubt that a certain number of patients are cured by operation, and that therefore in the present state of our knowledge where there is no alternative treatment operation should be advised wherever possible. In my own series the most helpful and encouraging points have been that although the total resection rate has been only 36 per cent. there has been a steady improvement when the figures are considered in three seven-year periods (Table IV.) and that a definite proportion have lived sufficiently long for operation to be considered a cure. The mortality-rate of those patients subjected to resection is lamentably high and if anything tends to increase (Table VI.). I have however previously pointed out that as the surgeon's experience increases his mortality-rate tends to rise, for not only are a larger proportion of difficult cases and bad operative risks handed over to him but with an otherwise fatal disease he will attempt to save more and more patients as his dexterity increases. The operative mortality in this series was 28 per

cent., but it is of interest as showing the bad operative risks of these patients as a class, to appreciate that there were 86 patients in whom gastro-enterostomy was alone possible and among them the mortality was even higher, being 32.5 per cent. Of the 167 patients treated by resection 28 are alive and well to-day, but there were 2 others who were apparently

TABLE VI.—Operative Results

—	All operations.	Radical operations.	Deaths.	Relieved.	Alive and well to-day.	P.G.E.	Deaths.
All cases.	461	167 (36%)	48 (28%)	34	28	86	28 (32.5%)
Operated 5 years or more.	324	116 (35.8%)	31 (26.7%)	..	20	60	19 (31.6%)

cured, one dying of pneumonia four years after operation and one of nephritis two years after, both showing no evidence of carcinoma at the time of their death. There were also 4 cases in which the operation was well worth while, 2 showing no signs of recurrence until eight years, and 2 none until four years, after operation. On the other hand, of the patients alive and well to-day some have lived for too short a period to be considered as cured, those alive and well at varying time periods after operation being shown in Table VII. In order to overcome to some

TABLE VII.—Length of Survival of Cases Alive

Years.	Number of cases.	Years.	Number of cases.	Years.	Number of cases.

17	1	6	3	1	3
15	1	5	7	Total	28
14	1	4	1		
10	1	3	4		

measure the fallacy of these figures I have considered in a separate group the patients operated upon not later than 1930, and the results are shown in Tables VI. and VIII. A consideration of these tables seems

TABLE VIII.—Late Results

—	Total.	Relieved.	Alive and well.	% of operative recoveries.	% of resections.	% of all cases.

Operated 5 years or more.	324	..	20	23.5	17.2	6.1

to show that a cure may be looked for in 6 per cent. of all cases that come to operation, in about 16.5 per cent. of those in whom a resection is possible, and in about 23.5 per cent. of those who survive the resection.

These figures are poor, but at least they encourage us to work for better results and to advise operation wherever possible. If we have yet far to travel we may certainly travel hopefully.

HYPERTENSION PRODUCED WITH BENZEDRINE

ITS PSYCHOLOGICAL ACCOMPANIMENTS

By S. A. PEOPLES, M.D.\*

AND

E. GUTTMANN, M.D. Munich †

(From the Maudsley Hospital, London)

THE fluctuations of blood pressure which accompany normal mental phenomena have been much investigated. A close connexion between blood pressure and emotions has been demonstrated here, which might be expected also to be found in the case of morbid states, especially the affective type. By the study of such physical relationship in mental illness one might hope to arrive at objective symptoms of such "functional" disorders, which are otherwise diagnosed mainly on the basis of subjective psychological phenomena. Furthermore, the reciprocal relation between emotions and their bodily concomitants suggests the possibility of a therapeutic approach from the physical side.

Pathological changes of the blood pressure are in the province of the physician rather than of the psychiatrist. The clear distinction between hypertension, as a disease sui generis, and arterio-sclerosis (of which an increased blood pressure may be a symptom) has stimulated interest in the pathology of blood pressure, and has attracted the attention not only of neurologists but of psychiatrists as well. E. Krapf has recently published a monograph on the mental disorders that occur in patients with arterial hypertension. The analysis of a large clinical material leads him to conclude that the lability of the blood pressure or its actual fluctuations play a far more important rôle in the pathogenesis of psychoses than one had previously supposed. He points out that some syndromes of different aetiology are similar or even identical, and he thinks that this may be due to the fact that fluctuations of the blood pressure are a link in the causation or perhaps supply a final

common pathway. His interesting theory seemed to offer a useful basis for experiment.

THE PRESENT OBSERVATIONS

These experiments were designed to answer the following question: What mental changes will take place in normal or mentally abnormal persons when their blood pressure is artificially altered?

Psychological experiments in man, especially with drugs, are always difficult to interpret, since so many individual factors must be considered; a discussion of these problems is to be found in a paper by Guttman and Maclay, who were faced with the same difficulty in experiments with mescaline. We are therefore giving here only preliminary report on some effects of Benzedrine, leaving their interpretation to a later publication in which our blood-pressure studies, including these experiments, will be more fully reported. Benzedrine is  $\beta$ -phenyl-iso-propylamine, which is similar in chemical structure to ephedrine and adrenaline. It was synthesised by Gordon Alles who with his collaborators first described its physiological action. All that is known of its action in man may be found summarised in a paper by Prinzmetal and Bloomberg on the Use of Benzedrine for the Treatment of Narcolepsy.

We made our experiments on 25 persons, all of them having two or more different doses. The drug was given orally in doses between 10 and 80 mg., in the form of 10 mg. tablets. In each subject the normal daily fluctuation of blood pressure was recorded, and the mental state was carefully considered. Each of the blood-pressure readings, mentioned below, was the lowest of a series of four readings taken at 5-minute intervals.

Among this group of 25 persons there were only 2 who did not show any reaction to the doses used. The lowest dose to which anyone reacted appreciably was 20 mg.; 22 of the patients reacted to 30 mg.

As benzedrine apparently is an adrenergic drug, its effect on the vegetative nervous system was of particular interest. On certain parts of the vegetative nervous system this was unexpectedly slight: there was no blushing or pallor and no alteration of the size of pupil, gastro-intestinal motility, perspiration, or genito-urinary function. In 7 cases series of blood-sugar readings were made during the experiment; there was no fluctuation beyond the normal limits. Respiration was unaffected. In some cases the appetite was less during the action of the drug, and about a quarter of the subjects reported dryness of the mouth.

The alterations in blood pressure were used as an index of the course and intensity of the intoxication. The latent period after the oral administration of the drug generally lay between 45 minutes and two hours. Once the action on the blood pressure had become apparent, the maximum point was reached in about an hour. The decrease was gradual; the normal pressure was reached between two and five hours after the peak, according to the dose given. In some cases, owing to external circumstances, the end-effects could not be recorded. The blood pressure always became normal within 24 hours after the administration of the drug. The intensity of the reaction apparently depends on several factors, the most important of which was the amount of the drug administered.

Thus in a typical case:—

Mr. B.—Normal pressure .. .. .	126/75
After 20 mg. .. .. .	138/88
" 40 " .. .. .	148/88

Another important factor is the constitution of the subject. As far as our general impression goes, persons with low and labile pressure reacted more than those with higher and more stable pressures. The pressure changes were chiefly systolic, the diastolic showing little or no increase, so that there was an increase of the pulse pressure. A typical reaction was, e.g. :—

Mr. C.—Initial pressure .. .. .	100/74
Maximum " .. .. .	142/84

In most cases the change of blood pressure was accompanied by an increase of the pulse-rate which was, however, not strictly proportional, as shown in the following examples:—

	Initial value.	Maximum value.
Miss N. .. B.P. 114/76. Pulse 72	B.P. 134/82. Pulse 84	
Mr. L. .. " 116/68. " 84	" 144/78. " 120	

The acceleration of the pulse usually lasted longer than the increase of the blood pressure.

As regards sleep, Alles and Prinzmetal have already observed that benzedrine will awaken experimental animals from anaesthesia and produce insomnia in man. Therefore Prinzmetal and Bloomberg introduced it into the therapy of narcolepsy. We confirmed their observation with regard to insomnia. The majority of our subjects complained of a disturbance of sleep on the night after the experiment. They found difficulty in going to sleep and woke much earlier than usual. It is interesting to note, with regard to the mode of action of the drug, that there is sometimes a discrepancy between the effect on pressure and on sleep. Three cases with marked rise of blood pressure had no insomnia, and three others slept badly and had marked psychic symptoms, although they had little or no rise of blood pressure.

EFFECTS ON THE MIND

Our results with the drug in the mental field were unexpected, considering that it so closely resembles

FIG. 1.—Tapping test. Normal control. Time-intervals between taps before and after 0.04 g. benzedrine.

adrenaline which produces anxiety. It is necessary, however, in this connexion to bear in mind that it also resembles ephedrine chemically, and Dr. Mapother has observed some diminution of depressive symptoms or some mild euphoria after the administration of ephedrine, given for asthma (personal communica-

tion). The systematic investigation of the psychic effect of vegetative drugs is only in its infancy (see Lindemann's valuable contribution).

The first psychic symptom which struck us was the talkativeness of our subjects. Almost everybody showed an increased tendency to talk, but the effect was most striking in depressive patients; they overcame their retardation, and several of them talked spontaneously to other people for the first time since their admission. This improvement was also visible in the patients' movements. Some of the normal subjects showed a motor restlessness. The most interesting feature was a change of mood, experienced

common type of reaction. As regards individual differences it may be mentioned in this paper only that some persons exhibited changes of mood of the kind described, although they were reluctant to admit them. The converse of this was seen in a girl—depersonalisation and anxiety state—who was the only person whose reaction reminded one of an adrenaline effect; she felt giddy, cold, shivering, and weak, yet in spite of that she felt a mild elation and noticed that she was less concerned about her worries.

To demonstrate some features of the complex mental changes we used a few simple tests—e.g., we gave the patients Kraepelin's continuous addition test before and during the intoxication and in some cases we made control experiments at various times. Sixteen cases were tested in this way; nine of them showed an increase in the number of additions far beyond the probable error and the normal increase by practice. The rest had only slight increases or none.

Also in simple tests for estimating time some changes were demonstrable. The subjects were asked to repeat several times a time-interval, tapped out from them once, and their tapping was recorded on a kymograph. Where changes occurred they always pointed in the same direction: under the effect of the drug the intervals tapped became relatively shorter compared with the tapping under normal condition, either before or a day after the administration of the drug. (If one arranges the times of the single intervals in a curve, as in Figs. 1 and 2, the drug-curve is always turned clockwise away from the normal curve.)

#### CONCLUSION

This drug is certainly effective and a promising therapeutic ally, but one cannot make use of it until it is known whether permanent administration produces anything like adaptation, habituation, or even addiction. It also will have to be observed whether and how far the disturbance of sleep and appetite interfere with the therapeutic effect. The lines of further inquiry have been the change of tolerance, the reactions of depressions of different kind to the medication, and the effect of the drug on other psychopathological phenomena. These will be the subject of a further publication.

We wish to acknowledge our gratitude to Dr. E. Mapother for his kind permission to use the clinical material of the Maudsley Hospital and to Dr. F. Golla for putting at our disposal the facilities of the Central Pathological Laboratory. We also wish to thank Dr. G. Alles for the generous supply of the drug and for his many useful suggestions.

QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY.—The Duke of York presided over the annual court of governors of this hospital on April 29th. Over £16,000 towards the £30,000 needed for the first stage of the development programme has now been received and work on a new out-patient department is to begin immediately.

FIG. 2.—Results of same test in a depressed patient. Before and after 0.03 g. benzedrine.

in nearly every case. In no instance was anxiety produced or a depression deepened. The change was generally in the direction of euphoria. We shall give some examples of the subjective experience without attempting a detailed analysis of the underlying psychopathology.

One of our normal subjects said that she felt extremely elated, that she had no worries. She felt that the lectures she listened to were extremely lucid and interesting. She also reported an unusual self-confidence. She felt physically equal to any task. Another subject, a mildly depressed patient, stated that she felt full of energy and confidence, that she could think clearly and had no worries. She called herself "an exulted being." Another patient (depression with mild paranoid features) at first said he felt as if he were drunk. As this passed off, everything seemed brighter and more interesting. He felt relaxed and not restless as he was at other times. He ceased to have difficulty in concentration, so that he was now able to read a newspaper again; his worries had gone for the time being, he felt quite happy, realising that his previous paranoid ideas were unfounded.

These few examples may suffice to illustrate the

## PUERPERAL SURGICAL SCARLET FEVER

By A. H. G. BURTON, M.D., M.R.C.P. Lond.,  
D.P.H., D.P.M.

MEDICAL OFFICER OF HEALTH, ILFORD, AND MEDICAL SUPER-  
INTENDENT OF ILFORD ISOLATION HOSPITAL AND  
SANATORIUM; AND

J. H. WEIR, M.D., B.Hy. Durh., D.P.H.

ASSISTANT M.O.H., ILFORD, AND RESIDENT MEDICAL OFFICER TO  
THE ISOLATION HOSPITAL AND SANATORIUM

DESPITE the universal recognition of scarlet fever occurring in the puerperium, no clear conception of its pathogenesis or of its relation to ordinary scarlatina has yet been enunciated. THE LANCET, in a leading article in 1922, stated that the relation between puerperal sepsis and scarlet fever in the puerperium was not fully cleared up, although much attention had been given to it. The article criticised the contention that when puerperal sepsis and scarlet fever were concurrent they were in fact distinct and separate infections.

The earliest recorded observations on the subject appear to be those of Hamilton (1470), Welsh (1635), and Ludwig (1758), all of whom described conditions which were probably puerperal scarlet fever. After that there is nothing of note until classical accounts of the disease were given by Malfatti (1799) and Senn (1826) with whose observations most clinicians of the nineteenth century were in agreement and from whose findings two schools of thought emanated. The one held that the condition was a coincidental and concurrent simple scarlet fever complicating the puerperium, while the other maintained that the malady was a scarlatiniform erythema and merely a symptom of puerperal infection. These ideas found acceptance by many observers in the present century; for instance, Byers<sup>1</sup> notes that two types of scarlatiniform rashes may be encountered—mild and severe—but maintains that *true* scarlatina is rarely seen during the puerperium. In his opinion so-called puerperal scarlatina is practically always a form of septic infection with a rash only resembling the eruption seen in true scarlatina. Other writers, Thorp,<sup>2</sup> Cozzolino,<sup>3</sup> and Robinson,<sup>4</sup> on the contrary, record cases of definite scarlatina in the puerperium which were followed by simple scarlatina in other members of the same households, many being in newly born infants.

Delorme<sup>5</sup> holds a similar opinion in regard to the two varieties of puerperal scarlatina, and in support of his views cites certain peculiar features such as the absence of sore-throat, associated with little or no uterine infection in certain cases. De Lavergne and Fruhinsholz<sup>6</sup> conclude that there may be a specific puerperal scarlet fever different from the true scarlet fever that may also complicate the puerperium. They point out that certain cases of puerperal scarlet fever appear to have their path of infection by way of the genital tract and that these are notable for the absence of the typical buccopharyngeal picture of scarlet fever, in which it is admitted that the principal mode of infection is by droplets. Devraigne<sup>7</sup> agrees with their opinions and offers the so-called "phenomenon of Cantacuzène" as a possible hypothetical explanation. It is suggested that scarlatina is due to the combined action of a streptococcus in the cervix, an attendant supplying an ultravirus.

Baize and Mayer,<sup>8</sup> basing their observations on six cases in the Maternity Hospital at Lariboisière, find that the disease tends particularly to affect primiparæ,

especially on the third to fifth day after delivery. In most cases, they state, the source of infection cannot be discovered and the symptoms differ but slightly from those of ordinary scarlet fever. Most of their cases were also associated with signs of puerperal sepsis. The patients were transferred to the Hôpital Claude Bernard and the death-rate is not recorded.

Probably the most authoritative study on the subject in recent years is that of Lemierre and Bernard,<sup>9</sup> who base their conclusions on a critical examination and survey of 23 cases treated in the Hôpital Claude Bernard. They note: (1) the rarity of scarlet fever in pregnancy and after abortion, as opposed to its relative frequency in the puerperium, whether after a normal or an instrumental delivery; (2) the incubation period, 2-5 days after confinement, and therefore comparable to ordinary scarlet fever; (3) the abrupt onset characterised by pyrexia, malaise, vomiting, sore-throat, and headache, atypical cases presenting symptoms no more diverse than the varieties commonly encountered in ordinary scarlet fever; (4) the physical signs—eruption, "streptococcal tongue," facies, throat lesion—followed by a convalescence pursuing the same course and marked by the same complications as typical scarlet fever; (5) a positive Schultz-Charlton reaction whenever it was possible to perform the test in the early stages of the rash; (6) the similar results given by laboratory investigation of the bacteriology, hæmatology, and biochemistry of the two conditions, hæmolytic streptococci being found in the local lesions or in septic complications; and (7) a death-rate of approximately 15 per cent. They conclude that non-*puerperal* scarlatina and *puerperal* scarlatina are identical.

Of the 23 cases, however, there were only 14 in which the illness began within the normal incubation period of scarlet fever; the onset of some was as late as the nineteenth or twenty-third day and they cannot therefore be regarded as ordinary cases of "puerperal" scarlet fever, even if they were preceded by signs of puerperal sepsis.

It is clear that puerperal scarlet fever may be due to a specific infection either immediately before the confinement, or at the time of the confinement, or during the puerperium. The death-rate of scarlet fever following puerperal sepsis must not be therefore compared with the death-rate of scarlet fever arising from a specific infection at the confinement. Of the 12 patients in this latter group 3 died, 3 gave a positive blood culture for hæmolytic streptococci (of these 2 died), and several showed signs of puerperal sepsis; one infant died of septicæmia, another of erysipelas, and a third was born dead. Considering therefore only these 12 patients, the maternal mortality was 25 per cent. and the infantile mortality the same—a sufficient indication of the gravity of puerperal scarlet fever.

Warembourg and Demarez<sup>10</sup> give the following characteristics of puerperal scarlet fever: (1) it occurs in epidemics coincident with those of puerperal sepsis; (2) it is exceptional in pregnancy or after an abortion, but most frequent in the puerperium 2-5 days after the confinement; (3) there are rarely signs of infection in the genital organs; (4) it leads to death in a large proportion of cases. They consider that the infective organisms usually enter through the genital organs and only rarely through the nasopharynx.

The close connexion between scarlet fever and puerperal fever is shown by certain cases in a private nursing-home in Ilford.

On Oct. 8th, 1935, a patient with puerperal fever was removed to the London Hospital, where hæmolytic streptococci were found in her cervix. A throat swab was not taken.

On Oct. 14th a second case of puerperal fever was notified which was removed to the isolation block at Queen Charlotte's Hospital, where she died of general peritonitis. Hæmolytic streptococci were not found in a swab from the throat of the patient, but some of the same type as in the first case were cultured from her cervix. It was stated that the hæmolytic streptococci were not of the ordinary scarlatinal type but fell within an unusual group not generally accepted as causing scarlet fever, although the patient had a well-marked rash, peeling of the skin, &c., before she died.

On Oct. 18th the child of the keeper of the nursing-home was notified as suffering from scarlet fever.

The mode of infection in puerperal scarlet fever has been little studied. Okell<sup>11</sup> concludes that there are two conditions coming under this title—an ordinary scarlet fever due to primary faucial infection, and a primary infection of the uterus itself by a streptococcus of high toxigenic power. This would explain the varying death-rates given by various observers.

We would suggest that the second class of cases mentioned by Okell should be regarded as essentially a surgical scarlet fever with the local lesion in the genital tract, taking the form of either a streptococcal endometritis or, more probably, a streptococcal cervicitis. From this focus of infection streptococcal toxins are liberated into the general circulation and produce the characteristic picture of scarlatina, just as in ordinary scarlet fever they are evolved from the local throat lesion, or in common surgical scarlet fever from an infected wound. It may also be recalled that the injection of Dick toxin in active immunisation occasionally produces a "miniature scarlet fever," shown by malaise, sore-throat, vomiting, and a generalised rash. Locally the streptococcus produces the usual effects of puerperal sepsis.

The following is a typical case of surgical scarlet fever admitted to the Ilford Isolation Hospital on Oct. 31st, 1935.

Male, aged 4. Septic focus over tubercle of left tibia, followed three days later by sore-throat and malaise; next day he had headache and he vomited several times; two days later he developed a typical scarlatinal rash. Admitted to hospital on second day of rash. Examination showed intense generalised scarlatinal rash, the throat injected, oedematous, and exudate on the right tonsil. Faint circumoral pallor present. Septic focus on left leg at site mentioned, with free purulent discharge. Treatment: Scarlatinal antitoxin 18 c.cm. intramuscularly. Bacteriology: Throat swab; no streptococci present in cultures. Swab from septic focus on leg; hæmolytic streptococcus present in cultures, inagglutinable with type sera. Progress: Uninterrupted recovery; Dick test positive on eleventh day after serum; passively immunised with 5.0 c.cm. of scarlatinal antitoxin. Discharged Nov. 30th.

#### AN ACCOUNT OF THREE CASES

Three patients with puerperal pyrexia, all of which proved to have scarlet fever, were admitted to the Ilford Isolation Hospital in the autumn of 1935. The following is a summary of them.

**CASE 1.**—Aged 29; 3-para. Normal delivery of full-time child Sept. 24th, 1935. Small perineal tear repaired with one suture. Normal puerperium until Sept. 26th, when she complained of general malaise, headache, and dry throat. Slight rigor, Sept. 27th, followed by the appearance of a generalised scarlatinal rash.

*On admission* on Sept. 28th her general condition was good. There was a generalised scarlatinal eruption, injection of fauces; tongue thickly coated, becoming

subsequently typically "strawberry." The uterus was rather bulky; no tenderness or swelling indicative of local inflammatory condition; lochia normal and not offensive. One perineal suture in situ showing superficial sepsis. Diagnosis: Puerperal scarlatina.

*Bacteriological findings:* Throat swab: *Streptococcus viridans*, no evidence of *S. hæmolyticus*. Swab from cervix showed *S. hæmolyticus*, inagglutinable with the usual scarlet fever type sera. Treatment: Sept. 28th, scarlatinal antitoxin 20 c.cm. and 30 c.cm. intramuscularly. Sept. 29th, scarlatinal antitoxin 30 c.cm. intramuscularly. Progress: After a preliminary fall in temperature on Sept. 28th and an evening rise on the 29th, the temperature finally fell to normal 12 hours after the third dose of intramuscular serum. Since then recovery was uneventful and no further treatment was necessary beyond the removal of the perineal suture and the insertion of antiseptic pessaries. She showed, however, a typical scarlet fever desquamation.

**CASE 2.**—Aged 28; 2-para. Normal delivery of full-term child on Oct. 8th, 1935, by the same doctor as in Case 1. Episiotomy performed and repaired by one perineal suture. Some difficulty in micturition was experienced for four days after confinement. On the 14th she complained of headache and generalised scarlatinal rash appeared.

*On admission* on the 14th her general condition was good. There was a generalised scarlatinal eruption, injection of fauces and bright punctate rash on palate; tongue furred, subsequently becoming typically "strawberry"; no abdominal abnormality. The uterus was midway between umbilicus and symphysis; lochia profuse but normal and inoffensive; one perineal suture in situ. *Diagnosis:* Puerperal scarlatina. *Bacteriology:* Cervical swab: hæmolytic streptococci on culture, inagglutinable with type sera. Throat swab: no evidence of hæmolytic streptococci on culture. Treatment: Oct. 14th: scarlatinal antitoxin 48 c.cm. intramuscularly. Progress: Eight hours after the administration of the serum the temperature fell to normal, and by the next day the rash had almost disappeared. The patient felt greatly improved and stated that she was well enough to get up. She continued to improve until Oct. 18th when some hypogastric pain and tenderness were manifested. On examination the uterus was found to be half-way between the umbilicus and the symphysis, the left broad ligament structures to be enlarged and tender, and the lochia profuse but otherwise apparently normal and inoffensive. Following hot douches and the local application of heat the condition resolved in about 14 days, leaving no trace of broad ligament thickening or uterine enlargement. The patient desquamated in a typical manner.

**CASE 3.**—Aged 30; primipara. Instrumental delivery of full-term living male child on Oct. 18th by the same doctor as Cases 1 and 2. Perineum torn; two sutures inserted. Rise of temperature on the 20th, accompanied by slight headache, sore-throat, and malaise. Appearance of scarlatinal rash on the 21st.

*On admission*, on the same day, there was a generalised scarlatinal rash (intensity ++++) most marked on abdomen; throat markedly injected but no oedema; exudate on right tonsil; tongue white "strawberry." Punctate rash on palate. The uterus was four fingers-breadth above the symphysis pubis; lochia not offensive; cervix oedematous and badly lacerated without any extensive tearing. *Diagnosis:* Puerperal scarlatina. Treatment: Three intramuscular injections of scarlatinal antitoxin were given: 48 c.cm. on Oct. 21st, 30 c.cm. on the 22nd, and 48 c.cm. on the 23rd. *Bacteriology:* On Oct. 21st and again on the 30th cultures from throat swabs showed no evidence of hæmolytic streptococci. A cervical swab taken on Oct. 21st showed hæmolytic streptococci on cultures, inagglutinable with type sera. Progress: The temperature fell on the third day after admission and remained normal until the ninth day when it rose to 100.8° F., thereafter remaining intermittent for the next nine days. During this time the patient had a very severe attack of serum rash which doubtless was the cause of the pyrexia. Since then the temperature remained afebrile. The uterine condition rapidly cleared up and, although the

lochia became purulent and a small rectovaginal fistula caused some trouble, the whole local lesion had cleared up by the end of the fourth week. The convalescence was otherwise uneventful although accompanied by a very extensive, coarse desquamation.

The salient point in this series is that while each patient developed the typical syndrome of scarlet fever—including a well-marked faucial lesion, strawberry tongue, and brilliant rash followed by widespread desquamation—no hæmolytic streptococci were cultured from faucial swabs, yet in each case hæmolytic streptococci were demonstrable in plate cultures of cervical swabs. The three cases mentioned occurred in the practice of one medical practitioner in whom repeated throat and nose swabbing failed to demonstrate the presence of hæmolytic streptococci. It appears therefore that in these cases the local lesion and probable point of entrance of infection was the uterine cervix. The general manifestations—rash, toxæmia, &c.—arose from the absorption of toxin from the cervix, as also did the oral and faucial lesion noticed in all cases. In other words, the evolution of physical signs was similar to the process involved in surgical scarlet fever or in the "scarlatinoid syndrome" which may occur during active immunisation with Dick toxin. It will be further noted that all the cases quoted ran the usual course of ordinary scarlet fever both in the acute and convalescent stage.

Treatment by serotherapy in each instance was attended by most gratifying results; certainly none suffered as a consequence, and no serious complications developed. Having regard to the severity of the acute stages encountered it appears that definite credit must be attached to the serum administration. It seems extremely problematical whether such a response would have followed treatment without the use of antitoxin. The absence of mortality is striking when contrasted with the figures quoted by Benthin<sup>12</sup>—viz., those of Gahet (8.7 per cent.), Schmidt (12 per cent.), Posch (16 per cent.), Olshausen (48 per cent.).

This view does not accord with that expressed by Benson and Rankin,<sup>13</sup> and Colebrook<sup>14</sup>; both agree that serum is of little avail in puerperal sepsis, and the latter maintains that in many instances it is actually harmful. On the other hand, Selwood Lindsay<sup>15</sup> found that definite benefit accrued when serum was given at an early stage in adequate doses; it is well to note this analogy.

For this reason we feel that the use of scarlatinal antitoxin should not be abandoned in the treatment of puerperal sepsis, that it is most emphatically indicated in puerperal scarlatina, and that many other non-eruptive cases of puerperal streptococcal infection may derive some benefit from its early administration.

#### SUMMARY AND CONCLUSIONS

(1) The three cases of puerperal scarlet fever described were all in the practice of one medical man. None showed hæmolytic streptococci in the throat, but all showed them in the cervix; the organisms were all inagglutinable with the ordinary scarlet fever type sera.

(2) The nose and throat of the doctor concerned and of those in attendance, who were different in each case, were negative for hæmolytic streptococci, indicating that the disease was not a droplet infection.

(3) It is suggested that these cases of puerperal scarlet fever, in which the organism is located in the cervix and not the throat, are properly described

as *puerperal surgical scarlet fever*, and the prognosis is probably quite different from those in which the organism is found in the throat.

(4) Puerperal fever without a rash, when due to a hæmolytic streptococcus, does not differ from puerperal surgical scarlet fever except in some cases, in the type of organisms, and in others, in the susceptibility of the patient.

(5) Definite benefit accrued in each case from the administration of scarlet fever antitoxin. Although they do not admit of definite proof, we believe that the results would not have been so favourable had the cases been treated by any means other than serotherapy.

(6) Despite recently adduced evidence to the contrary, we are of the opinion that all such cases—and many others of puerperal sepsis, even when no scarlatinal rash is manifested—would be benefited by the early administration of an adequate amount of scarlet fever antitoxin.

### THE TREATMENT OF VESICOVAGINAL FISTULA WITH SPECIAL REFERENCE TO IMPLANTATION OF THE URETERS

BY G. STEWART WOODMAN, M.B. Durh.,  
F.R.C.S. Edin.

LATE PROFESSOR OF CLINICAL SURGERY, BAGHDAD

THIS article consists of a summary of work carried out under conditions which for many reasons, chiefly the lack of a trained nursing staff, would nowhere be regarded as satisfactory. The series covers two periods as shown in the Table. (In 1922 and 1923 my duties were in a male hospital only.) A number of cases operated on during the three years 1925-27 have not been included as I have been unable, owing to administrative difficulties, to trace their records.

Year.	Cases.	Methods of treatment.			
		Suture.	Deaths.	Implanta- tion.	Deaths.
1921 and 1924	11	4 (6)	0	7 (12)	1
1928-33 ..	43	28 (30)	0	15 (25)	4
Total ..	54	32 (36)	—	22 (37)	5

The figures in parentheses indicate the actual number of operations.

*Causation.*—The patients were all Arabs (Muslim, Jew, or Christian), and only one of them was literate. The fistula was always the result of difficult labour,

often under tribal conditions and always in the absence of any medical aid. There were two exceptions: in the first a large calculus had perforated the vaginal and vesical walls, and the second followed the removal of the cervix uteri and the application of radium after a vaginal hysterectomy, both of which operations were performed in another country.

*Associated injuries.*—The commonest were perineal lacerations and all degrees of vaginal scarring—a "sump" between a posterior cicatrix and the cervix was noted in four cases. Two women had a recto-vaginal fistula as well, and in three a urethrovaginal fistula was also present. All gave a history of a stormy puerperium and the majority had phosphatic vaginal incrustations and vulval ulceration, often severe.

*Fistula.*—The duration of the longest fistula was two years, of the shortest six weeks. The opening was always partly in the midline, indicating its site of origin. Its size varied from that of a small date-stone to a gap admitting four fingers in which most of the vesical mucous membrane was either prolapsed or visible. With little or no vaginal scarring its long axis was parallel with that of the vagina; with gross scarring the opening was largely transverse. The ultimate shape appears to depend on the pull of the cicatricial tissue, and the size seems, at any rate in part, directly proportional to the period during which the presenting part remains impacted. In a patient who had been five days in labour the anterior lip of the cervix had also sloughed.

*Suture per vaginam.*—This operation was performed in 32 cases. It has been my experience that, so long as the internal vesical sphincter is not involved in the fistula, and even in the presence of the grossest vaginal cicatrices with retraction and fixation of the anterior and occasionally the posterior vaginal wall also, it is possible to close the opening by a relatively simple vaginal operation. In 1921, before appreciating this fact, attempts at vaginal repair failed in two cases because the sphincter involvement had not been noted. The chief essentials are generous excision of scar tissue, adequate but not excessive mobilisation, and careful paring of the vesical and vaginal edges of the fistula, combined with *accurate suture without tension*. Two rows of interrupted No. 0 Kalmerid catgut sutures are placed, one in the submucous and one in the muscle coat of the bladder. A third layer approximates the vaginal mucous membrane as far as possible at right angles to the line of the vesical layers. The vagina is lightly packed with gauze wrung out of equal parts of acriflavine and paraffin, and the bladder is drained by catheter (except when the patient pulls it out). Gauze and catheter are changed daily, and the latter is dispensed with after the seventh day.

In no case without sphincteric involvement has the vaginal operation failed. In two women a second operation was required to close a small leak at a lateral angle of a transverse fistula. In the presence of a transverse fistula with much scarring, suture of the angles of the wound, where a leak is most likely to occur, requires much care and thoroughness in a confined space. In these two cases the leak was due, I feel sure, to inadequate excision of scar tissue, although in both a great deal was removed. The maintenance of the patient in the best position for the surgeon is much aided by placing a large sandbag under the buttocks and by employing a modified Trendelenburg position with shoulder supports. Prof. Grey Turner tells me he finds the prone position with a pelvic support a great help, as it allows the

surgeon to view and work in the operation area from above instead of from below. I have no experience of suturing the bladder mucous membrane from a suprapubic wound as is, I understand, done by some. In straightforward cases it seems an unnecessary procedure which should be reserved for unusually difficult cases where at operation it is not found possible satisfactorily to close the fistula from below.

#### IMPLANTATION OF THE URETERS INTO THE RECTOSIGMOID

In this group there were 22 patients, in all of whom the fistula involved the internal vesical sphincter.

(A) *Stiles's operation* (18 cases).—I am much indebted to Prof. Grey Turner who in 1921 so kindly put me in touch with Stiles's original paper<sup>1</sup> written in respect of ectopia vesicæ, to the treatment of which he himself has made such notable contributions.<sup>2</sup> Except in one of the cases complicated by rectovaginal fistula, the ureters were implanted at intervals of 2-3 weeks through paramedian incisions. A remarkable feature has been the almost complete absence of adhesions, the presence of which might have been expected in patients with such histories—a tribute to the possibly insufficiently recognised powers of the peritoneum.

In the early operations the right ureter was first implanted because, owing to its greater distance from the bowel, it is the more difficult to implant in good alignment. In these the peritoneal incision to expose the ureter was made directly over it; later this incision was made parallel and just lateral to the right border of the bowel with curved upper and lower ends. By turning outwards the resulting peritoneal flap, the isolation of the ureter with its vessels intact and its implantation in good alignment was made easier. It was also found that a low implantation of the right ureter left ample room for the subsequent implantation of its fellow. In the sixth case after isolation and division of the right ureter, there was doubt of the adequacy of the blood-supply of its lower end,  $\frac{3}{4}$  in. of which was therefore excised and a higher implantation effected. In a later patient a similar condition was similarly treated. These experiences and the fact that the blood-vessels of the left ureter, owing to its greater proximity to the bowel, are in less danger, led me to continue to implant the right ureter first. Mayo's catgut guide has not been used. In one case only, where a firm adhesion necessitated a higher implantation of the left ureter than usual, have adhesions in any way impeded the second transplantation. A recent interesting note on technique by Everidge,<sup>3</sup> who refers to Nitch's work,<sup>4</sup> has afforded me the pleasure of reading the latter's views. He also advocates excision of any terminal portion of ureter of doubtful vitality and a higher implantation, as was done in my two patients. In a two-stage operation he recommends implantation of the left ureter first and gives reasons for this preference. His main one—a tendency of the pelvic colon to form an adherent sheet over the implanted right ureter—I have not encountered.

In the first of the two cases complicated by a recto-vaginal fistula (the second is reported below) an inguinal colostomy was prepared, and after implanting both ureters through a midline incision by Stiles's method at one sitting a large tube was sutured into the rectum in an endeavour to deflect the urine from the recto-vaginal fistula. The colostomy was opened after 24 hours. The tube was only partially successful and the recto-vaginal fistula was completely closed after two attempts. The artificial anus was then closed.

Here Coffey's catheters would have been of great value, but neither they nor sufficiently fine tubing were available. Despite their absence, it would I feel have been preferable after making a colostomy, first to close the rectovaginal fistula and drain the bladder by a tube of suitable size sutured into the vesicovaginal fistula to prevent leakage, and after a suitable interval to implant the ureters.

Of these 18 patients three died, one from peritonitis due to sloughing of the ureter following an attempt to close a ureteric fistula, the result of an unsuccessful implantation performed during my absence on leave, and one from pneumonia on the sixth post-operative day. In the latter there was no evidence of abdominal trouble but a post-mortem was not obtained. The third death took place on the tenth day and at post-mortem acute pyelonephritis was present in both kidneys.

(B) *Coffey's No. 2 (catheter) technique*<sup>5</sup> (1 case).—Both ureters were implanted at one operation, as Coffey recommends when catheters are used.<sup>6</sup> A block in the left catheter on the second day was cleared; ureterostomy for a further blockage on the fourth day did not save the patient.

(C) *Coffey's No. 3 (transfixion suture) technique*<sup>7</sup> (3 cases).—One patient died of shock 24 hours after operation, a result, I think, partly due to the use of spinal anaesthesia in a debilitated person. In the next patient the ureters were implanted at twenty days' interval, and the third refused a second operation after a successful implantation of her right ureter. The general condition of the patients operated on by this method was in marked contrast to that of those in which Stiles's technique was used. Restlessness, elevation of temperature, lumbar pain—frequently severe—and drowsiness were all noted before the establishment of the recto-ureteral fistula and their convalescence was more protracted.

Under the conditions referred to at the beginning of this paper the use of Coffey's catheter method was perhaps not justified. The few cases in which his transfixion suture was used do not permit of its comparison with Stiles's method, which, apart from my greater familiarity with it, I prefer on account of its greater simplicity and the appreciably shorter time it occupies.

#### DRAINAGE: ANÆSTHESIA

Drainage was only twice employed in the whole series—in the fatal case of ureteral fistula and once when at the second implantation the suture line was considered unsatisfactory and a piece of omentum was sown over it. The latter case did well. When Coffey's methods were used drainage was not employed as he recommends, though his is a very different type of case in which the possibility of infection seems to be much greater. The peritoneal incision made to isolate the ureter has always been closed. Great difficulty has been experienced in persuading the patient to remain in hospital for a period sufficient to cover both operations. Four women refused a second operation after the right ureter had been successfully implanted. It is difficult to convince an illiterate patient that she is really half cured; she notices only the persistence of the vaginal discharge of urine, not its diminution in volume, and her wish to be cured is overcome by the call of the desert and her desire to escape from the strange and, to her, uncongenial hospital atmosphere.

*Anæsthesia.*—Chloroform was used for the first 12 operations, intrathecal Tutocaine for 19, and intrathecal Percaine for 23. I prefer the latter which, in 20 c.cm. ampoules of a 1/1500 solution,

permits of accurate dosage. In the Royal Hospital, Baghdad, spinal anaesthesia has been employed for most abdominal operations for the past ten years, and I am satisfied that under local conditions it is the method of choice, both for vaginal suture and for implantation of the ureter.

#### RESULTS

Illiterate patients largely nomadic in habits and drawn from a vast area have made a follow-up practically impossible. Two patients have, however, been traced and each presents features of interest.

CASE 1.—Aged 15. Admitted to the Royal Hospital on May 12th, 1929, with a large vesicovaginal fistula admitting three fingers and involving the internal vesical sphincter, the result of difficult labour six weeks previously. The right ureter was implanted on May 15th and the left ureter on May 31st. After a straightforward recovery she left hospital on June 17th and was advised to report should she again become pregnant. She returned on May 9th, 1931, in labour with the fetal head arrested on the perineum. A healthy 6½ lb. boy was easily delivered with forceps. She stated that before the advent of pregnancy her bowels were opened 3-4 times daily and only rarely at night, and during pregnancy 5-6 times daily and generally once at night. Her general condition was good and the abdominal scars were sound. The old fistula admitted the tip of the index-finger into a contracted smooth-walled bladder. A radiographic estimate of renal function was postponed and she left hospital on May 19th after a normal puerperium. Later through the courtesy of the Brigadier commanding the Iraq Levies she was traced and brought down from the Kurdish mountains. Excretion urography with Uroselectan on Dec. 17th, 1931, showed a moderately large right-sided hydronephrosis with marked dilatation of the right ureter, but with no apparent abnormality in either the left kidney or ureter. She appeared to be in excellent health, and her only complaint was that she had been brought to hospital when she considered she was quite well. The right kidney was palpable but not tender. Sigmoidoscopy was refused and blood was not obtained for urea estimation. She again returned in January, 1935, pregnant for the third time (second post-implantation pregnancy), and came under the care of my colleague, Prof. D. A. D. Kennedy, at whose kind invitation I was present when on Jan. 13th he performed Cesarean section (the patient was in labour) and divided the Fallopian tubes. Inspection of the ureters showed the right ureter considerably dilated and three times as large as the left, which was much thickened and about twice its normal diameter. Her general appearance belied the previously known condition of her right kidney which was not noticeably more enlarged and not tender. On Feb. 4th uroselectan showed a slight increase in the dilatation of the right kidney. The left kidney was again reported normal. The old fistula showed no change. Sigmoidoscopy was again refused and after an uneventful recovery she left hospital on Feb. 5th.

CASE 2.—A 3-para, aged 24, was admitted on Sept. 3rd, 1929, with a vesicovaginal fistula involving the proximal urethra and admitting four fingers. The bladder was almost inverted, its mucous membrane in contact with a posterior vaginal wall covered in phosphatic deposit and much scarred. After treatment the right ureter was implanted on Sept. 21st and the left ureter on Nov. 27th. The persistence of a small amount of urinary discharge from the vagina led to its re-examination, which showed a small rectovaginal fistula about three inches above the torn perineum. No faecal matter escaped by that route, and as it was still unhealed on Jan. 12th an unsuccessful attempt was made to suture it. The patient left hospital to earn the family living as her husband was blind. She was next seen on June 17th, 1934, five years later, as an in-patient in a medical ward. She stated she had remained fairly well for four years; menstruation, previously regular, had ceased one year ago. Febrile attacks with shivering and left lumbar pain, occasionally severe, had been noticed, but recently these had ceased. For several

months there had been some faecal matter in the vaginal discharge. Her general condition was very poor; pulse-rate, 110; temperature, 99°-100° F. There was oedema of the feet but no ascites. Chronic bronchitis with much mucopurulent sputum was present. The rectovaginal fistula admitted the tip of the index-finger. Intravenous urography showed a faint definition of the calices of the right kidney and a complete absence of secretion on the left side. The blood-urea was 0.68 mg. per 100 c.c.m. After a blood transfusion of 150 c.c.m. the temperature rose to 105° F. but settled two days later, when a blood count showed: red cells, 1,400,000; hæmoglobin, 25 per cent.; colour-index, 0.89; leucocytes, 6900 (polymorphs 85 per cent., lymphocytes 12 per cent., mononuclears 2 per cent., eosinophils 1 per cent., basophils nil). The left kidney was removed on July 2nd under combined local and general anaesthesia. It was small and consisted largely of fibro-fatty tissue with no obvious cortex. The ureter was much thickened but only slightly if at all dilated. The patient stood the operation remarkably well, and her general condition on July 6th when I proceeded on leave was hopeful. Later she gradually went downhill and died on August 12th. Post mortem the right kidney was larger than normal. The capsule stripped easily, and a few small cysts were seen on the subcapsular surface, particularly over the lower pole. On section the whole organ was paler than normal, the cortex was diminished, and the cut surface presented multiple small cysts containing clear fluid. The calices showed a mild degree of hydronephrosis. There was no definite indication of inflammatory change and neither abscesses nor infarcts were present. The ureter showed a constriction about three inches above its implanted end. Above this site and below it as far as the implantation which merged insensibly into the bowel it was dilated to about thrice its normal diameter. A probe passed freely from the kidney pelvis to the bowel and in the reverse direction. Unfortunately portions were not removed for microscopy, and as the specimen was placed in Kaiserling's solution it has not been possible to study the microscopical appearances.

I am indebted to Dr. A. C. Norman, director of the X Ray Institute, Baghdad, for his assistance, and to the Director-General of Health in Iraq for permission to publish this article.

### THE SIGNIFICANCE IN CERTAIN CASES OF SYSTEMATISED INTERLOBULAR (PORTAL) INFILTRATION OF THE LIVER WITH LYMPHOCYTE-LIKE CELLS

By F. PARKES WEBER, M.D. Camb., F.R.C.P. Lond.  
SENIOR PHYSICIAN TO THE GERMAN HOSPITAL; AND  
A. SCHÜLTER, M.D. Münster i. W.  
HOUSE PHYSICIAN TO THE HOSPITAL

In cases where the clinical diagnosis (with or without the help of blood counts) has been some form of mycosis fungoides, Hodgkin's disease, lymphosarcomatosis or lymphadenosis, the post-mortem discovery (by microscopical examination) of a systematised interlobular infiltration of the liver with lymphocyte-like cells is generally accepted as signifying (or confirming) the leukæmic nature of the disease—i.e., that it was a kind of (generally aleukæmic) lymphadenosis.

One of us (F. P. W.) remembers as far back as 1894 a peculiar-looking man, aged 73, whose whole skin was infiltrated, notably the face, giving him a leonine appearance. The case had been regarded as one of mycosis fungoides, but no blood counts were made and the microscopical examination of the liver after death showed a systematised infiltration with lymphocyte-like cells. This almost conclusively pointed to a leukæmic nature of the disease; in other words, it proved that the case was one of (probably aleukæmic) lymphadenosis with predominant infiltration of the skin, as in the rare cases to which Kaposi long ago gave the name "lymphodermia perniciosa."

But nowadays we believe that in cases of aleukæmic lymphadenosis showing systematised interlobular (portal) infiltration of the liver at the post-mortem examination, the blood picture during life has demonstrated an absolute excess of lymphocytes in the differential counts of white cells. In this connexion the following recent case is of interest.

The patient, then aged 57, was first seen at the German Hospital in the latter half of 1934. He was losing weight and had enlargement of lymph glands in both groins, especially the left groin, and both axillæ; a slightly enlarged lymph gland was likewise felt under the lower jaw on the right side. An axillary gland excised in September, 1934, for "biopsy" purposes, was found to be diffusely infiltrated with lymphocyte-like cells; but on the whole, considering the absence of any characteristic change in the blood counts, the case was supposed to be most probably one of Hodgkin's disease (lymphogranulomatosis). The spleen could be felt. Otherwise no evidence of disease could be detected by ordinary examination and no mediastinal mass was seen in a radiogram of the thorax. The blood-serum gave negative Wassermann and Meinicke reactions. He was treated and kept under observation at the Radium Institute under Dr. Durden Smith, to whom we are also indebted for many blood counts. Small doses of Arsacetin by the mouth had been given in the German Hospital.

At first his general health remained good, but in September, 1935, he suffered from hæmaturia and pain in the left loin, and in October received radium treatment for a large mass (retroperitoneal?) in the upper left part of the abdomen. He lost ground, and in January, 1936, he looked pale and weak and had enlarged lymphatic glands on both sides of the neck, as well as in the axillæ and groins. A mass developed in the upper part of the mediastinum, for which he again received radium treatment. In January and February, 1936, he passed two little calculi in the urine. One of them was chemically analysed by Dr. M. M. O. Dannehl and found to be a pure uric acid calculus without inorganic constituents.

In February a slightly sanguineous serous effusion in the right pleura had to be tapped three times. He died on March 3rd, 1936. The patient had had practically no fever, but the pulse had been very frequent and the respiration somewhat increased during the last two weeks of his life.

*Necropsy.*—Generalised enlargement of the lymph glands: axillary, inguinal, cervical, para-aortic, mesenteric, and especially the mediastinal and hilus glands in the thorax. Erosion of the sternum by softened enlarged mediastinal glands. Liver (weight 800 grammes): chronic passive congestion; minute white nodules below the capsule and in its substance. Spleen (300 g.): enlarged and soft; no white nodules characteristic of Hodgkin's disease. The right kidney (enlarged, 225 g.) and the left kidney (160 g.) both contain calculi in pelvis and calices. The heart (353 g.) is of flabby consistence and anæmic. Emphysema and oedema of the lungs and bilateral hydrothorax. Retroperitoneal tumour-like mass in the neighbourhood of the left kidney. The bone-marrow from the shaft of the right femur is red.

*Microscopic examination.*—Diffuse infiltration of lymph glands with lymphocyte-like cells; outline of germ centres not entirely obliterated. The bone-marrow from the shaft of the femur shows much irregular infiltration with

similar cells. The retroperitoneal mass consists chiefly of similar cells; it encloses at one part a nerve ganglion. The liver shows a systematised infiltration of the interlobular spaces with lymphocyte-like cells, at parts forming small tumour-like areas. There is some infiltration of the pulp of the spleen. No definite infiltration is found in the sections of the kidney.

Prof. H. M. Turnbull, who examined the microscopical sections, has kindly furnished us with the following report:—

The infiltration consists of lymphocytes, and not of small cells of other kinds, for instance, medulloblasts. It is not a sarcoma of undifferentiated cells of the retroperitoneal tissues.

I can find no area with the characteristic reaction of Hodgkin's lymphogranuloma. Further, the Malpighian bodies in the spleen are not appreciably enlarged, but there is considerable lymphocytic infiltration of the pulp. The affection of the pulp rather than the Malpighian bodies definitely excludes Hodgkin's disease, even of the so-called sarcomatous type.

The differential diagnosis lies, therefore, between lymphosarcomatosis and lymphadenoid leukaemia. The nodular infiltration of the marrow favours lymphosarcomatosis rather than lymphadenoid leukaemia. On the other hand lymphosarcomatosis usually affects and enlarges the Malpighian bodies of the spleen and leaves the pulp intact. The infiltration of the pulp of the spleen is, however, not so great as in typical lymphadenoid leukaemia, in which the whole pattern, including the Malpighian bodies, is obliterated by lymphocytic infiltration. Further, although there appears to be an increase in the number of lymphocytes in the blood-vessels, this is insignificant in comparison with what is characteristic of lymphadenoid leukaemia; and lymphadenoid leukaemia may be found in the later stages of lymphosarcoma. I think, therefore, that this is an example of lymphosarcomatosis, of a type which is less closely allied to Hodgkin's disease than that in which the Malpighian bodies of the spleen are affected.

There is a myeloid transformation of the spleen, and a considerable number of normoblasts in the hepatic sinusoids. The myeloid transformation of the spleen is doubtless due to the lymphocytic infiltration of the bone-marrow.

The general distribution of the lymphocytic infiltration, in particular the involvement of the portal systems of the liver, points to a general hyperplasia of lymphadenoid tissue rather than an infiltration with secondary growth.

<sup>1</sup> The red cells had a fairly normal appearance, but on Jan. 2nd and Feb. 18th, 1936, anisocytosis was specially noted, and on the latter date one nucleated red cell (normoblast) was likewise seen.

<sup>2</sup> Counted at Radium Institute.

<sup>3</sup> At Radium Institute before treatment.

<sup>4</sup> At Radium Institute after treatment.

To this report we add a Table of the blood counts that were taken during the life of the patient. Some of them (especially that of May 15th, 1935), together with the systematised infiltration of the liver found by microscopical examination after the patient's death, seem to suggest that the lymphosarcomatosis was verging on a generalised condition of aleukæmic lymphadenosis.

We have to thank Dr. Durden Smith for his reports from the Radium Institute, and Prof. H. M. Turnbull for his histological summary.

### INTERMITTENT DIARRHŒA ASSOCIATED WITH BACILLUS ASIATICUS

BY GERALD SLOT, M.D., M.R.C.P. Lond., D.P.H.

SENIOR PHYSICIAN TO THE ROYAL WATERLOO HOSPITAL, LONDON; CONSULTING PHYSICIAN, LONDON COUNTY COUNCIL; AND

DOUGLAS BLOMFIELD, M.B. Lond.

HOUSE PHYSICIAN AT THE HOSPITAL

Two cases coming under this heading have lately been seen in the Royal Waterloo Hospital.

CASE 1.—A healthy girl of 18 was admitted for investigation. In infancy and early childhood she had had only measles, pertussis, and chicken-pox, and no infective diarrhœa. At the age of 12 she had a sudden attack of rather prolonged diarrhœa, resulting in general weakness, but without vomiting. The attack subsided, but was soon followed by others. Usually starting at the beginning of the day, they lasted not more than a week, after which the bowel function was normal. Periods of freedom gradually became longer, and she was often free for 2-3 months. But ordinary palliative treatment was of only temporary avail, and did not prevent recurrence. Puberty was passed through normally.

She first came to the hospital in April, 1935, complaining of attacks of sharp pain in the right iliac fossa, which was attributed to a calculus in the right ureter, which had passed naturally. At this time she thought fit to describe her bowel function as normal. At the beginning of this year she had her worst attack of diarrhœa. This, as usual, started suddenly in the morning; she had eight stools within the first hour, and surmises she had about 20 stools that day. They were looser than usual, but otherwise did not appear abnormal. There was some urgency of defecation. She had nausea but no vomiting, and no blood or slime was passed. The attack subsided fairly quickly, but left the patient weak. She was seen on Jan. 28th, 1936, two days after the onset, and was admitted for investigation. She had discovered that attacks commonly followed ingestion of eggs and fruit, or much meat.

She was an apparently healthy girl and apyrexial. Pulse-rate 86. There was no diarrhœa on admission. The only positive abnormal finding was caries of some teeth. Stools during this non-diarrhœal period appeared to be normal in formation and colour, and the average number without aperients was one per day. There was no pain on movement of the bowels. The abdomen showed no distension, tenderness, or rigidity. The spleen was not enlarged. Rectal examination revealed nothing unusual. Culture of the stools in this non-diarrhœal stage, reported by Dr. F. A. Knott, showed normal *Bacillus coli* and enterococci, and also numerous non-lactose-fermenters, whose sugar reactions coincided with those of *B. asiaticus*. The patient's blood agglutinated this organism up to 1-100, with no agglutination to T.A.B. groups.

While in hospital she was treated with a light non-residue diet, and acidophilus milk half a pint a day. Saloi was given in 5-grain doses twice daily. There was no recurrence of diarrhœa; she was discharged free of all symptoms and is being kept under observation.

CASE 2.—A boy, aged 5 years, was treated for rickets at the age of 2 as an out-patient, since when, his mother said, he had not been the same child. Nine months ago he had a sudden attack of diarrhœa, passing 6-7 loose,

green, slimy stools a day, without any other symptoms. The diarrhoea moderated after a few days to 4-5 loose normal motions a day. He was treated for three months by a practitioner without improvement, and eventually returned to hospital when faecal incontinence began at night. The stools were apparently so loose that they escaped in his sleep without the child being aware of it. No worms had been noticed. He had been incontinent of urine since the age of one year. Recently the motions had diminished in number—2-4 per diem. The mother stated that these were not abnormal except in their looseness. It had been noticed that fruit was especially liable to increase the diarrhoea. Tonsillectomy had been performed a fortnight before admission. The father is a sergeant, who had served in Gibraltar; there is otherwise nothing in the family history. The child was admitted for investigation.

He was a thin, though healthy boy. Weight 2 st. 8 lb. Multiple boils were present on the right side of the head, and the scalp was infected with nits and pediculi. During the first week he had 2-3 loose stools per day, and once had incontinence of faeces. There was also enuresis. Bacteriological examination of the stools by Dr. Knott on Jan. 10th, 1936, showed *B. coli* and enterococci, and numerous colonies of non-lactose-fermenting organisms, giving the reactions of *B. asiaticus*. On Dr. Knott's suggestion he was treated with acidophilus milk, but it was difficult to get him to take it. Pneumonia developed in February, 1936, and though the child was constipated during the infection, when the attack subsided, as it did by crisis six days later, he had 4-5 stools per day. He was put on acidophilus milk again—half a pint per day—on Feb. 4th, and on this date Dr. Knott reported that *B. asiaticus* was still present. The number of stools began to decrease rapidly at the end of the first week, and since then the child has had only a single normal stool each day. A few phlyctenules appeared in both eyes on

Feb. 14th but rapidly disappeared. The Mantoux reaction was positive. Since recovery from the pneumonia the child has rapidly improved in physical condition, and on Feb. 21st Dr. Knott reported that all cultures contained *B. coli* and enterococci only; no non-lactose-fermenters were present.

Infection with *B. asiaticus* is described<sup>1</sup> as beginning with malaise, headache, and rise of temperature of half a degree. The stools are usually solid, though dysenteric symptoms, with mucus and blood, occasionally mark the onset. Emaciation is common, while the "typhoid condition" is seldom met; the spleen is not always enlarged. This is an account of the acute condition. The cases we describe, however, seem to be of a chronic type, and the high agglutination titre in Case 1 suggested a chronic infection. Such a condition must be uncommon, for we have been able to trace no other account of it. There was no similar illness in either of the patient's families. The interest of the cases lies in the fact that *B. asiaticus*, a member of the parenteric group, apparently gives rise to chronic intractable diarrhoea, both in adults and children. The diagnosis can be made only by bacteriological examination, confirmed by serological examination. In both our patients treatment with non-residue diet and acidophilus emulsion seemed to have an almost immediate effect.

We would like to express our indebtedness to Dr. J. O'Reilly for details of the second case and to Dr. Knott for much help in the bacteriology of these cases.

## MEDICAL SOCIETIES

### MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY

At a meeting of this society held on May 7th the chair was taken by the president, Dr. BEVAN BROWN, who introduced Dr. Alfred Adler and commented on the increasing importance of the subject of individual psychology. Dr. ADLER spoke on the

#### Psychological Approach

When, he said, in the 'seventies of last century Wundt had established his chair of psychology at the University of Leipzig he had been asked if such a chair could not be established in every university. He had answered "No because each psychologist has his own psychology." The position was much the same to-day and Dr. Adler himself preferred an eclectic view. Some took the introspective course, others studied life situations, and yet others considered instincts or drives or other unconscious contents. To Dr. Adler the inside was part of the whole and the whole was greater than its parts; he had tried to understand how an individual reacted and what were the outside problems to which he related himself. In early childhood, when the child had to use his inherited abilities to solve the problems set in front of him, he developed a certain style of life and thereafter he always brought those same melodies or motifs into all life's situations. The method of approach to the life style was much like that of a detective; the psychologist had to study how the patient listened, talked, smiled, or sat down, his conscious acts and aims, and his relations with outside persons and problems. Every child built

his style according to his opinion of how to be successful when confronted with problems, but different people put different interpretations upon the word "success." It was essential to show that the motif was present in every phase, even perhaps in trance, before recognising it as the life style.

The three great problems of life were social relations, occupation, and love; these three contained all others and were unavoidable. They demanded for their solution a certain degree of social interest, which arose primarily from inherited qualities. Nevertheless, the inherited capacity for social interest must be trained, cultivated, and made alive. A man might be unable to solve the problem of friendship because he was not sufficiently interested in friends. He might then become afraid of people, afraid of life, feeling as if he were in a hostile country, and develop an anxiety neurosis. At the first interview the individual psychologist inquired about early home circumstances and about the origin of the present complaint. No symptoms would originate unless a patient was confronted by a social problem for which he was not prepared. A point in childhood could always be found at which the development and cultivation of social interest was blocked; it might be an apparently trifling one but it affected the life style. The personality must then be explained to the patient, and he must be shown how and why, at every point in his life, he had taken a mistaken direction. He must be given a chance to prepare better, and to increase his social interests. Neurotic people wanted to believe that life had something to give them, that the mountain would come to them and not they to the mountain. The individual psychologist ascertained the position of the child in the family and his earliest recollections. Much of

the relation of the patient towards his parents and towards life could be deduced from his earliest recollection. The same melody could also be recognised in dreams. The psychologist who understood his patient could guess what dreams he would have. The trained worker could find the life style in a quarter of an hour, but this was not to say that the patient had also realised it in that time. The treatment put him in a new situation and thrust him forward to face a problem which had already frightened and shocked him. He was not in love with his illness, but it gave him an alibi or excuse for his failure in life.

After a large number of questions had been asked

and answered, Dr. H. O. WOODCOCK expressed the thanks of the meeting to Dr. Adler and said that what Dr. Adler had done for individual psychology most of all was to live it. He did not criticise other schools; his unremitting energy was extraordinary, and he had real social feeling. Individual psychology, though not a substitute for religion, could, if its principles were generally adopted, banish both crime and international strife.

Dr. ADLER, in reply, reminded his hearers that individual psychology imposed on everyone who was interested in it an obligation to do something about it and not to expect, like pampered children, that others would do the work.

## REVIEWS AND NOTICES OF BOOKS

### Detachment of the Retina

*Operative Technique in Treatment.* By J. COLE MARSHALL, M.D., F.R.C.S., Senior Surgeon, Western Ophthalmic Hospital, London. London: Humphrey Milford, Oxford University Press. 1936. Pp. 80. 7s. 6d.

SINCE the theory and treatment of detached retina was put on a firm basis by the late Prof. Gonin a multitude of articles have been published dealing with isolated parts of the problem but until now no adequate account has appeared of the best contemporary methods of diagnosis and treatment. Mr. Cole Marshall has filled this gap in his book with considerable success. Most recent advances in technique have been devised by surgeons practising on the continent of Europe, and as the author has made it his business to become personally acquainted with their clinics, and indeed has dedicated his book to his colleagues abroad, it contains just that information which less mobile ophthalmic surgeons in this country are likely to require. The essential point in diagnosis is always the location of the hole or tear and the corresponding point on the sclera where the instrument chosen to effect its obliteration has to be applied. The most modern methods of doing this are described, and the author's own chart for comparing the various diameters of the globe with the insertion of the external eye muscles is reproduced.

In discussing the various types of operation employed, Mr. Cole Marshall tries to give credit to the merits of each. Although Gonin's original method of thermo-puncture has been practically given up in England, he thinks it may come into use again in certain cases. When it is possible to localise the tear with exactitude the method has the great merit of simplicity and, according to Gonin's own account, the only times when he had trouble was when the cautery was held in too long after the perforation of the sclerotic.

Since 1930 many alternative methods have been employed, the principal ones being associated with the names of Neve of Utrecht, Larsson of Stockholm, and Safar of Vienna. They are all methods of causing coagulation of the choroidal and retinal tissues at or near the site of the tear or hole, generally combined with small punctures to evacuate the subretinal fluid. This last is the method which Mr. Cole Marshall himself has consistently used at the Western Ophthalmic Hospital for the last four years, and a detailed description of the operation will be found in this book. It must be remembered that the introduction of this method of treating

retinal detachment is still recent and that the evolution of the operation is as yet incomplete. To those engaged in the process of perfecting it Mr. Cole Marshall's book will assuredly bring encouragement and stimulation.

### Pollen Grains

*Their Structure, Identification, and Significance in Science and Medicine.* By R. P. WODEHOUSE, Ph.D., Scientific Director of the Hayfever Laboratory, Arlington Chemical Company, Yonkers, New York. London: McGraw-Hill Publishing Company. 1936. Pp. 574. 36s.

THE first part of this monograph traces the development of knowledge of the physiology and morphology of pollen grains from the hand pollination of the date-palm in 885 B.C. to the gradual accumulation of information which has resulted from the researches of the last 150 years. After the historical section come examples of the application of this pollen knowledge—notably in the diagnosis and treatment of the pollen fevers and in a method of botanical and geological research, of which an account is contributed by Prof. Gunnar Erdtman of Stockholm. The largest portion of the book, almost two-thirds of it, is devoted to the description and classification of pollen grains and the methods of recognising them. Dr. Wodehouse points out that this account is very incomplete and that his main object is to furnish a reliable introduction to a complex subject.

The hay-fever chapter, which for medical readers is the slice of ham in a rather thick sandwich, is not entirely convincing. Dr. Wodehouse's idea of treatment is first to take a pollen census, so that "the exact species of pollen which affects the sufferer can be discovered by the hayfever specialist by the skin reactions." The pollen is caught for this census on glycerinated surfaces (in the manner devised by Blackley and described in his famous monograph published in 1873), and a sample census taken at Yonkers in 1933 is given us. It is only, of course, the wind-distributed pollen which gets caught, and the great bulk of this comes in the first half of the year from trees—chiefly the birch and oak; in fact "at the time of the oak-pollen maxima the atmosphere is actually hazy with oak-pollen." The second largest pollen group comes from the wind-pollinated compositæ in the autumn, and here, as is natural, ambrosia-pollen (the American "rag-weed") makes by far the biggest showing. Then, less than either the trees or the compositæ, the grasses make their mark on the chart at midsummer. What Dr. Wodehouse calls rather confusingly "tree-pollen hayfever"

produces only trivial symptoms in America as in England; it is the grass-pollen at midsummer that causes true hay-fever in both countries. The big splash of ambrosia-pollen on the Yonkers chart marks the duration of the autumn pollen-fever well known to be prevalent in North America. Happily this ghastly weed does not grow on our side of the Atlantic, therefore our autumn "hay-fever"—derived from Michaelmas daisies and such-like of the compositæ—is almost as insignificant an affair compared with our true hay-fever in June as is our tree-pollen fever in the spring.

In discussing his graph, Dr. Wodehouse draws attention to the fact that Timothy grass "in spite of the great emphasis that has been laid on it in most hayfever literature" stands only fourth among the grasses for Yonkers. The point is immaterial because Timothy grass was selected 25 years ago for hay-fever work, not so much because it might possibly stand first in any pollen census, but because it was in many respects the most convenient grass to work with, and was found to be antigenically identical with hundreds of other English grass-pollens, and presumably with grass-pollens all over the world.

A special feature of the book, which is beautifully got up, is its illustration by the fine free-hand drawings made by Dr. Wodehouse of the grains and of their special diagnostic features. This part of the work is admirably done and should be of the greatest help to those wishing for any reason, botanical or medical, to make a pollen census.

### Traité d'embryologie des vertébrés

By A. BRACHET, Professor in the University of Brussels. Second edition, revised and completed by A. DALCQ and P. GÉRARD, Professors in the University of Brussels. Paris: Masson et Cie. 1935. Pp. 690. Fr.130.

THE first edition of this book appeared in 1921. Albert Brachet had begun work on the second edition in 1930 when his death left the reissue of his book—which had become recognised as a classic—to be completed by two of his former colleagues in the University of Brussels. Much research has been done in embryology in the last fifteen years, especially on the experimental side, and the appearance of the second edition of this work has been awaited impatiently: its wide field and its erudition make it a medium suited to reflect with discrimination the new lights which have been appearing on every side of the older embryology.

In the early parts of the book, penned by Brachet himself, there is good evidence that the new conceptions arrived at through experimental embryology were well received. He saw crystallised the forces of embryogenesis, and recognised the relations to these of principal and subordinate organisers. One gets the idea that the cell, as such, has receded from a foremost position in his mind, and that if he had lived he might have become a definite supporter of the "Einheitstheorie" or of some such biological conception. Profs. Dalcq and Gérard have done well the difficult task of completing the work. There has been some shifting of chapters, with introduction of new headings and new material, but the general planning remains unaltered. The chapter dealing with primary and secondary gonocytes, and the associated theories, provides an excellent summary of recent views; additional matter has been inserted here dealing with the placenta and foetal membranes.

Of more general and fundamental matters, the

consideration of Vogt's experiments on amphibian eggs and of the streaming phenomena of their protoplasm, and the accounts of experimental work on the organism as a whole and of the accepted positions of preformed areas, are all of first-rate importance. The same may be said of the description of Conklin's work on the prochordates, which shows them to resemble closely the developing amphioxus. In this connexion it is of interest to notice that the writers define gastrulation as the "ensemble" of processes leading to the formation of an archenteric cavity and the putting in position of the formative material of the principal organs. This is a decided advance on the usual physical conception of gastrulation, one which would seem to follow on the recognition of the streaming movements of protoplasm and the changes in the areas of preformation.

We welcome cordially this excellent book.

### Sacrifice to Attis

*A Study of Sex and Civilisation.* By WILLIAM A. BREND, M.A. Camb., M.D., B.Sc. Lond., Lecturer on Forensic Medicine, Charing Cross Hospital. London: William Heinemann Ltd. 1936. Pp. 350. 10s. 6d.

Dr. Brend writes emphatically on the relations between sex problems and the development of civilisation, a particular motive inspiring him being the decrease in the birth-rate of our country. This decrease is viewed by some with satisfaction, having the terrors of overcrowding and unemployment in their minds; others prophesy our subsidence from the category of first-class nations, as a result of the failure of man-power; a third section of thinkers inquires what of that, seeing in imperial expansion, with its implications, a threat to individual happiness. Clear thinking is necessary to understand the arguments behind these views and to such meditations this outspoken book will contribute. It is thoroughly revolutionary and will thus give offence in some quarters through the criticisms of Christianity and the attribution to Christian teaching of misery due to the biblical conceptions of sex, and the precepts of the saints and early fathers. The author analyses the references to sex in the Gospels and discusses the psychology of the great apostle to the heathen, finding that it was particularly St. Paul who gave to Christianity an anti-sex bias, though similar doctrines were inculcated by the Greek philosophers, Buddha, and that curious Jewish sect the Essenes, pious communists who repudiated sexual union save when contracted for the sake of posterity. Dr. Brend employs the same frankness in dealing with the developments exemplified to-day in communism and fascism; and with the social codes in various countries appertaining to marriage, abortion, prostitution, and the publication of obscene writing, and he ends with a plea for freedom of thought upon these subjects. "The proposals in this book," he says, "involve setting up a standard of conduct based upon knowledge and truth, and not upon revealed guidance or sectional interests. They would take man as he is and fit a moral code to him, instead of torturing him to comply with a predetermined ethic." This is a fine ideal, and Dr. Brend is eloquent in his views for its attainment.

The title of the book refers to a custom in the worship of the Phrygian god Attis. Here castration was undertaken by the priests who were vowed to celibacy, the ritual forming an extreme example of sex repression.

### Surgical Emergencies in Children

By H. C. EDWARDS, M.S. Lond., F.R.C.S. Eng., Surgeon and Lecturer in Surgery, King's College Hospital. London: Baillière, Tindall and Cox. 1936. Pp. 274. 12s. 6d.

It is difficult to know what kind of reader Mr. Edwards had in mind when he wrote this little book. The specialist may find it is too small to cover such a large field and the general practitioner may regret that there is not more emphasis on diagnosis and less on treatment. It is a fact that some conditions which were previously looked upon as emergencies are nowadays treated more conservatively, a preliminary period of rest and inquiry being often considered advisable. Thus it is with empyema and perhaps even with osteomyelitis. Hæmorrhage and respiratory obstruction remain two grave events calling for immediate action; Mr. Geoffrey Bateman considers these separately in a chapter of 50 pages contributed to this book. General anæsthesia and modern basal anæsthetics are discussed by Dr. Vernon Hall who preserves a nicely balanced judgment.

The rest Mr. Edwards has written himself and it is his own opinions which he sets out. These do not always conform with the practice of most modern surgeons—for example, the "copious wet dressings" advised for compound fractures and the advocacy of open operation on all fractures of the humerus with musculo-spiral paralysis. He favours Winnett-Orr's method of vaseline packs and plaster-of-Paris in osteomyelitis; there is no reference to the important work of the late Clarence Starr which has largely influenced recent views of this condition. The urinary tract deserves better notice than it can receive in six pages, but even in this short space room might have been found for mention of calculus and paraphimosis.

The largest section is devoted to the abdomen and this is certainly the best part of a work which attempts to cover a very large subject in small compass. Here Mr. Edwards succeeds in giving a clear picture and clear advice on a difficult topic. It is almost impossible for a book like this to be completely successful, but few important surgical emergencies are ignored and the study of this book should give confidence to the inexperienced young surgeon likely to be called on for night work. It is written in a pleasant style and is easy to read. Miss Barclay-Smith's drawings are an attractive feature.

### Quarterly Journal of Medicine

THE April issue (Vol. V., No. 18) contains the following papers: R. Ewart Jones and D. Leyton Woodhouse (Birmingham) have examined 450 sera by the modified vanadate serum malignancy test (Bendien-Lowe). The 296 patients tested had a variety of malignant tumours and other pathological conditions. In 75 per cent. of the cases the test gave results corresponding with clinical observations and 4 cases are quoted where results agreed with post-mortem or operation findings where the clinical evidence had been contrary. Jones and Woodhouse discuss fully the cases in which it seems to have failed, and they also include a preliminary report on the results of the test in animals bearing experimentally induced neoplasms.—Investigating the production of the cerebro-spinal fluid, Henry Cohen (Liverpool) has studied the comparative values in blood and cerebro-spinal fluid of sugar, non-protein nitrogen, and inorganic phosphorus; he finds no relationship between these values, even when all known disturbing factors have been eliminated. He discusses his findings in relation

to the physicochemical and secretory theories of the formation of C.S.F. and indicates further lines of approach.—The same writer, together with Julius Libman, has inquired into two aspects of hyperglycæmia. An attempt was made to obtain hyperglycæmia over so long a period that its effect on the C.S.F. sugar could be noted, and this was achieved by combined administration of glucose orally and Infundin subcutaneously; infundin alone had no effect. They were able to show significant rises in C.S.F. sugar in sustained hyperglycæmia, thus proving incorrect the theory that the choroid plexus prevents the passage of glucose. There were signs, however, of a "threshold" effect.—These workers also showed that the glucose content of the C.S.F. after withdrawal from the body remained unaltered for an indefinite period provided it was sterile.

F. T. Nattrass and S. F. Evans (Newcastle) give an account of the production of pyrexia by means of short radio waves and demonstrate its advantages over other methods in that the pyrexia can be controlled and regulated. They discuss the development of electrical methods, describe an apparatus, and give details of the technique. The therapeutic use of short radio waves is illustrated by observations on cases of various kinds.—The value of quinidine in restoring normal rhythm in the presence of auricular fibrillation is well established, and there is fairly general agreement about the type of case in which it is useful. Maurice Campbell and F. W. Gordon (London) have made a detailed study of quinidine therapy and find that given a careful selection of suitable patients it is effective and often lasting in its effects. They have followed up a series of patients and estimate the duration of normal rhythm in different types of case. They report their experience with 91 patients during 1929-34, including a group with goitre.—Eleanor Badenoch and Noah Morris (Glasgow) have studied carbohydrate metabolism in cases of coeliac disease. They found a very flat blood-sugar curve during the active stage of the disease and considered this to be due to carbohydrate fermentation. They then investigated the possible connexion between the anterior pituitary and coeliac disease, since it had been suggested that the anterior pituitary hormone plays an important part in the regulation of sugar metabolism. They found that injection of anterior pituitary extract into patients with coeliac disease raised the level of the fasting blood-sugar and led to a slight improvement in the percentage absorption of fat.

S. L. Langley, W. Mackay, and L. Stent (Salford) have studied pneumonia with special reference to agglutinins. They find that these are recognisable in the blood-serum of the patient during the course of lobar pneumonia, where the infection is due to Type 1 or 2 organisms, and that their appearance is closely connected with recovery since they are absent in the majority of fatal cases. They also establish several other observations important from the point of view of treatment which if confirmed might, they think, be of more general application.—L. S. P. Davidson and J. Smith (Aberdeen) have made a clinical, chemical, and bacteriological study of 40 cases of Weil's disease among fish-workers in Aberdeen. They give proof of the occupational nature of the disease and its association with an industry housed in a particular area of the city, and they establish the connexion between the carriers (infected rats) and the sufferers (infected fish-workers) through contaminated water and slime. The prophylactic value of hypochlorite solution in spirochaetal disinfectants is examined.

EAST SURREY HOSPITAL, REDHILL.—Subscribers are badly needed at this hospital as the total deficit on the year was £713. About £7000 has been received towards the £11,000 required to erect a new nurses' home. Building will probably begin in June, and it is hoped that the new home will be ready in the spring of next year as the chairman declared the old one could no longer be tolerated.

# THE LANCET

LONDON: SATURDAY, MAY 16, 1936

## POISONS AND THE PRESCRIBER

THE first day of May was an important date for all who are concerned in the distribution of poison; on that day came into operation the rules made in pursuance of the Pharmacy and Poisons Act, 1933, and these rules affect the conduct of every type of person who is identified in any way with transactions in substances which are poisons within the meaning of the Act. Of course the pharmacist is chiefly concerned in carrying out these new regulations, but in a lesser, but by no means small, degree the medical practitioner, the hospital, the dentist, and the veterinary surgeon come within their scope and will be compelled to use new methods in buying poisons and in prescribing them. They will have to take pains to learn which substances are poisons, and even to be sure about that will need considerable care. There were drugs which on April 30th could be bought and even sold with the same freedom as milk and eggs, and on the next day the traffic in them became as circumscribed as is the traffic in the deadliest poisons known to mankind. Take one instance, to wit amidopyrin; for years past this substance has been an ingredient of proprietary articles advertised in the press as vitalising forces which make the old young, grey hair black, and pale cheeks red. As from May 1st amidopyrin will still have the same properties as it always had, for no poisons law can alter them, but the searcher after eternal youth will have to see a doctor about it. For amidopyrin, whether by itself or mixed in other substances may be sold by retail only on a written prescription. In this way will come to fruition the kind of patient research, always going on, which discovers substances as good as amidopyrin but without its drawbacks. And what has been said of the restriction to the sale of amidopyrin applies equally to barbituric acid, dinitrophenols, phenyl and salicyl cinchoninic acids, sulphonal, and any preparation containing them.

Poisons law is extremely intricate; it was so before the Act of 1933, and since that came into force it has become much more so. The intricacies are laid bare in Mr. LINSTEAD'S guide<sup>1</sup> written at the request of the Pharmaceutical Society of Great Britain, of which he is secretary. Two pages of this book are filled with the titles of statutes,

statutory rules and orders which bear directly upon the sale of poisons in this country; 30 items in all, from which it will be seen how necessary it is for someone in authority to simplify the law to the non-legal mind so that the letter of it may be observed. The new rules, as they apply to medical practitioners, are explained by Mr. LINSTEAD in clear terms, and notes are added for the guidance of those who prescribe or dispense medicines or do both. There are, first, certain poisons which can be sold only on a medical prescription and it is provided that the prescriber in such cases must enter on the prescription (1) his signature, (2) the date, (3) his address, (4) the patient's name and address, (5) an indication of the total amount of medicine, and (6) the dose. These requirements entail no departure from custom, but they now become enforceable in the case of certain drugs and the onus is on the dispenser to satisfy himself that the prescription is in the correct form. Further, the prescription may be dispensed once only, unless the prescriber has ordered otherwise, either on the prescription the number of times it is to be repeated or with no indication of the number of times. In the latter case the prescription is valid for an indefinite number of repetitions.

The rules as they apply to the obtaining of supplies by medical practitioners of substances which contain poisons included in the First Schedule require that a written order be signed by the practitioner, unless he attends at the premises of the supplier and signs the Poisons Register; there are no formalities to be complied with by a practitioner wishing to obtain substances which contain poisons which are not included in the First Schedule. There is a provision by which a practitioner may obtain substances in the First Schedule in an emergency, without sending a written order, if he gives an undertaking that he will furnish a written order within the next 24 hours. The seller must be "reasonably satisfied" that an emergency prevents the purchaser from furnishing the order or attending at his premises and signing the Register, and should the practitioner fail to supply a signed order he would be guilty of an offence against the Act. The conditions which apply to medical practitioners who supply medicines to their patients contain no provisions which make it necessary to keep a record of a medicine unless it is a substance included in the First Schedule. It is essential, however, for all medicines containing poisons supplied by a medical practitioner to bear a label on which appear his name and address. Further, if the medicine is an embrocation, liniment, lotion, antiseptic, disinfectant in liquid form, or other medicine for external application, it must, if there is poison in it, be in a container labelled with the name of the article—e.g., "The Embrocation," "The Liniment," with the addition of the words "For External Use Only." The only requirement about storage of poisons which applies to the premises of a medical practitioner is that the container must be impervious to the poison and sufficiently stout to prevent leakage arising from

<sup>1</sup> Poisons Law: A Guide to the Provisions of the Pharmacy and Poisons Acts, 1852 to 1933, and the Dangerous Drugs Acts, 1920 to 1932, for the use of pharmacists and others concerned in transactions in drugs and poisons. By H. N. Linstead, Secretary, Pharmaceutical Society of Great Britain. London: The Pharmaceutical Press. Pp. 444. 5s.

the ordinary risks of handling. It must not be assumed that Mr. LINSTAD's brief references to the new Poisons Rules as they affect medical practitioners will, valuable as they are, enable them to be sure they do not unwittingly commit a technical offence of some kind. The schedules of poisons under the new Act occupy ten pages of small type, while the list of poisons and substances to which special restrictions apply contains the names of some 1250 articles. It is only by patient observance of the art of literary condensation that Mr. LINSTAD has been able to limit himself to 444 pages. But no doctor can assimilate this compendious study without realising where he stands.

### SCARLET FEVER AND THE PUERPERIUM

SINCE the eighteenth century the attention of physicians and epidemiologists has been turned from time to time to the resemblances and the differences among those diseases which we now recognise as due to the hæmolytic streptococci—notably scarlet fever, septic sore-throat, puerperal fever, and erysipelas. At one time it would be the clinical peculiarities of this class of disease upon which discussion was focused; at another it would be their similarities and overlappings, clinical and epidemiological. At long intervals similar views have recurred in a striking manner: thus in maintaining the essential identity of septic sore-throat with scarlet fever, F. G. HOBSON has lately been expressing views<sup>1</sup> almost identical with those of WITHERING a century and a half ago. In our present issue Drs. BURTON and WEIR give an interesting account of another of the interrelationships of streptococcal disease. They describe three cases in which a scarlet fever rash developed in the puerperium and the uterus was infected with hæmolytic streptococci, the throat being apparently free from infection.

Modern study has done much to simplify the outlook on aberrant cases of streptococcal disease such as these. The scheme put forward by OKELL<sup>2</sup> in his Milroy lectures of 1932 seems to explain most if not all of the clinical and immunological entities of streptococcal origin occurring in the puerperium. OKELL recognises the following categories: (1) Faucial infection with rash—i.e., ordinary scarlet fever but occurring in the puerperium. (2) Uterine infection with a streptococcus of high toxigenic power in a Dick-positive woman, the throat being free from infection; this is manifested in a rash, complicated in some cases by the septic accidents which are only too common when a hæmolytic streptococcus invades the uterus. (3) Uterine infection in either a Dick-positive or a Dick-negative woman with a streptococcus of sufficient pyogenic and invasive power, but of low toxigenic power; the result here is a puerperal fever without rash. The same clinical picture is produced if the uterus of a Dick-negative woman is infected with a hæmolytic streptococcus which would be able to produce the picture given

under (2) if the woman were Dick-positive. One of these conditions may be combined with another and all may at times merge into the full picture of a septicæmia. BURTON and WEIR suggest that their three cases—which would be classified under (2) in the scheme given above—should be called puerperal surgical scarlet fever. The term seems hardly to be a happy one, though it emphasises the extrafaucial origin of the condition. There is nothing particularly surgical about many at least of such cases, and we immediately meet with difficulties if we imagine a woman suffering from scarlet fever of uterine origin transmitting her infection to the uterus of a Dick-negative ward-mate. There would be no rash in this second case and to call it scarlet fever at all would be to belie its description. Further instances could be brought forward to suggest that the study of streptococcal diseases is still suffering from a superabundance of names inherited from a time when a clinical analysis of the various conditions was alone possible. Many of these names have still a clinical usefulness, but they should not be allowed to obscure the essential unity of the diseases due to the hæmolytic streptococci, nor to discourage the observer from a deeper analysis of the pathogenesis of every case of such disease that he encounters.

As BURTON and WEIR point out, the prognosis of the scarlatinal syndromes of the puerperium is probably much influenced by the site of the infection, being best, no doubt, where there is a faucial infection only. It has long been recognised that under certain circumstances scarlet fever, or rather exposure to scarlatinal infection, may be a fatal complication of the puerperium, and outbreaks of severe and fatal puerperal fever have been recorded as starting in this way. That cases in which the prime focus of the infection is in the uterus may rapidly become septicæmic can be readily understood; and it is harder perhaps to understand how such a dangerous invader can enter the uterus and produce no worse effects than a relatively benign local disease with erythrogenic toxæmia, as in the cases BURTON and WEIR record. These occurred in the practice of one medical man between Sept. 24th and Oct. 18th, 1935, and had in all probability a common source of infection. That the infecting strain of streptococcus had high erythrogenic in-vivo toxigenicity and low pyogenic and invasive power may be deduced from the relatively benign course of the resulting disease from which all the patients recovered. An interesting feature of the cases is that faucial infection was a physical sign in all, though infection of the fauces was absent. It is well known that sore-throat may develop in children who have been given a sufficient dose of sterile scarlet fever toxin, and we must perhaps look upon the sore-throat of scarlet fever as of composite origin—as due not only to septic inflammation but also to the hyperæmia produced by the erythrogenic toxin. In studying aberrant types of scarlatinal disease it is important to remember that the presence of some degree of throat affection does not necessarily mean that the

<sup>1</sup> Hobson, F. G.: THE LANCET, Feb 22nd, p. 417.

<sup>2</sup> Okell, C. C.: Ibid., 1932, i., 867.

source of infection is in the throat. Many of such cases cannot be referred to their proper category without careful bacteriological examination.

## TUBERCLE AND SEGREGATION

It is not easy now to realise that tuberculosis has been dealt with seriously as a public health problem only since the turn of the century. It was at the British Congress of July, 1901, that ROBERT KOCH said: "The fact that tuberculosis is a preventable disease ought to have become clear as soon as the tubercle bacillus was discovered." And this pregnant remark of KOCH's led King EDWARD VII. to ask the historic question: "If preventable, why not prevented?" which fastened on the public conscience. In the same address<sup>1</sup> KOCH pointed to the danger of infection in small and overcrowded dwellings, and, since housing reform must take time, urged the removal of infective patients from them. The founding of special hospitals for consumptives he described as the most important measure in the combating of tuberculosis, and he pointed to the excellent example then already set in this country. We should not forget the service to the community long rendered by such friendly homes for the dying as Friedenheim (now St. Columba's) and St. Luke's, Bayswater. This fundamental message was overshadowed at the time by KOCH's avowal that he doubted the susceptibility of man to bovine tubercle; and it took his hearers long to discover the profound truth in the paradox. Five years later in his Nobel lecture KOCH again insisted<sup>2</sup> that the better provision for patients in the last stage of pulmonary phthisis has contributed more than anything else to the declining death-rate from tubercle. At that time, he said, more was being done in that direction than was generally supposed. In Berlin, for instance, during the decade 1895-1905 more than 40 per cent. of the cases of pulmonary phthisis died in hospitals, and although he did not underrate the value of the sanatorium in the restitution of the individual to a measure (at all events) of earning capacity, he pointed out that this restitution was no gain from the prophylactic standpoint. In this country A. NEWSHOLME has always stressed the same need insisting<sup>3</sup> that "institutional segregation, notably of advanced cases, is the most powerful single means available for controlling phthisis."

Notification was a necessary preliminary to action directed to prevent the spread of the disease. In the early days of the century a system of voluntary notification of pulmonary tuberculosis was sanctioned for particular areas. In 1908 compulsory notification of pulmonary tuberculosis was applied to patients treated under the poor-law; in 1911 compulsory notification was extended to patients treated by voluntary hospitals and similar institutions, and at the end of that year to the whole community. Finally in 1912 all forms of tuberculosis were made compulsorily

notifiable. During this period boards of guardians were encouraged to treat cases of pulmonary tuberculosis in their hospitals rather than to maintain them in their own homes, with the result that by 1911 some 9000 beds in poor-law hospitals were occupied by tuberculous patients. Public health authorities in whose areas notification was in operation developed a system of visiting and supervising notified cases living at home with a view to taking such steps and providing such facilities as would minimise the risk of the spread of infection. A number of public health authorities also made hospital provision to this end, while some of the more active authorities developed arrangements to provide for the treatment of patients with a view to their recovery. In 1912 too the first National Insurance Act came into operation which provided for the treatment of tuberculous patients of all types on a wide scale. The Inter-departmental Committee set up to advise on the application of this Act recommended the provision for adults suffering from pulmonary tuberculosis of one sanatorium and one hospital bed for every 5000 persons in the population, the hospital beds being intended mainly for advanced cases. Although no public authority dealing with tuberculosis has been given the power to require a tuberculous patient to enter or to remain in a hospital or sanatorium, much has been done by persuasion and by making the hospitals and their routine reasonably attractive. At the present time about one-third of the patients who die annually from pulmonary tuberculosis die in the residential institutions of public authorities. A number of authorities during the past six or eight years have developed a home isolation method of dealing with infective patients living in unsatisfactory home conditions. Under this system the patient and his family are provided with a cottage or small house which is sufficiently large to enable the patient to have a bedroom to himself. Financial assistance is usually given in respect of the rent and in return the tenant has to agree to certain conditions such as that the patient shall occupy a bedroom to himself, that no lodgers shall be taken, that the home conditions shall be systematically supervised by the authorities' nurse, and that the contacts shall be examined by the tuberculosis officer whenever he considers this to be desirable. The data are not yet sufficient to prove the value of this method statistically, but there is little doubt that the system is of definite service in minimising the spread of infection and in improving the health of the contacts.

This has been achieved without compulsory segregation such as was brought into operation in Norway in 1902 or in Thüringen two years ago. By the Public Health Act of 1925, however, any public health authority outside London was given power to apply to a court of summary jurisdiction for an order for the compulsory removal to hospital of a person suffering from pulmonary tuberculosis who is in an infectious state. London boroughs were able to obtain the same power, if they desired it, under a special Act in the following year; and Hackney promptly availed itself

<sup>1</sup> THE LANCET, 1901, ii., 187.

<sup>2</sup> Ibid., 1906, i., 1449.

<sup>3</sup> Trans. Epidem. Soc., 1905-06, xxv., 111.

of this power. The court in any case has to be satisfied not only that the patient is in an infectious state, but that his lodging or accommodation is such that proper precautions against the spread of infection cannot be taken or are not being taken, that serious risk of infection is thereby caused to other persons, and that a suitable institution is available for the reception of the patient. The order may be made for not longer than three months in the first instance, but may be renewed for a period not longer than three months. The

cost of the patient's maintenance must be borne by the authority applying for the order, and the authority may contribute or may be ordered by the court to contribute towards the maintenance of dependants. In practice it has rarely been found necessary to use this power. In cases of wilful neglect to take precautions the threat that an application for an order for compulsory removal will be made has nearly always proved sufficient to induce the patient to comply with the requirements.

## ANNOTATIONS

### NEW FELLOWS OF THE ROYAL SOCIETY

In previous years the names of the 17 men recommended by the council of the Royal Society for election at the next annual meeting were announced in February or March. This year it is not until the new Fellows have actually become entitled to add to their names the letters which spell recognition of scientific achievement that we are privileged to congratulate them. There are only two doctors in the list: E. H. Kettle, professor of pathology in the University of London at the British Postgraduate Medical School and consulting pathologist to St. Bartholomew's Hospital; and E. B. Verney, Sheild reader in pharmacology at the University of Cambridge, formerly professor of pharmacology at University College, London. Prof. Kettle has carried out researches on cancer, tubercle, and inflammatory reactions, and in recent years has been engaged in experimental work on the pneumoconioses and their relation to infection. Prof. Verney has studied experimentally the action of blood flow, nervous influences, and drugs on the secretion of urine, and has proved the continual control of kidney activity by the secretions of the pituitary gland. Among the other new Fellows there are two whose work is closely associated with medical problems: Lancelot Hogben, who holds the chair of social biology at the London School of Economics, has made substantial contributions to comparative physiology and to genetics; his work in experimental zoology has been chiefly concerned with the mechanism of colour change in amphibia and with the effect of hormones on the pigmentary effector system and the reproductive cycle of vertebrates. F. J. W. Roughton, lecturer in physiology at Cambridge, has worked mainly on the chemistry of respiration. He has developed methods for measuring the velocity of rapid chemical reactions, has applied them to reactions of physiological importance, and has calculated the speeds of such processes *in vivo*.

The other fellowships are distributed, as usual, over a wide range of scientific activity. A. C. Aitken is lecturer in mathematical statistics and actuarial mathematics at Edinburgh; J. D. Cockroft is demonstrator in physics at Cambridge; H. J. Fleure is professor of geography and anthropology at Manchester; C. Forster-Cooper is director of the University Museum of Zoology at Cambridge; and Sir Alexander Gibb is a consulting engineer who has contributed much to hydro-electrical developments in many countries. H. L. Guy is chief engineer in the mechanical engineering department of Metropolitan Vickers; H. G. A. Hickling is professor of geology at Armstrong College, Newcastle-upon-Tyne; and J. Kenyon is head of the chemistry department

at Battersea Polytechnic. N. F. Mott holds the chair of theoretical physics at Bristol, and R. G. W. Norrish a lectureship in physical chemistry at Cambridge. H. H. Plaskett is Savilian professor of astronomy at Oxford, E. F. Relf is superintendent of the aerodynamics department of the National Physical Laboratory, and Birbal Sahni is professor of botany at Lucknow.

### THE HEART IN HYPERPIESIA

IN a note on the cardiac complications of hypertension, Dr. Paul D. White,<sup>1</sup> assistant professor of medicine at Harvard, reviews 1249 cases which have come under his observation during a period of 15 years. In almost all of these the patients had essential hypertension (hyperpiesia) of several years' standing. Sixty-eight per cent. were between the ages of 50 and 70, the sex-incidence was almost equal, and the majority showed cardiac enlargement. Angina pectoris was seen in 329 (i.e., 26 per cent.) of whom 182 were men and 147 women. Coronary thrombosis occurred in 99 cases (8 per cent.) and the symptoms of congestive heart failure of greater or less severity brought 308 (25 per cent.) to the doctor. Rheumatic heart disease was present in 43 cases of which 23 showed mitral stenosis. Cardiovascular syphilis was noted in only 10 and thyrotoxicosis in 6. Aortic regurgitation without stenosis was found in 52 cases; aortic stenosis in 33. Dissecting aortic aneurysms were discovered at autopsy in 2 cases. Auricular fibrillation had developed in 170 cases, and in 55 of these was of the paroxysmal type; true paroxysmal tachycardia with regular rhythm occurred in 58. Electrocardiograms demonstrated auriculo-ventricular block in 34 cases and interventricular block in 43. Analysis of the cause of death in 100 consecutive cases (65 male, 35 female) revealed that 95 died "cardiovascular-renal" deaths; in the vast majority of these there was a cardiac catastrophe of one sort or another, and only 6 died from apoplexy, 5 from uræmia, and 5 from infections. As regards age, 42 died between the ages of sixty and seventy, 26 between seventy and eighty, and 2 over eighty. Dr. White, who takes a grave view of hypertensive heart disease, points out that 72 per cent. of his patients died before the age of seventy. A more cheerful reading of the facts would be that 70 per cent. of them attained the seventh decade. He also urges more intensive research into the aetiology and therapeutics of hyperpiesia, and while agreeing with him we should remember that the expectation of life in proved cases of essential hypertension does not fall much below the normal figure, that the condition is extremely common, and that many hypertensives doubtless live to ripe ages and die with their hyper-

<sup>1</sup> New Eng. Jour. Med., April 9th, 1936, p. 719.

tension undiagnosed. Even so, routine sphygmomanometry can do nothing but good provided we are careful not to make our patients "blood-pressure minded" to the point of neurosis.

**APPARENT TRANSFORMATION OF A VIRUS**

VERY interesting relationships have lately been demonstrated between two viruses which attack rabbits in America. Both of them produce tumour-like lesions and have been considered as forming a possible link between the viruses which produce tumours and those of other groups. The virus of infectious myxoma, known for nearly forty years, causes a highly infectious, almost uniformly fatal disease in domestic rabbits, characterised by inflammation of mucous membranes and the formation of myxomatous masses in the skin and elsewhere. The other virus, that of infectious fibroma, occurs in North America among wild cottontail rabbits, members of a different genus from the domestic rabbit; it produces fibromatous nodules at the site of inoculation in either cottontails or tame rabbits, and is not infectious under ordinary laboratory conditions. Andrewes and Shope<sup>1</sup> have lately described a "mutant" of this fibroma virus which gives rise to inflammatory instead of tumour-like lesions, but is still not infectious. This "mutant" has appeared rather suddenly in the course of serial passages through tame rabbits, while virus carried through other series has retained its original characters.

Shope showed in 1932 that the myxoma and fibroma viruses were immunologically related, and this relationship forms the subject of several recent papers.<sup>2-4</sup> It has been found that the myxoma virus, contrary to previous belief, will infect cottontail rabbits, but that it produces in them only a localised lesion at the site of inoculation, recalling the infectious fibroma rather than the myxoma picture. Such cottontails are subsequently found to be immune to both viruses. After serial passage through cottontails, the myxoma virus fully retains its power to produce a generalised fatal disease in tame rabbits. When fibroma virus is injected into domestic rabbits, the tumour-like growths regress in course of time. If myxoma virus is now inoculated into these animals, they are found to be partly resistant and the virus produces as a rule only localised lesions as it does in the cottontail. It will nevertheless multiply and can be propagated serially in such rabbits. These facts may be briefly set forth as follows:—

virus is antigenically the more complex. Following up this clue, Berry and Dedrick<sup>5</sup> carried out experiments, based on the work of F. Griffith, on transformation of one type of pneumococcus into another. It will be recalled that Griffith in 1928 degraded type-specific pneumococci to the rough form and was then able by inoculating them into mice along with killed virulent pneumococci of another type to cause them to develop into the smooth virulent form of that other type. The same result was later obtained in vitro by Dawson and Sia (1931) and Alloway (1932). Berry and Dedrick similarly heated myxoma virus to a temperature of 60° or 75° C.—the last figure being well above its thermal death-point—and inoculated it into rabbits along with living fibroma virus. They report that in each of eight experiments rabbits receiving the mixture died of myxoma; typical myxoma virus was recovered from them, and the disease proved infectious by contact. Though only a preliminary report is as yet available, it seems that the experiments have been adequately controlled. The authors suggest that there is something in the myxomatous material which lends virulence to the fibroma virus, and, further, that this something is propagated along with the virus in future generations; in other words, the fibroma virus is transformed into myxoma virus. Other possible explanations will have to be sought, but the line of approach may well, as Berry and Dedrick suggest, prove useful in exploring other virus relationships.

It is a strange fact that tame rabbits, which are derived from the European wild rabbit, should be naturally attacked by myxoma virus only in America, where they are not native. The facts now coming to light concerning the relationships between myxoma and fibroma viruses afford a likely clue to the origin of the former. Further study of this problem may even open up the whole question of the evolution of viruses and the origin of apparently new ones.

**ST. GEORGE'S HOSPITAL**

St. George's Hospital has from its earliest days had an association with the Royal Family; indeed this has been continuous since 1734, when Frederick Prince of Wales became the first president. To-day that precedent is carried on by the Duke of Kent, who at the last annual Court of Governors alluded to the eight generations of his family "who have maintained their close interest in the hospital erected almost at their doorstep." The Duke spoke with appreciation of the preliminary work which has been done for the rebuilding fund, and hopefully of all that which is still to be accomplished. His remarks went home so well that at the close of the meeting one of his audience handed in his cheque for a thousand pounds, and within a day or two this was followed by one for fifteen hundred. A million pounds, which the hospital must raise, is a formidable sum, but repeated donations of this kind which have flowed in steadily since the appeal began are putting heart into those whose business it is to collect the money as the great deficit is slowly but surely worn down. An immediate need is two thousand pounds for an up-to-date X ray apparatus which has recently been installed but is still unpaid for, and for this purpose a great boxing tournament has been arranged. A dinner dance under the patronage of the Duke and Duchess of Kent demands patronage, while a race meeting at Northolt represents another activity of the appeal fund committee. It is not always that a hospital

	Normal cottontail rabbit.	Normal domestic rabbit.	Myxoma-immune cottontail.	Fibroma-immune domestic rabbit.
Myxoma virus.	Local myxoma or fibroma nodule.	Fatal disease.	Nil.	Local fibroma or myxoma nodule.
Fibroma virus.	Local fibroma.	Local fibroma.	Nil.	Nil.

Sera from myxoma-immune rabbits contain antibodies which neutralise both viruses; those from fibroma-immunes inactivate fibroma virus, but are less active<sup>4</sup> or inactive<sup>2</sup> against myxoma. It seems possible therefore that the more virulent myxoma

can capture a millionaire philanthropist ready to donate a large sum and until that happy day arrives for St. George's its supporters are relying on repeated efforts to secure many smaller contributions. The day may arrive soon or may be delayed, but until it comes endeavour must be constant, and all must wish it success and help towards the great achievement.

### POLLEN STATISTICS

A most fascinating account of a laborious method of investigation has been contributed by Prof. Gunnar Erdtman, of Stockholm, to a work on Pollen Grains reviewed on another page. He describes how by making borings to various depths in the peat bogs it is possible to reclaim and recognise the various pollen grains, and thus try to make some estimate of what plants, and in particular what trees, were growing in the various localities hundreds or even thousands of years ago. The method has its difficulties, as Dr. Erdtman is careful to point out: pollen may fly for hundreds of miles (e.g., from Canada to Greenland) and thus be caught in bogs remote from the vegetation which has produced it; the various pollens are produced in very different quantities by different plants, will fly very different distances, and, if they get on to a bog, are preserved in it to a varying extent. Again the finding of pollen to-day does not necessarily tally with the presence or absence of corresponding trees or plants; thus there is really no "pine-time" occurring in Alberta at the present day, though the pollen findings in Alberta bogs would certainly suggest the contrary. Still, to detect errors goes a long way to overcoming them, and Prof. Erdtman is convinced that his pollen statistics, if calculated from a great number of localities in different countries and then compared with each other, could yield results that would at least show the lines along which further research could profitably be conducted. It seems to us a little doubtful whether the labour involved in such investigations would prove to have been well directed.

### MORE PEP WANTED

THE Royal Society of Medicine has reached a stage at which everyone speaks well of it, including the Minister of Health. At the biennial dinner last week, reported on another page, Sir Kingsley Wood revelled in the fact that the society had nothing to do with medical politics, and he could therefore himself enjoy a night out. More than that, it provides the Minister with standards on which to model his work. It was left to the retiring president to find the only fault with the society's present conduct. Dr. Hutchison spoke of the three functions it had to perform—to supply the apparatus of knowledge, to provide for the interchange and diffusion of knowledge, and to promote good fellowship. All these functions he had found efficiently fulfilled. One thing however was lacking: there were many sections and they were well attended, but, he said, the discussions are too polite; and turning to the Minister he obtained his assent that unparliamentary language is at times a useful tonic. The fact is that at a certain stage of specialisation gatherings are apt to lose vivacity, so learned are the participants who attend the meeting with their case made out and the intention to let off what they have to say without reference to what has been said or what will be said. There is perhaps inevitably in such discussions a lack of the freshness met with at a rotary club meeting in which each member represents some different outlook on life and manners, or in a

society at which many different groups of medical practice are represented. Happily it is not the case that medical politics are rigidly excluded from all sections of the society, although this weakness may be attended with a sense of shame, for the press and even the medical press has several times been excluded on such occasions. But this may be going rather further than Dr. Hutchison intended, for he went on to quote an old Latin tag which says that "in order to speak the truth it is not necessary to pull a long face," and to welcome the increasing use of the society's house as a club and the increasing frivolity of the receptions held there. Perhaps what is most wanted is the ability for the introducer of a discussion not merely to read his paper, but, as Dr. Bruce Low suggested a year or two ago, to render and perform his contribution just as an actor performs a part or a musician renders a piece of music. It is not enough to garner his observations or to marshal the emergent facts; he must present them in a way to elicit discussion and even, as Dr. Hutchison suggested, to provoke retort.

### A CLEARING HOUSE FOR HUMAN GENETICS

FOR the last four years there has been a branch in this country of the International Human Heredity Committee founded by the International Federation of Eugenic Organisations. This has recently been enlarged as the British National Human Heredity Council and, in collaboration with the Galton Laboratory, aims at setting up a clearing house for material on human genetics. The council consists of a number of geneticists and leading medical men, with Prof. R. Ruggles Gates, F.R.S., as chairman, Sir Laurence Halsey as treasurer, Mr. J. A. Fraser Roberts, D.Sc., as hon. scientific secretary, and Mrs. C. B. S. Hodson as hon. general secretary. The direction of the work is to be in the hands of a small executive committee. The council, we understand, would be grateful to receive, from institutions and individuals, well-authenticated data on the transmission of human traits—e.g., family histories or pedigrees, twin studies, and statistical researches. Authors of published work may have collected a number of pedigrees which they have been unable to reproduce in detail. Such records by inclusion in the clearing house would be preserved. Anyone who wishes to have a copy of the standard international pedigree symbols may obtain one from the office at 115, Gower-street, London, W.C.1.

### THE ORIGIN OF CHILBLAINS

THE conception of chilblains as a manifestation of tuberculosis, or at least of the activities of the tubercle bacillus, is by no means new. Its latest exponent is Dr. Jeanne Stephani-Cherbuliez, of Geneva, and her thesis, published in *Revue de la Tuberculose* for March, is the outcome of thirteen years' observation. As she points out, Darier in the 1918 edition of his "Précis de Dermatologie" adumbrated the possibility of chilblains being some day recognised as a manifestation of attenuated tuberculosis, in the same class with the tuberculides. Calmette also suspected a causal connexion between the tubercle bacillus and chilblains. The author of the paper has dispensed with laboratory methods of research and has not even made systematic use of any tuberculin test. Instead, she has studied the incidence and severity of chilblains in various groups classified according as their constituent members were healthy or suffered from, or gave a family history of, tuberculosis. Of 350 persons examined, 250 were tuber-

oulous and 100 were healthy. In addition, there was a separate group of 15 patients subject to ulcerating chilblains. It was found that while chilblains were much commoner among the offspring of healthy parents than among the offspring of tuberculous parents, their course was more benign in the latter—a difference which Stephani-Cherbuliez compares with the observation that tuberculosis developing in previously healthy stock is liable to run a comparatively violent course. Chilblains, she argues, are an allergic response to the tubercle bacillus which itself may not be present in the chilblain but in some other part of the body where it may even play the part allotted to it by the Germans in their conception of the *Primärkomplex*. If this were so, chilblains might come to be regarded as a valuable warning—i.e., as evidence of tuberculous activities which demand that precautions should be taken by the patient lest worse befall him. But while none will deny that chilblains and tuberculosis are often associated, it will take much new evidence to persuade us that the association is essential.

#### SYMPATHETIC OPHTHALMIA AS A SEASONAL AFFECTION

No important advance has been made for many years in explaining the pathology of sympathetic ophthalmia. Our Budapest correspondent tells us of an elaborate study made by Dr. Bela Waldmann which was recently awarded the prize of the Oradea Medical Society. Dr. Waldmann believes that sympathetic ophthalmia depends upon some toxic agent conveyed to the eyeball from an accessory nasal sinus, and thence to the second eye via either the optic or the ciliary nerve. His belief is founded on the fact that out of 69 cases of which he has personal knowledge 53 started during what he terms the influenza months (October to April), while during the summer months (May to September) less than a quarter started. To test his theory from further statistics he sent inquiry forms to various eye clinics (in Baltimore, Berlin, Budapest, Ghizeh, London, Madras, Manchester, Munich, Stockholm, and Vienna), and by this means obtained answers respecting 124 additional cases and these told the same story. Three-quarters of the cases began during the cold half of the year and only one-quarter during the warm. In Prof. Meller's clinic in Vienna the ratio was 7 : 1. On the strength of these data Dr. Waldmann feels justified in asserting that sympathetic ophthalmia is a seasonal affection. This is a new observation and, whether or not his suggestion as to the channel of infection should ultimately prove to be justified, it is one that should not be lost sight of.

#### THE RELATIONS OF THE ŒSOPHAGUS

SURROUNDED by translucent lung tissue, the heart and aortic arch are favourably placed for radiographical inspection. But the posterior surface of the heart and the descending aorta, because of their proximity to the spinal column, are not always readily visualised. The Œsophagus, in traversing the thorax, is closely applied to the back of the heart, the aorta, and the tracheo-bronchial tree, so that its course is easily influenced by changes in cardiovascular structure. When filled with a suitable emulsion of barium, the Œsophagus serves as a valuable radiological landmark in the chest. Kreuzfuchs (1921) made use of the barium-filled Œsophagus in measuring the diameter of the aortic arch. Gäbert (1924) studied the displacement of the Œsophagus caused by enlargement of the left auricle, thus extend-

ing the anatomical investigations of Kovács and Stoerk (1910). Renander (1926), Biedermann (1931), and others noted the characteristic Œsophagogram associated with a right-sided aortic arch, a congenital anomaly which occasionally causes dysphagia. Parkinson and Bedford described in our own columns (1931, ii., 337) the middle Œsophageal impression, due to the left bronchus and indirectly to the right pulmonary artery, and discussed its clinical significance in relation to cardiovascular disease. A further valuable contribution to our knowledge of the Œsophagus in relation to the heart and aorta has been made by Dr. William Evans, in a report<sup>1</sup> issued by the Medical Research Council. Dr. Evans has made an extensive study of the normal Œsophagogram in healthy subjects, confirming his interpretations of the various impressions by anatomical dissection. He establishes four normal Œsophageal impressions made, from above down, by the aortic arch, the left bronchus, the left auricle, and the descending aorta. Each of these is described first as seen in healthy subjects, then as modified by different pathological changes in the heart and aorta. A large series of radiograms is given, each with its anatomical interpretation, illustrating in turn the different forms of Œsophagogram found in health and in cardiovascular disease. Dr. Evans's monograph, which combines with his own investigations a survey of previous work on the subject, should lead to a better appreciation of the importance of the visualised Œsophagus in relation to the heart.

#### THE BRITISH HEALTH RESORTS

THE waning popularity of the continental health resorts and the renewed vigour of their British rivals is referred to in the report on page 1137 of the conference of the British Health Resorts Association at Woodhall Spa. In his foreword to the Association's Handbook for 1936,<sup>2</sup> Sir Kingsley Wood writes: "It is true to say that the benefits which British Health Resorts can offer in a great variety of cases are not known or used to the extent they deserve. Modern research has done much to explore and explain the relation of environment to health, and to add to our knowledge of the precise importance of factors like climate, air, and medicinal waters in the treatment and prevention of disease. But this increased knowledge cannot have its full effect unless it reaches the public. It is the object of the British Health Resorts Association to ensure that it shall. The task which the Association has undertaken is threefold; to bring before the public the claims of British spas and watering places to possess curative resources in no way inferior to continental health resorts; to offer to the medical profession and its clients expert advice on the natural conditions most favourable to the successful treatment of the maladies with which they are concerned; and to inform them where these conditions may be found in this country." The handbook, now in its fourth edition as a separate work, ably serves all these purposes. Considerable changes have been made in the new and enlarged edition, which will increase its usefulness both to the general public and to the medical profession. The information about the British wintering places has been augmented by detailed meteorological reports on the climate during each of the winter months; these are in

<sup>1</sup> Spec. Rep. Ser. No. 208, pp. 93, 2s. 6d.

<sup>2</sup> British Health Resorts: Spa, Seaside, Inland. Official Handbook of the British Health Resorts Association. Edited for the Association by A. Fortescue Fox, M.D., F.R.C.P. London: J. & A. Churchill, Ltd. 1936. 1s.

addition to the readings hitherto given for the whole winter. These should help the physician to decide what resorts might help each individual patient who is likely to benefit from a change of climate. The 179 coastal resorts have been alphabetically arranged in one section and the maps and descriptions of the different climatic regions are grouped together in another. A third group includes all the recognised British spas, and, finally, an account of the waters and climates of Australia and of the West Indies has been added to the section on the British Commonwealth overseas. Each account of the spas and resorts is illustrated; the place itself, its climate and attractions are fully described, and indications for residence at it are given. The Association this month is beginning a systematic investigation of the claims of some of the more important resorts by means of a series of visits conducted by a sub-committee. This will supplement the more general information obtained in the conferences that have been held throughout the country during the past few years, and the further data obtained should in due course add to the value of what is already an excellent work of reference.

### THE TOXÆMIC ELEMENT IN INTESTINAL STRANGULATION

COLLAPSE and death following intestinal strangulation have been variously attributed to loss of fluid from the general circulation, to loss of chlorides, to nervous stimuli, and to toxæmia. It is only on strangulation of a long loop that there is likely to be much loss of fluid, and Mr. G. C. Knight and Dr. David Slome<sup>1</sup> have now come to the conclusion that toxæmia is alone of importance. Their experiments appear to show that the toxin is generated in the wall of the bowel, and is a product of degeneration of the tissues—due to the anoxæmia that follows interference with the local circulation—rather than of bacterial activity. The specific effect by which Knight and Slome were able to recognise the presence of the toxin in body fluids and extracts is a depressor action on the blood pressure. Their experiments included attempts to measure the fluid loss from a strangulated loop and by peritoneal exudation around it. In one of these, a cross-circulation experiment, an animal was made to bear all the fluid loss by connecting its carotid artery to the mesenteric artery of the strangulated gut of a second animal. Whereas the strangulation had a profound effect on the latter, which died rapidly, the blood pressure of the animal supplying the blood was steadily maintained. The method of strangulation was by ligation of the superior mesenteric vein. Another type of experiment was designed to make the normal animal bear the toxæmia. Here a loop of bowel 17 cm. long was strangulated; when it was black it was enclosed in a rubber bag, and at the end of 16½ hours this contained 45 c.cm. of fluid. The fluid, together with the black loop of bowel, was then placed inside the peritoneal cavity of a normal animal, the abdominal cavities of the two animals being sutured together. The normal animal died, in circulatory collapse, within 3½ hours, although it had lost no fluid, while the strangulated animal died a little later, 20½ hours after the strangulation. The presence of depressor substances in the venous blood was demonstrated by cannulation of the superior mesenteric vein in cases of superior mesenteric strangulation, the blood being collected and injected intravenously into normal animals; a depressor action was obtained within an

hour of the strangulation. It was also proved that the depressor substance could be absorbed through the peritoneum when both venous and lymphatic channels were compressed—the most likely channel of absorption, probably, in strangulation in human beings. The contribution that distension of the gut wall makes to the collapse of the patient is probably very important, but its significance is not quite clear. It may be largely a nervous effect, though Knight and Slome incline to think that this is itself a result of further production and absorption of depressor substance.

### PHYSICAL MEDICINE

IN the art gallery of the Guildhall on Tuesday evening the City of London offered its inimitable hospitality to the delegates of the Sixth International Congress of Physical Medicine, in session this week in London. Captain G. S. Elliston, M.P., speaking on behalf of the public health committee of the City, toasted the Congress and recalled how careful the City of London had been, for 500 years or more, through the charters granted to the Barbers and Apothecaries Companies, in the protection of its citizens from the rashness of presumptuous empirics and ignorant and inexpert men; and he gave a particularly kind word to the latter society in maintaining a register of biophysical assistants qualified to dispense physical medicine on the prescription of doctors. Four delegates responded to the toast. Sir Robert Woods, president of the congress, insisted that for the first time preventive medicine had appeared on its programme in the shape of a section devoted to physical education. Sir Leonard Hill, a vice-president, claimed that 80 per cent. of patients who come for help to insurance practitioners have nothing the matter with them that is not amenable to physical medicine, and he asked the universities to found chairs in this branch of medicine, and the City to finance a National Institute of Physical Medicine. Prof. I. Gunzburg, of Antwerp, set out with eloquence the decadence of medicine and surgery as we know them and their replacement by physical methods which would constitute the medicine of the future. Finally, Dr. Richard Kovacs, of New York, speaking with facility in four languages, expressed satisfaction that the congress was meeting in London, for, said he, the real progress of science lies in individual liberty. The Lord Mayor, whose traditional part in all good health work was eulogised by Sir Henry Gauvain, after welcoming the delegates, put to them the searching question what was the present need for more radium, in view of his responsibility for some worthy object for the King George V. Memorial Fund. Earlier on the Tuesday the congress had met in common session, some account of which is given on another page, to resolve itself later in the week into seven separate sections, each with its own programme. The attendance is remarkable testimony to the hold which this new branch of medicine has on the minds of medical pioneers in all countries.

Dr. John Smith Fraser, who had for 15 years been surgeon to the Royal Infirmary, Edinburgh, and lecturer on diseases of the ear, nose, and throat, died in Edinburgh on Monday last.

On May 19th, 21st, and 26th Sir Bernard Spilsbury will deliver the Croonian lectures of the Royal College of Physicians of London, on the doctrine of inflammation. The lectures will take place at the College, Pall Mall East, S.W., at 5 p.m., and members of the profession will be admitted on presentation of their card.

<sup>1</sup>Brit. Jour. Surg., April, 1936, p. 820.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### C.—PROGNOSIS OF PSYCHOLOGICAL DISTURBANCES IN CHILDHOOD AND ADOLESCENCE

PSYCHOLOGICAL disturbances in the young may be manifest in a wide variety of symptoms. We are dealing not with diseases as a rule but with personalities in the making. Symptoms are usually evidence of disturbance of development rather than of distortion of established function. It follows that on the whole a favourable outcome is to be anticipated provided gross mistakes in treatment are avoided; for at this stage there is an opportunity to undo faulty tendencies with much less labour in retracing the line of development than is required in the treatment of psychopathological conditions in adults.

A considerable proportion of symptoms in childhood and adolescence can be considered as reactions to situations. In children the situations are often still present or at least recent; a large number of them have not become internalised or introjected. Hence what might be called environmental manipulation is far more often successful than it is in adults, just as it is much more practicable. It is easier and less costly, to take an extreme example, to change a child's school than to change in any worth-while fashion his job in after-life. Moreover, the people surrounding the child are much more amenable to education about him than are the persons in the vicinity of an adult. For the child allowances are more willingly made. Pedagogy is recognised, dimly perhaps, as a branch of science which anyone may have to practise and yet about which anyone may receive instruction without loss of dignity. In adult patients, on the other hand, personal feelings are even more involved than they are in one's relationships to children, and the weapons of prestige and affection are much less readily available in consequence.

This reciprocal plasticity both of patient and environment must clearly be an important factor in prognosis. But in so far as the environment enters into the causation of these psychological disorders of childhood it becomes itself an important factor to be weighed in giving a prognostic opinion. Moreover a child's environment is apt even more than an adult's to be a continuing cause of symptoms. In adult conditions, we hear much more of precipitating causes than of continuing ones, partly because in adults we are much more apt to think of diseases than of reactions. In children the continuing rather than the merely precipitating aspects of the environment are impressed on us very strongly, and never more strongly than when we watch the results of complete avulsion of the child from his surroundings: symptoms of a type that in an adult would be regarded as ominously chronic may in a child subside almost in a night and remain away indefinitely.

It is possible that some "symptoms," so-called, are simply normal developmental stages, in the sense that every child develops some degree of them at some time or other in the course of its natural growth. This for example may be true of obsessions and compulsions. Thinking of that order is normal at some stage: and only when it is especially prominent or lingers over-long can it properly be regarded as pathological, like a thyroglossal cyst.

It must also be remembered that when we speak of "symptoms" in childhood we are often misusing the word. Symptoms are by definition what the patient complains of, but in children they are much more often what the adult complains of as appearing in the child.

Self-rectification has also to be taken into account in assessing results: especially when claims are made for the superiority of one method of treatment over another. It appears to take a great deal to disturb a child psychologically in a permanent fashion; and although we must regard the old comforting assurance that "he will grow out of it" as thoroughly feeble in its motive (as it is so often a confession of ignorance about therapy) there is no doubt that children do have a very distinct tendency to "grow out of" their psychological difficulties. At any rate that is the impression which anyone must receive who studies psychological disturbances in children.

In an attempt to obtain a more precise impression an attempt was made some years ago in connexion with the Child Guidance Clinic at Guy's Hospital to find what was the apparent recovery-rate from psychological disturbances in children which had not been treated. This was undertaken with the hope of getting a control group for the results obtained in the clinic. Miss McFie found the results shown in the Table. Her figures give the number of

*School-children showing various types of difficulty classified according to result of school handling. (McFie.)*

School.	Personality deviation.			Behaviour disorders.			Habit disorders.			Scholastic difficulties.

X = Difficulty cleared up completely. Y = Difficulty cleared up partially. Z = Difficulty persisted.

Owing to the fact that some of the children presented more than one type of difficulty, an addition of the totals gives 416, while the actual number of children concerned is 322.

recoveries estimated by head mistresses and head teachers in children who while under their care exhibited symptoms of a nervous type. This, which might be regarded as a spontaneous recovery-rate, seems to be comparatively low compared with what would have been expected. The method of collecting the figures while it was the best that could be devised at the time, and was very conscientiously carried out, contained considerable possibility of error; but these are the only figures available to us of the spontaneous recovery-rate in the types of disorder now under consideration. They form at least an interesting contrast to what we have to state as the results of treated cases.

The problem which confronts us at the outset in making any prognostic generalisation on this topic is that of classification. There is no very widely

accepted simple classification but there are close resemblances between the different classifications in use. We have sought to put the classification upon as logical a basis as possible by compiling a list of symptoms in our series of patients. To give the experience with individual symptoms however would be of little value, as their meaning depends so much on their setting among other symptoms and indeed on their setting in the total problem. We have therefore used the list as a basis for subdivision, enumerating various symptoms under one of several headings into which they seemed to fall logically. One has to realise that when we speak of psychological disorders we have to include not only conditions which appear to have their origin at the psychological level, but others which may only have their expression there and which actually originate at a lower level, for example at the vegetative level. Thus it appears that some night-terrors at least are of metabolic rather than of psychological origin.

The classification which appears to us to be of the most practical utility is the one which, with some modifications, has been used at Guy's Hospital for a number of years. It includes the types of reaction met with also in adults, but adds other types of disorder which come specially to notice in childhood. This classification is as follows:—

1. *Disturbances arising at the vegetative level*—i.e., of a psychological symptomatic description but not accounted for by pre-existing psychological conditions. For example, disturbances in the functions of eating, sleeping, and excretion—e.g., night-terrors, groaning in sleep, restlessness, some cases of walking and talking in sleep, and some of enuresis.

2. *Habit disorders*—nail biting, thumb sucking, hair pulling, nose pulling.

3. *Behaviour disorders* (this refers to social behaviour of the purposive kind. Fidgetiness is therefore not included). This includes stealing, lying, truancy, wandering, sex misbehaviour, masturbation, disobedience, obstinacy, destructiveness, spitefulness, temper tantrums, crying spells, threats of suicide, swearing, refusal to eat, refusal to speak, refusal to go to school, dermatitis artefacta. The reason for including dermatitis in children is that in our experience it is a conscious purposive act (although of course the real factors may be unconscious).

4. *Personality traits*.—These are defined as habitual attitudes in a social respect, and include shyness, sensitiveness, sulkiness, a-socialness, greediness, irritability, petulance, excitability, timidity, and the opposites to some of these; aggressiveness for example, rebelliousness, and its opposite (easily dominated), over-meticulousness, dreaminess. It has to be pointed out that behaviour if continued long enough becomes ingrained as a habit and ceases to be consciously purposive. It then ranks as a personality trait, and there is therefore apt to be a transitional state between these last two categories.

5. *Scholastic difficulties* other than those due to generalised mental defect—e.g., reading disability. This category therefore includes backwardness in school arising from environmental handicap or intrinsic localised handicap such as word blindness and word deafness.

6. *Psychoneurotic anxiety states*.

7. *Hysteria*.

8. *Obsessive compulsive states*.

9. *Epilepsy*.

10. *Mental defect*.

11. *Schizophrenic psychoses*.

12. *Affective psychoses*.

13. *Tics* which cannot be placed in any of the above categories.

14. *Stammer* in cases which cannot be listed under any of the above categories.

#### SYMPTOMS TWO YEARS AFTER TREATMENT

The incidence and ultimate fate of individual symptoms of these types were studied in a series of

80 cases which were followed up after a period of two years by personal visits from the social worker. It was found that improvement or actual recovery was the rule for all groups, not excluding even the mentally defective. In nearly all individual symptoms failure to improve was very exceptional. This is not to be attributed merely to maturation, as might be expected in the mental defectives for example, but to many other factors of which treatment is sometimes one. The total number of patients is much too small for reliable statistical treatment of syndromes or individual symptoms, but they serve to strengthen the general impression that the following statements are true.

*Scholastic difficulties* other than those due to defect of general intelligence, such as backwardness from difficulties over a special subject like arithmetic, or to faulty methods of teaching, or to some source of unhappiness at school, commonly disappear when accurately diagnosed and adequately treated, especially by coaching. This is perhaps the most favourable of the individual groups of symptoms and the results here alone would justify the assertion that a clinic for child guidance is an essential part of any educational system.

*Behaviour disorders* also commonly have a favourable outcome. Of 64 instances of symptoms falling under this head 31 were recorded as well two years later, 26 as improved or much improved, and only 7 as in statu quo. Of this type of symptom wandering and truancy are in our experience probably the most difficult to abolish, at least in a city population of the poorer class and where a residential school régime cannot be provided. Stealing in a similar population can be stopped in a considerable proportion of cases but not in all. Provision of suitable residential arrangements, especially in an atmosphere where much attention was paid to character training, would in our opinion considerably increase the effectiveness of treatment. Cases of behaviour disorder, so grave as to suggest a diagnosis of moral imbecility in an older terminology, commonly clear up surprisingly well if properly handled. Naturally the prognosis of an item of behaviour must be considered both in relation to personality and to environment. If wandering or a peculiarly persistent refusal to go to school are the expressions of an early schizophrenic psychosis the prognosis is of course that of the latter. The more the behaviour can be shown to be the outcome of environmental factors, including in that term the play of affection or the reverse around the child, the better the prognosis.

*Personality traits* are by definition more difficult to modify than difficulties of behaviour. These are both more habitual and less tangible than the latter. A-social characteristics are among the most frequent and the most difficult to influence. Such characteristics are so common in the anamnesis of adult psychoneurotics and psychotics that the reflection is obvious that a successful attack in childhood on them might do something to limit the incidence of adult breakdowns. Timidity and its variants are on the other hand among the most readily influenced, and so are temper tantrums. Obstinacy or stubbornness occupies a middle position in probable outcome and our impression is that negativistic traits rank next to a-social ones in their value as warning signals of a subsequent adolescent or adult breakdown. Persistent cruelty in spite of environmental manipulation is also a bad omen.

Of the *vegetative disturbances* those of sleep are commonly much improved or cured. Sleep-walking

is in our belief not by any means always psychologically determined. It may be due to physiological instability of the nervous system and occasionally perhaps to epilepsy. Disorders in this group commonly subside when the general health is satisfactory, but in addition glucose at bedtime, bromide sometimes, and occasionally Luminal, are effective. Enuresis is a problem in itself and is included in this group only when it has existed since infancy and when it seems uninfluenced to any extent by psychological factors or when none of these are discoverable. Nevertheless it has, on the whole, ultimately a favourable prognosis whatever category it belongs to. The "physiological" type, as we call it, according to the definition we have given, commonly clears up about puberty; and comparatively few cases of whatever origin persist into late adolescence. We have seen every sort of remedy cure enuresis and in individual cases have seen everything fail.

Our experience of the *psychoneurotic disturbances* of childhood is on the whole a favourable one. We refer of course to clinical pictures which are dominated by psychoneurotic symptoms and not so much to minor childish phobias such as fears of the dark. We have been surprised to find how readily psychoneurotic conditions in children subside on a mere change of environment: how they may stay away so long as the environment remains suitable; and how, if properly handled, they need not necessarily relapse on the return to the family. This is of theoretical significance when we consider the Freudian theories of the origin of such conditions. It is our impression that such symptoms tend to disappear also with a non-interpretative play technique.

*Psychoses*, although rare in young children, are occasionally met with in them and may be of the affective type. For schizophrenic conditions occurring in young children the outlook is usually although not invariably poor. It is however worth emphasizing that for schizophrenic psychoses occurring in adolescence the proportion of recoveries is much higher than is usually realised. For example, in 72 cases occurring between 14-17 Ssucharewa (1932) recorded that 72 per cent. had more or less complete remissions, and of 27 cases followed up five years later 52 per cent. had no subsequent attacks, while the remainder of the 27 cases had further attacks with ultimate complete deterioration. Among the manic-depressive psychotics recovery probably takes place in the majority, though they remain liable to subsequent attacks. Of four young psychotic children seen as out-patients at Guy's Hospital in the last few years, one of an affective and two of a schizophrenic type have deteriorated, and another (schizophrenic) has made a great improvement.

We have placed *stammer* in a special category because we are not satisfied that it can properly be regarded as hysterical in a high proportion of cases. Such data as have come to our knowledge suggest that about two-thirds of cases in childhood recover by late adolescence, but in those cases in which stammering persists until 17 or 18 it is apt not to be cured by any methods whatsoever, although it may be considerably improved. Nevertheless the fact that stammering in middle life is rare suggests that here again a spontaneous factor is at work for ultimate recovery.

#### CONCLUSION

The factors that influence recovery or improvement are many; and it is difficult to ascertain with any degree of precision to what factor recovery is to be attributed; but a list would include: talks with a

psychiatrist and talks with a social worker (the talks may be with the parents as well as with the child); various kinds of environmental manipulation, such as foster homes, residential schools, change of school, change of work, going to work for the first time, going up to senior school, removal of the home to another district; medical measures of the more ordinary kind, such as medicine and rest; and finally, the mere lapse of time which implies maturation or perhaps emancipation from earlier problems.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. J. E. Clark to *Malabar* for Bermuda Dockyard.

Surg. Lt.-Comdrs. J. A. Cusack and V. F. Walsh to rank of Surg. Comdr.

Surg. Lt.-Comdr. A. L. Moorby to *Pembroke* for R.N.B.  
Surg. Lt. L. G. Yendoll to *Drake* for R.N.B.

S. J. Atkinson, H. B. Watson, and E. C. Janet, as Surg. Lts. (D), for short service and appointed to *Victory* for R.N. Hospital, Haslar.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. R. R. B. Roberts to *Drake* for R.N.B.

Surg. Lt.-Comdr. (D) E. D. Collins to *Victory* for R.N.B.  
Surg. Lt. R. D. Jenkins to *Ramillies*.

### ROYAL ARMY MEDICAL CORPS

Short Service Commissions: The undermentioned Lts. to be Capts.: P. L. E. Wood, P. R. Wheatley, A. C. Cox, J. J. Groome, J. S. Kelleher, C. Ryan, W. B. Hamilton, D. S. Cochran, T. P. O'Brien, M. A. Flaherty, E. J. Pryn, and J. P. Weir.

The undermentioned Lts. (on prob.) (vide THE LANCET, May 9th, 1936) are sec'd.: S. E. Osborne, V. Bennett, G. N. Barker, and R. A. Hoey.

### ARMY DENTAL CORPS

Capt. W. B. Purnell to be Maj.

Short Service Commissions: T. A. Smitham to be Lt. (on prob.).

### TERRITORIAL ARMY

Cpts. N. H. Watson and N. Harkness resign their commissions.

Lt. R. D. Forsyth to be Capt.

### ROYAL AIR FORCE

Wing Comdr. C. P. Barber to No. 6 Flying Training School, Netheravon, for duty as Medical Officer.

F. L. Whitehead is granted a short service commission as a Flying Officer.

*Dental Branch*.—Flying Offrs. I. St. C. Alderdice to No. 1 School of Technical Training (Apprentices), Halton; O. F. Brown, J. H. G. Fensom, R. A. Pepper to Home Aircraft Depot, Henlow; S. Hill to R.A.F. Depot, Uxbridge; and W. A. H. Smith to R.A.F. Station, Manston.

### RESERVE OF AIR FORCE OFFICERS

*Special Reserve*.—A. C. Fraser is granted a commission as Flying Officer.

### INDIAN MEDICAL SERVICE

The names of the undermentioned have been brought to notice by the Commander-in-Chief in India, for distinguished services rendered in connexion with the Mohmand operations N.W. Frontier August to October, 1935: Lt.-Col. H. B. Scott, O.B.E., Capt. F. J. Doherty, D.S.O., Lt.-Col. R. K. Mallam, R.A.M.C., Maj. C. A. Slaughter, R.A.M.C., and Maj. M. P. Power, O.B.E., M.C., R.A.M.C.

Lt. J. M. F. Byrnes relinquishes his prob. appt.

## SPECIAL ARTICLES

## RELATIVE VALUE OF RAW AND HEATED MILK IN NUTRITION

BY ELFREIDA C. V. MATTICK, M.Sc., Ph.D. Bristol  
AND

J. GOLDING, D.S.O., F.I.C.

(From the National Institute for Research in Dairying,  
the University, Reading)

In a previous paper on the relative value of raw and heated milk in nutrition,<sup>1</sup> long-continued feeding experiments with rats in which different types of milk were used was described. It was shown that in the first experiment while a fourth generation receiving raw milk were weaned successfully, only dead pups were born to the second generation on "fresh" sterilised milk, and no second generation were weaned on "kept" sterilised milk.

In that paper we said: "It is proposed to keep some members of this fourth generation in an endeavour to determine the number of successive generations which can be raised on this particular diet." We now give the history of these subsequent generations.

## RESULTS OF THE INVESTIGATION

The technique used and the source of the milk remained unchanged. All the results given here are from a first and single mating only, in each generation. Except in the early stages when suitable weights were considered, mating was entirely "random" within the possibilities of cross-mating. If it had been possible to keep all the rats which were weaned and to carry out successive matings it is possible that our efforts would have been more successful; on several occasions families were weaned from later but not from a first mating. It must be remembered that the diet was at no time considered to be ideal.

The number of pups born and weaned in successive generations are shown in Table I. For the sake of

comparison the results of "fresh" and "kept" sterilised milk are included.

The results with "sterilised" milk, both "fresh" and "kept," have been discussed<sup>1</sup> and hardly need further comment. Those with raw milk present various interesting features. The does of the first, second, and third generations all produced litters at a first mating; in the later generations one or more in each case failed to produce litters. These failures in production were not, however, increasingly numerous in successive generations. In the seventh generation, one doe of four did not become pregnant, but the remaining three produced nineteen pups (litters of four, seven, and eight). None of these were weaned, for the does failed to lactate. It is this failure to lactate which seems to be the limiting factor in this type of experiment, and it is noticeable that this is present throughout the experiment and may be due to inadequacy of the diet or to some unknown factor which is found to affect does in many similar experiments.

A comparison of the rate of growth and average weight at similar age of the members of successive generations is shown in Figs. 1 and 2 and in Table II.

From Table II. it is seen that at 120 days the average weights of the first generations (litter brothers and sisters) on each type of milk are somewhat similar; the "kept" sterilised bucks and the "fresh" sterilised does having respectively the highest and lowest values. No second generation was weaned on "kept" sterilised milk while the second on "fresh" sterilised were quite abnormally small and light (photograph given in earlier paper).<sup>1</sup> The numbers in these groups are so small that the results might quite reasonably be regarded as insignificant except for the fact that the original rats in each group were litter brothers and sisters selected from two litters only. No further comparison between groups can be made. A quite definite falling off in weight of animals of the same age on raw milk is shown in subsequent generations compared with the first and second, but again it is interesting to note that this is not progressive, the average weight of the fourth to the seventh generations of bucks being con-

siderably higher and of the does either identical or slightly better than those of the third generation.

These results are clearly indicated in Figs. 1 and 2, which show the average growth curves for bucks and does respectively in each successive generation until the time of mating.

The significance of these differences between the average weight of the animals in the different groups and in different generations of the same group was found by comparing each with twice its standard error.\* When a difference is greater than twice its standard error, we may regard the measurements as evidence of a real distinction between the two quantities whose difference is in question.

In groups where the numbers are less than ten, a correction established by "Student,"<sup>2</sup> but in the form adopted by Jeffreys<sup>3</sup> was introduced. This makes the comparisons considerably more stringent than they would otherwise be. The results of the statistical calculations show that the average weights of bucks and does in the three groups receiving raw, "fresh" sterilised, and "kept" sterilised milk were not significantly different in the first generation.

Differences between the second generation does on raw and "fresh" sterilised milk, and the first

from the tails and a hæmocytometer was used. The hæmogoblin was estimated by the acid hæmatin method using a Klett colorimeter. The blood of rats aged 110-117 days which had been kept on the

A.w. ♂ ♀ = average weight in grammes of bucks and does respectively.

and second generation bucks and does on "fresh" sterilised milk are very significant. There is no significant difference between the average weights of successive generations from the third to the seventh in either bucks or does on raw milk.

The reason for the falling off in weight in the third generation and subsequent stabilising is not known, but recorded data show that it is not apparently due to inbreeding, age of rats, or time of year at mating. It may be significant that the second generation rats were bred from does whose parents had been raised on a stock diet, and it is possible that the benefits of this original stock diet were not lost until after the second generation, while from the third onward the rats had become accustomed to this insufficient diet of biscuit and milk. Failures in lactation were found in the first generation.

**Red cells and hæmogoblin blood content.**—Towards the end of this experiment some estimations of the number of red cells and hæmogoblin content of the blood of stock (11 bucks) and experimental (5 bucks, 5 does) rats were made. The samples were taken

milk and biscuit diet showed a statistically significant higher number of red blood-cells, and lower hæmogoblin content, indicating a tendency to anæmia which, however, disappeared with increasing age. On the other hand, the animals on stock diet showed lower values of statistical significance—of both red cells and hæmogoblin as they became older. At 358-386 days there were no statistically significant differences in either red cells or hæmogoblin in the blood of the experimental and stock rats examined.

**Bone analysis.**—Analyses of the leg bones of six rats of the second generation were carried out. These were one buck and two does from the raw and two bucks and one doe from the sterilised milk group. The age of all the rats was between 473 and 486 days. Statistical calculation of the results showed that the ash and calcium contents of the

FIG. 2.—Rate of growth in successive generations. First experiment. All does.

bones of the raw milk fed rats were slightly but definitely greater than in those receiving sterilised milk. The differences in the phosphorus content were not significant.

Results of the analyses of the leg bones of a seventh generation doe (aged 516 days) showed that after four years' feeding of successive generations on a diet of raw milk and flour and water biscuit there was no diminution in the ash, calcium, and phosphorus content of the bones.

**Condition of teeth.**—It is interesting to note that at an age of 477 and 516 days respectively, no dental lesions could be found in a seventh generation buck

\* The standard error of the difference between two quantities is the square root of the sum of the squares of individual standard errors of the two quantities.

and only doubtful earliest signs of carious lesions in a doe of the seventh generation on raw milk. Examination of the teeth of these rats was very kindly made for us by Dr. Evelyn Sprawson of the London Hospital dental school.

#### CONCLUSIONS

(1) Rats from the same litters placed at weaning on diets of biscuit made from flour and water only and of (a) raw, (b) freshly sterilised, and (c) kept sterilised milk, show marked differences during a long-continued experiment.

(2) No second generation was weaned from the group receiving "kept" sterilised milk. No third generation was weaned from the group receiving "fresh" sterilised milk. Second, third, fourth, fifth, sixth, and seventh generations were weaned from first matings only of successive generations in the raw milk group.

(3) Although the rats originally placed on these diets at weaning from stock (called first generation) showed no significant differences in average weight at time of mating, the second generation does on fresh sterilised milk were significantly lower in weight than the original rats receiving either raw or sterilised milk.

(4) After the third generation no significant differences in the average weights of either bucks or does were found in successive generations on raw milk.

(5) The possibility of anæmia in the younger rats on the experimental diet is shown by a consideration of the statistical significance of the differences in the average red cell count and hæmoglobin content of such rats compared with those on a stock diet of similar age—such differences are no longer significant in the case of older rats.

(6) Analysis of bones of rats of the second generation on raw and fresh sterilised milk show that the bones of the former contain slightly more ash and calcium than those in the latter group.

(7) No dental lesions could be found in a buck and only doubtful signs in the teeth of one doe of the seventh generation on raw milk.

## ROYAL SOCIETY OF MEDICINE

THE biennial dinner of the society was held on May 9th, at the May Fair Hotel, London, when about 180 fellows and guests sat down. The president, Dr. Robert Hutchison, was in the chair, and after the loyal toasts "The Royal Society of Medicine" was proposed by the Minister of Health, Sir KINGSLEY WOOD, who remarked that he was to enjoy a night out as the society had, he understood, nothing to do with medical politics. It was born, he was told, in a tavern in 1805 under the name of the Medical and Chirurgical Society for the purpose of conversation on professional subjects, for the reception of communications, and for the formation of a library. Since that time its numbers had increased until to-day it was housed in a magnificent building in Wimpole-street with a Royal Charter, a roll of over 5000 fellows, and twenty-four sections dealing with all branches of medicine. The printed "Proceedings" acted as the ambassador of the society all over the

world to report advances and progress in medical knowledge. It was, he said, one of the aims of the Ministry of Health to secure unity and coöperation in health and medical administration, to prevent overlapping and waste of effort, and so to secure the exertion of maximum effect. Between 1846 and 1902 many other medical societies were formed for the advancement of special studies, all doing excellent work within their own spheres. Owing to rivalry and lack of coördination, however, progress was not as marked as it should have been and it was a happy thing when the amalgamation of seventeen of these societies ensured the success of what became the Royal Society of Medicine. He congratulated the society on its financial stability and increasing membership, due in large measure to the loyal service of the late Sir John MacAlister and of Mr. Geoffrey Edwards. The Ministry of Health was primarily concerned with the prevention of disease and it was becoming more difficult to draw the line where prevention ended and treatment began. This society provided the Minister with standards on which to model and keep bright his work. He coupled with the toast the name of Dr. Robert Hutchison, equally distinguished as physician, medical historian, wit, and expert on nutrition.

Dr. ROBERT HUTCHISON, in reply, spoke of the loss sustained by the society in the death of their patron, King George V. They hoped that Royal patronage would again be extended to them by King Edward. In thanking the Minister of Health for his presence he spoke of the pleasure felt by the society of putting before the Ministry the knowledge and experience of the many great men contained in its ranks, for the society knew no politics, medical or other. Their only regret was that they were not consulted oftener. The society, he went on, had three functions to perform: it had to supply the apparatus of knowledge; to provide for the interchange and diffusion of knowledge; and to promote good fellowship amongst its members and the profession at large. It was his belief that these three functions were efficiently fulfilled. The library, he was told, ranked fourth among the great medical libraries of the world; its maintenance was regarded as a first charge on income. Men in the remoter parts of the Empire had said how helpful the library service was to them. The sectional meetings were well attended, but he felt himself that the discussions were too polite; a little unparliamentary language at times would be a useful tonic. A tavern was, he thought, a good place to be born in, for it at least ensured that the society was imbued with the spirit of sociability. There was no reason for a learned society to be solemn or pompous in its lighter moments and under the inspiration of the present secretary the society's house was becoming more of a club and their receptions more frivolous—e.g., a recent study of the embryology of Mickey Mouse. Financially they were doing well; the budget had been balanced with a substantial surplus. They had done that off their own bats, they had robbed no hen-roosts. He felt it a great honour to be president of the society, and a great responsibility, although fortunately that responsibility was shared, and he would be wanting in gratitude if he did not acknowledge the constant help received from the honorary officers and from the permanent staff.

The toast of "The Guests" was proposed by Mr. ERIC PEARCE GOULD, who paid a very pretty compliment to their rôle at a medical dinner in pandering to doctors' natural delight in gluttony. When we

dine alone in our own homes, he said, a simple meal is all we allow ourselves; but once introduce a guest to the table and up go the calories and out go the vitamins. He extended a warm welcome to several guests, little known to fellows, yet who contributed largely to the stability of the society: Sir Alfred Lewis, financial adviser, Mr. J. H. C. Burton, bank manager, Mr. J. W. Pepper, solicitor, and Mr. G. G. Turner, representing the auditors. He coupled with the toast the name of Mr. Guedalla who had for many years sublimated his ego in a series of fascinating historical studies. Medical literature could be made more palatable and more easily digested if something of his grace and wit were interwoven with fact and figure.

Mr. PHILIP GUEDALLA thanked the society for its lavish entertainment and for its continued interest in their health. His own presence there was due, he supposed, to the society's determination that there should be one specimen of the patient class, in the same spirit in which the ancients enlivened themselves by the presence of one mummy. Patients had feelings too, feelings of gratitude, though not always feelings of respect, "for you cannot do much about a common cold; but it is to you that we go when we are in real trouble—I do not know why." In final reply to the toast, Mr. Guedalla said: I would say that your calling and my calling both depend on the free use of their minds by free men and women, which is something which has disappeared from the more backward parts of the world. If we did not remember it no one would.

## SCOTLAND

(FROM OUR OWN CORRESPONDENT)

### SURGEONS IN EDINBURGH

THE Association of Surgeons, which held a successful meeting in Edinburgh last week, last met in Edinburgh 15 years ago when Sir Harold Stiles was president. On the present occasion Sir David Wilkie presided and there were over two hundred surgeons present. On the mornings of Thursday and Friday, discussions were held on the treatment of fracture of the neck of the femur, and on the treatment of bleeding peptic ulcer. Operations were demonstrated in the afternoons, and an excellent pathological demonstration was arranged. On Friday evening the members dined together in the upper library hall of the University. On Saturday morning several short communications were given, mainly on experimental studies. The weather was good and many of the members found time to play golf.

### CHRONIC PROGRESSIVE HYDROCEPHALUS

At a meeting of the Medico-Chirurgical Society of Edinburgh held last week, Mr. N. M. Dott and Dr. Ernst Levin presented a paper on chronic progressive hydrocephalus. They included in this group of cases those in which there is progressive and excessive accumulation of cerebro-spinal fluid with increasing intracranial pressure which are caused by an inflammatory process. They have experience of 60 of these cases and find that their incidence as compared with cases of brain tumour is in the proportion of one to ten. They emphasised the importance of these cases, and find that the result of surgical treatment is usually good. They classified the cases on an anatomical basis according to the situation at which the circulation of the cerebro-spinal fluid was princi-

pally interfered with. They divided them into three main groups: (a) chronic diffuse meningitis, (b) chronic adhesive meningitis, and (c) chronic plastic ependymitis. The first group is sometimes termed chronic serous meningitis. There are no visible adhesions and the obstruction is over the convex surface of the hemispheres and interferes with the absorption of the cerebro-spinal fluid into the blood. Diagnosis is made by ventriculography which shows no distension of the ventricles but great distension of the subarachnoid space over the hemispheres. Bitemporal decompression usually gives good results in these cases. The second group of adhesive meningitis may be subdivided also on an anatomical basis, according to the site of the obstruction which may be in the sulci of the brain or in the cisterns. An encysted form of this disease may produce symptoms and signs identical with those of brain tumour, and such cases can be cured by removing the outer wall of the cyst. The type of case in which the peri-pontine adhesions occur causes huge distension of the cisterna magna and is the most unsatisfactory form to treat by operation. In the perimedullary type the adhesions prevent the cerebro-spinal fluid from escaping freely from the fourth ventricle and this type can usually be well relieved by operation. Cases of plastic ependymitis are rare, but may cause narrowing of parts of the ventricular system. Obstruction of the aqueduct of Sylvius may be caused in this way and treatment may be attempted by draining the third ventricle into the chiasmatal cistern. When one foramen of Monro is obstructed in this way the condition can be successfully relieved by making an opening in the septum lucidum. Mr. Dott has operated on two such cases of unilateral hydrocephalus. The results obtained from the whole group show about 70 per cent. cured, 10 per cent. recovered with more or less disability, 5 per cent. operative deaths, and 15 per cent. of the cases have subsequently died from progression of the disease.

### THE LATE DR. JAMES SWANSON

The death occurred on April 27th, in a nursing-home in Glasgow, of Dr. James Swanson. Dr. Swanson three years ago was knocked down by a motor-car which mounted the pavement, and he had never fully recovered from the serious injuries which he then received. He had been connected with medical education in Glasgow for nearly half a century. He graduated in arts at Glasgow University in 1881, and at first was a student of divinity, but after taking some instruction in medicine with a view to foreign mission work, he became so much attracted to medicine that he decided to qualify for that profession. He graduated M.B., C.M. in 1890, and obtained the fellowship of the Royal Faculty of Physicians and Surgeons of Glasgow in 1896. In his early days he conducted tutorial classes for medical students, and later was appointed professor of biology at St. Mungo's College, Glasgow, a position which he held for many years. He was a lecturer in botany at Glasgow University, and was the author of several books on botany. He was at one time an officer in the Territorials, and the company he commanded in the H.L.I. won the Ambulance Challenge Shield in London, and held it for several years. Dr. Swanson, who was himself a good horseman, was keenly interested in athletics of all kinds, and was president of the Glasgow Health Culture Society. He is survived by his wife, and a son and daughter. His son, Dr. George Swanson, is on the surgical staff of the Glasgow Royal Infirmary.

## PARIS

(FROM OUR OWN CORRESPONDENT)

## QUIS CUSTODIET IPSOS CUSTODES ?

The council of the Confédération des Syndicats Médicaux Français has recently issued a circular addressed to the heads of faculties of medicine and of scientific medical associations. It is pointed out in this circular that many and lively complaints have been made to the council on account of the repeated appearance in lay publications of scientific articles calculated to be interpreted as personal advertisements of their authors. No one would object, the circular proceeds, if the contributors to these freely illustrated publications were to confine their literary activities to always needed advice about prophylaxis and hygiene. The matter is quite different in connexion with articles dealing with treatment and showing temperature curves and so forth. The public who read such articles may have a keen appetite for them, but are unqualified to be discriminating in their judgment, and are apt to assume that the advice given is necessarily the best even though it may not coincide with that given by a general practitioner in charge of a case. "Further, allow us, with all the deference and respect we owe our masters, to point out that great prudence should be exercised in collaboration of this kind, when one has the honour to preside over the scientific and moral education of students, and to be, on many occasions, the valued councillors of general practitioners." It is to be hoped that the leaders of the medical profession, who have incurred this reprimand from the rank and file, will accept it in a contrite spirit.

## IS BACTERIOLOGICAL WARFARE POSSIBLE ?

The *Sicèle Médical* for April 1st gives prominence to a paper, published in Morocco, by Major Velu, bacteriologist and head of the Army Veterinary Service in Morocco. As well as being a distinguished bacteriologist and veterinary surgeon, Major Velu is a potential author of thrillers. The picture he paints of the next great war is credible as well as lurid. A few weeks before the outbreak of hostilities, which begin suddenly and without a warning of particularly strained political international relations, the enemy's agents create numerous centres of cattle plague in the country. The outbreak of this disease is followed by that of psittacosis, introduced by the surreptitious importation of infected parrots. Artificially introduced dysentery and typhoid fever follow suit. Then there is human plague, tularæmia, &c. When peace comes to be signed and the casualties are totted up, it is found that those due to artificially induced infections are numerically much inferior to those due to wounds and chemical warfare; for it will be established that the artificially induced infections sooner or later petered out of themselves. But this does not mean that bacteriological warfare is an ineffective weapon. Far from it. Major Velu anticipates as a reaction to bacterial warfare a state of confusion and panic dramatically destructive of its victims' morale. He pictures veterinary surgeons being called back from the front to attend to alleged outbreaks of disease in the interior, and the Pasteur Institute frantically switching off from one infectious disease to another as each outbreak in turn makes new demands for large supplies of serums and vaccines. "Certainly, bacteriological warfare is possible. Therefore it will take place."

## THE LITIGIOUS PATIENT

A recent lawsuit in Paris has centred about the Aschheim-Zondek pregnancy reaction. The plaintiff, a Madame Lévy, consulted in 1931 a medical practitioner who diagnosed fibroids of the uterus. A surgeon, Dr. de Martel, undertook to operate on her on Nov. 24th of that year. Laparotomy having been performed, he did not proceed to amputation of the uterus, for its appearance and consistency raised doubts in his mind as to the possibility of pregnancy. In January, 1932, the Aschheim-Zondek reaction was tested for the first time and proved to be negative. Seventeen months after the first laparotomy, Madame Lévy found herself again on the operating table, and this time the operator removed her tumour. This operation was perfectly successful. But Madame Lévy felt that it would have been superfluous had the first operator not made the mistake of suspecting pregnancy. He ought, she was convinced, to have made use of the Aschheim-Zondek reaction and acted according to its findings. The court thought otherwise, holding that, at the end of 1931, the reliability of this reaction had not yet been statistically and irrefutably established. Costs were given against Madame Lévy whose loss of this suit should have an inhibitory effect on other potential litigants.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

## THE PROBLEM OF TUBERCULOSIS

In the recent debate in the Dáil on the estimates of the Minister for Local Government and Public Health, attention was drawn by some deputies to the lack of progress in recent years in dealing with tuberculosis. In his reply the Minister gave information as to certain discussions which have been taking place between the officers of his Department and the Hospitals Commission on the treatment of tuberculosis. He only claimed to give a rough outline of what was in mind, and stated that plans had not been worked out in detail. He added that the present announcement might be useful from the point of view of eliciting criticism. From this point of view it might have been more useful if he had made the statement at the opening of the debate instead of at the close. The following are the main points of the plan under discussion: A person who was suspected, or suspected himself, of having tuberculous disease should visit a central or branch tuberculosis dispensary. After investigation the medical officer should classify the patient as (a) early or moderately advanced pulmonary tuberculosis capable of cure or improvement; (b) surgical tuberculosis of similar class; (c) observation case; (d) advanced or chronic case for which no improvement could be expected; (e) non-tuberculous. Cases classified as (a) or (c) would be referred to a chest hospital for thorough investigation and observation, and for surgical treatment in suitable cases. Patients would subsequently be drafted either to a central sanatorium where modern treatment would be available, or to a local tuberculosis institution for advanced and chronic cases. Cases requiring major surgical operation would be transferred as occasion arose to the chest hospital. Class (b) would be mainly dealt with at an orthopædic centre, which would be associated with an orthopædic school or

instructional centre. Minor cases might be dealt with at a county hospital. The present sanatoriums would provide accommodation for advanced and chronic cases. The units required for the scheme would be: (1) for each county and other district a central and branch dispensaries; (2) a central chest hospital in Dublin, and a wing or block in regional hospitals so located as to serve groups of counties; (3) central sanatoriums for groups of counties, equipped so as to provide the most modern and efficient treatment; (4) a central orthopædic centre or group of coördinated institutions to deal with surgical cases; (5) hospitals for advanced cases.

It is satisfactory that the Department is considering the problem in a broad way. The Minister suggested that to carry out the scheme legislation will probably be necessary. This will no doubt give the profession time to consider the matter and to offer what helpful criticism it finds proper. Care must be taken that tuberculous patients are not so exclusively segregated in special institutions as to interfere with medical education.

## WOODHALL SPA

### CONFERENCE OF THE BRITISH HEALTH RESORTS ASSOCIATION

"AN Englishman's morality is bounded on one side by the English Channel." This was quoted at the conference of the British Health Resorts Association held at Woodhall Spa on May 8th-10th. The speaker, Sir WALTER LANGDON-BROWN, said that in one particular the Englishman was persistently unmoral, for he still preferred to cross the water to visit his health resorts. The present time, however, is an opportune one, on account of the continent's unrest, for the British resorts once more to present their claims to the public.

Woodhall Spa thirty years ago enjoyed a certain reputation as a gynæcological spa, but since the late war it has sunk into comparative obscurity. Through the generosity and inspiration of Sir Archibald and Lady Weigall, the spa has been developed and the conference marked its recognition once again as a competent health resort. The waters are obtained from a coal shaft sunk at the beginning of the last century, and a new bath establishment was opened last year by Princess Marie Louise. The Weigall Clinic is equipped with the latest electrical apparatus, which, with the general regimen, the packs of local fango, and the social and natural amenities, has brought the spa into a position rivalling that of the better known but less accessible continental resorts.

The delegates to the conference were received by Sir ARCHIBALD WEIGALL, his daughter, the Viscountess CURZON, and the local authorities. At the first session, with Mr. WILLOUGHBY SMITH, in the chair, the subject was

#### The Spa Treatment of Gynæcological Conditions

Dr. J. BRIGHT BANISTER (London), opening the discussion, said that the Victorian obstetric physician would often recommend treatment at various spas and several notable authorities had included a list of suitable resorts in their publications. The evolution of the surgical gynæcologist had led to these methods being considered old fashioned and most of the patients came to be regarded as fit subjects for the scalpel. Many well-known text-books to-day did not mention this form of therapy. In spite of

this surgical bias, however, there were still people who would not be operated upon, and even gynæcologists who disliked operating, so that spa methods had not died out; but most of those for whom it was recommended had been sent to Kreuznach or other continental centres. Woodhall Spa had always been closely associated with the treatment of certain gynæcological disorders and the British Health Resorts Association, which had done so much to make known the possibilities of our own spas, might therefore reasonably attempt to raise it to the high place to which it was entitled. Referring to the indications, Dr. Banister said that subinvolution following miscarriage or childbirth was a condition that could be very definitely relieved by a stay in the spa. The douches would relieve the local hyperæmia and congestion, and the absorption of inflammatory products, while the regular régime of spa life would also be helpful. It was, however, essential to investigate thoroughly every case of bleeding before assuming that congestion was the cause. Spa treatment might also be adopted in chronic and subacute pelvic inflammation. It was often surprising how functional recovery could take place after purely conservative methods of treatment in cases that at the outset seemed doomed to operation. Chronic cervicitis and endometritis might also benefit and good results might be obtained in certain cases of sterility. They had to remember, therefore, that spa treatment and all that it implied was a very wide therapeutic measure. With the wider outlook now adopted by students of gynæcology its usefulness should be more generally recognised and, as there was evidence that the waters of Woodhall were particularly suitable for the relief of pelvic inflammation, he hoped for a return of its old prosperity. Many might in the future bless this spa for giving relief from their suffering and a way of escape from a surgical operation.

Dr. LEONARD BOYS (Woodhall) said that the Woodhall Spa waters were hypertonic saline and contained in addition appreciable quantities of iodide and bromide, as well as a large amount of calcium; magnesium salts to the extent of grs. 44 to the gallon were also present. The waters had been used in the treatment of certain gynæcological conditions for many years, and it was Dr. C. J. Williams who had first used them according to the Kreuznach system with such favourable results as to arouse appreciative enthusiasm for this "cure" in the minds of many of the leading gynæcologists in London, Edinburgh, and the provinces. The treatment at Woodhall consisted of giving baths at a more or less neutral temperature for from 15-45 minutes and, at the same time, a vaginal douche of the waters at 104° F., which in successive baths was increased to 118° F. The douche might be strengthened by the addition of motherlye, the concentrated waters. Alternatively, the douche was given with the pelvis and lower abdomen surrounded by fango compresses made from the local deposits. The bath had a sedative effect on the nervous system and stimulated metabolism. It improved the circulation of the pelvis, stimulated the uterine muscle to contract, and hastened the absorption of inflammatory products and thickenings. The douches thoroughly cleansed the vagina and external os. Among the conditions successfully treated were pelvic cellulitis, salpingo-oöphoritis, subinvolution, leucorrhœa, menorrhagia, fibroids, sterility due to congestion, vaginitis, and the mild prolapse due to lack of tone of the pelvic organs and supports. Many a patient exhausted by hæmorrhage, perhaps toxic

from constipation owing to pressure in the lower bowel, could be prepared for later operation by a course of spa treatment. In those also for whom an operation might be a very grave risk the "cure" offered an alternative. Finally, Dr. Boys described cases of pelvic inflammation, subinvolution, and sterility that had benefited from a course at Woodhall.

Prof. BECKWITH WHITEHOUSE (Birmingham) discussed the general value of spa treatment in relation to female pelvic ailments and the special advantages offered by Woodhall Spa. He said that to the older school of gynaecologists the advantages of Woodhall Spa were well known, and that in those days spa treatment was accorded an important place in the therapeutics of female pelvic ailments. It was opportune that the experience of the past should not be lost in the flood of new methods and new remedies, which often had not had the advantage of extended trial. On the continent spas had occupied a very definite place in the therapeutic armamentarium for a number of years. There on their very doorstep they had available natural resources equal to anything that Europe could offer; and yet they as a profession were neglecting many of those opportunities. The activities of many organs, and certainly of the pelvic organs, were dependent upon the correct and balanced interrelation of various hormones. Excessive strain upon the sympathetic and parasympathetic nervous systems, from over-work, worry, or errors in diet found its reward in hormonal and metabolic disorders such as thyrotoxicosis, amenorrhœa, and what the American called vagotonia and sympathicotonia. The syndrome that Crile termed "New York disease" was by no means uncommon in this country and most gynaecologists were familiar with the patient with symptoms and signs of lack of nutrition, cold extremities, exaggerated knee-jerks, &c., who often came complaining of amenorrhœa, insomnia, or anæmia. This modern product—the result of post-war civilisation and the counterpart of the "chlorosis" of the Victorian epoch—was the very type that must derive benefit from the British spas. There was no necessity for her to go to the continent. Indeed, in many cases the excitement and life associated with the majority of continental resorts was the reverse of helpful. The waters of Woodhall were remarkable in that they contained two elements of special therapeutic value to the gynaecologist, iodine and bromine. Modern research had shown the importance of iodine in the female for the proper function of the thyroid gland, and for the normal activities of the sex organs. Woodhall, therefore, was par excellence the ideal spa for the successful treatment and convalescence of patients showing signs of endocrine imbalance, for amenorrhœa, and oligomenorrhœa associated with defective ovulation, for sterility and, during the early stages of pregnancy, for women who had a tendency to habitual abortion. He himself knew of women suffering from uterine fibroids, in whom for various reasons surgical treatment had been inadvisable, who had been sent to Woodhall with benefit. The constitutional effect of increased iodine intake was often only shown after prolonged treatment; it was therefore necessary to ensure a constant supply to the patient, but this could only be done by bottling and efficient distribution. He concluded with an appreciation of the medical centre that he regarded as *the* gynaecological spa of Great Britain.

Sir EWEN MACLEAN (Cardiff) thought that to describe spa treatment as a way of escape from surgery would create a misunderstanding that would

be fatal to the good opinion of the profession. The remote results of sepsis—a subject fully discussed at Melbourne last year—were, he considered, the most suitable for this type of therapy. Ten years ago these prevalent and persistent inflammatory conditions were operated upon and this often led to such serious complications as fæcal fistula or to permanent invalidism, and Arthur Curtis of Chicago was to be thanked for showing how these patients could benefit from ambulatory treatment. In the spa proper and intelligent supervision was necessary to note the progress and to guard against complications. Woodhall Spa could rejoice in its reputation for treating these conditions.

Dr. F. HOWARD HUMPHRIS (London) thought that it was radium emanation that led to the good results in the spa treatment of chronic pelvic pain and of sterility. He felt that the temptation for the public to choose continental resorts was very great because they were as a rule very well advertised and subsidised.

Dr. MURIEL KEYES (Harrogate) believed that gynaecology was slowly recovering from an attack of surgical fever and that conservative therapy was again coming into its own in this country and in America. Patients were still liable however to be classed as neurotic or doomed to operation. Because every means of continental treatment was now available in Great Britain she felt that the average woman's conscience would at last allow her to undergo a less expensive "cure" at home. She was sure that to remove sepsis before cervical operations a careful toilet such as that given in the spa was essential.

Dr. W. EDGEcombe (Harrogate) was disappointed in the present attitude of benevolent toleration; it was damning the spas with faint praise. The lack of conviction came from a lack of personal knowledge and there was a crying want for the confidence that had been accorded to the continental spas.

Mr. L. C. RIVETT (London) said he had been struck by the need for spreading the knowledge of spa treatment. He felt that increased hospital accommodation would do much; his own outpatient clinic had many that would be suitable subjects; records could be kept and results of the work published.

Dr. Boys replied that Woodhall Spa had 30 hospital beds and to demonstrate the effects of its treatment he would welcome patients from London.

Dr. F. A. BEARN (London) thought that to bottle spa water was damaging to a spa's reputation if it failed to repeat the effects of its source.

Dr. C. W. BUCKLEY (Buxton) thought it was the radio-active substances that lost their effect on bottling or evaporation, and though the habit of drinking more water was always good, the effects depended on the composition of the water.

In the afternoon session the subject of

#### Food at the Health Resort

was discussed. Lieut.-Colonel Sir ARCHIBALD WEIGALL was in the chair. He said that the attention given to the diet of animals in veterinary research was lacking in the study of human nutrition. In health resorts, he felt, the chief difficulty was to cater for both the healthy and the invalid at the same time and in the same establishment. He thought that a special self-contained clinic with the waters, subsidiary treatment, and facilities for special diets housed in a single building was essential.

Prof. E. C. DODDS (London) thought the important

indication for spa treatment was the need for a general toning up of health. Though it was usual, particularly at continental spas, to combine dietetic with physical treatment, and though the two forms of treatment might be complementary, they could never replace each other; in the treatment of obesity no amount of physical treatment with baths or electricity would reduce a patient's weight unless the diet was very carefully revised. This applied equally well to all conditions for which spa treatment was employed—to metabolic disorders such as gout, to glycosuria in its various forms and, possibly, rheumatoid arthritis also required careful control of food and drink. Treatment could be applied both to the bodily intake and to the output. The latter, however, was not successful because the hardest exercise used only a little of the energy provided by a large diet. The intake could only be decreased by relative starvation, but this need not be unpleasant. In the foreign spas an Englishman would submit to a diet that he would consider intolerable at home, and it was difficult to understand why medical advice should command more obedience when given in broken English. On the continent also the amusements and dietary of the whole spa were subservient to its specialty. It was able to provide attractive food with a low energy value and it insisted on a disciplined life. It was still necessary, he said, to educate the British public in this matter, for it was useless to have efficient spa treatment in the clinics when the attractive hotels tempted the patient to continue his evil habits. Treatment had also to be continued, to a lesser extent, on returning home. The weight of the human body could be reduced to any degree compatible with life by adjusting the intake of food to the output of energy. When this fundamental fact was grasped it stood to reason that at the spas there was a sure method of reducing peoples' weight, but they could not do it without an adequate attention to the diet. He sincerely hoped that the Association would devote its time and thought to this problem, as he was certain that it was one of fundamental importance to the British spas.

Prof. V. H. MOTTRAM (London) spoke as an educationist. Dietetics, he said, was a new subject in Great Britain that had only recently shown signs of coming into its own. He agreed with Stefansson, the Arctic explorer, when he said that there was no field of human endeavour in which prejudices and custom took the place of sound thinking and rational experiment so much as in dietetics. Prof. Mottram had found that visits to hotels had left him replete with too much and too attractive food. The problem was one of balance, for the present emphasis was on protein and fat to the exclusion of carbohydrate, which led to a deficiency of vitamin C. He agreed with Prof. Dodds that it was difficult to "slim" in an ordinary hotel to-day; to the diabetic a holiday became a torture and to the nephritic a danger. He thought a dietitian was essential to a health resort; in coöperation with the physician on the one hand and the cook on the other, she could translate prescriptions into an attractive but effective diet. It would probably be worth while to let the public in the health resorts know that the food they consumed had not only been cooked by a first-class chef but that it had received the benediction of a first-class dietitian.

Mr. MORTON CHANCE (Harrogate) spoke from the point of view of a hotel caterer. He said that he had noticed that the patient who most rigidly obeyed the physician's advice was the one who recovered the

soonest. In each British resort were to be found hotels that would pay strict attention to the prescribed diets. A spa hydro was not a place of gloom and misery; as a rule it was more comfortable and cheerful than the ordinary hotels.

Dr. H. H. SANGUINETTI (London) deplored the average practitioner's ignorance of dietetics. He thought that a few standard diets to suit the various diseases were necessary though commercially difficult.

Lady HONYWOOD said she had found that the visitors were never satisfied with the prescribed diet and were always ordering extra dishes. She thought that exercise was an essential adjunct.

Dr. E. V. WORTHINGTON (Llandrindod Wells) said that there were three ways of giving a diet. The first was the continental method of having a single standard diet in all the hotels; the second was to have, as at Harrogate, a few standard diets that could be prescribed; and the last was the prohibition of certain foods, leaving the patient to choose the rest. A good physician, however, should be able to prescribe a diet to suit individual needs. He thought that the chief difficulty was lack of coöperation in the hotels; it was essential that they should prohibit clandestine "extras" that had not been prescribed by the physician.

Dr. EDGECOMBE said that he found both a single universal diet and prescriptions for individual diets to be impracticable. At Harrogate there were six simple standard diets—high calorie (3-4000 C.); low calorie (less than 1200 C.); low protein and high vitamin; reduced carbohydrate, quantitative or qualitative; high fat; and lacto-vegetarian. To these diets additions could easily be made. He thought that the psychological effect of a prescription was very great and the scheme had been an unqualified success.

Sir ARCHIBALD WEIGALL said that the large "luxury" hotels that did not coöperate were those that attracted the wealthy patient who as a rule went abroad for treatment; the attractive food and the amusements of the healthy visitors proved too tempting. He was sure that it was bad to combine luxury and a strict diet in one place.

Dr. BUCKLEY spoke of the value of vitamin C, especially in treating rheumatism. Veterinary experiments had shown that degenerative changes such as osteo-arthritis were commonest in horses suffering from a vitamin-C deficiency. Over-eating added to the trouble by increasing the weight. The addition of plenty of raw fruit and vegetable to the hotel diet would be invaluable.

In reply to a question by Prof. Beckwith Whitehouse, Prof. MOTTRAM said that present researches were showing that canning and cooking did not destroy all the vitamin C. The addition of alkalis would of course destroy it rapidly.

Dr. J. W. MCNEE (London) said that he always asked five questions about a spa before recommending it. What were its general amenities? What was the standing of its physicians? What discipline was required of the patients? How carefully would the diet be controlled? What arrangements were there for special investigations and treatment? He was certain that the British spas ought to specialise more and that a single clinic should contain all that was needed. He thought that it was almost impossible to accommodate both sick and healthy in one place.

Sir WALTER LANGDON-BROWN (London) believed that the Englishman's liking for foreign resorts was due to the greater expense and the better discipline. He felt that the difficulty was not merely one of the

diet—some were born to be fat—but he agreed with the importance of having dietitians in a resort. They would be valuable in varying the diet prescribed by the physicians. He prophesied that trained dietitians would be attached to chemists' shops to interpret prescriptions in the same way as the pharmacist.

Mr. GODFREY MOWATT said that in travelling abroad he found that the British spas would extend their foreign clientele if the patients could find someone to advise them in their own language. A list of available medical linguists should be valuable in every resort. He thought that the choice of a resort was generally a matter of habit and custom that was very difficult to break.

Dr. A. R. NELIGAN said that at Droitwich a prescription was made for the diet of each patient, a typed copy of which was given to the hotel caterer. The scheme was ideal but difficult in practice. The average chronic rheumatic who visited the spa was middle aged and over-weight. A well-balanced modified diet was therefore given, with a note explaining the subject to the patient and with instructions for use in the kitchen.

Dr. S. MONCKTON COPEMAN (London) said that vegetables were very badly prepared in this country. The addition of sodium bicarbonate to preserve the colour destroyed vitamin C and it was not generally known that a little brown sugar was a harmless substitute that had the same cosmetic effect. Experiments by the Ministry of Health had shown the great value of watercress. It provided the vitamins in high concentration, it was cheap and pleasant, and it was grown under carefully supervised conditions. It had also the advantage that it had a low calorific value. Children receiving it had thrived in a way only equalled by the group that had milk added to the diet.

Sir JOHN ATKINS (London) said that he had found it very difficult to persuade patients not to go abroad for spa treatment; tradition was partly to blame, but they also felt that there was nothing good to be had at home and that the great change would be beneficial. He felt that there was a weak link in the prescription of diets—their interpretation by the hotel—and a trained dietitian would remove this. Patients returning from a foreign spa had a comprehensive dossier of their whole treatment, progress, and results, with which the occasional curt note from the British spa physician compared very unfavourably, especially in the patient's eyes. There ought therefore to be a closer relationship between the spa physician and the private practitioner.

### Hospitality

The delegates were entertained in the evening to a banquet in the Petwood Hotel, formerly the home of Sir Archibald Weigall, who presided. In proposing the health of the Association he said that though the English produced the most skilled artisans in the world, they had never been successful purveyors of health. Abroad the Briton would loaf and laugh, at home he could only work and worry. This country, however, was unrivalled in its possibilities and in the variety of its climate. He thought that the local authorities could do much by removing petty and irritating restrictions. Lord Meston, president of the Association, replied. He voiced the regrets of the guests at Lady Weigall's indisposition, caused in part by her energy and self-sacrifice in the interests of Woodhall. The Association was to inaugurate at the conference a visitation of expert delegates to all the recognised spas, in order to check and verify their information and to coördinate their function.

Sir Ewen Maclean proposed the toast of Woodhall Spa and said the neglect of British resorts was due to the unsound practice of the lay public who preferred patent medicines, which they swallowed with the blatant advertisements, to a simple but sound prescription. The spas should aim at pleasing the pit and the dress circle as well as the stalls and the boxes. Mr. G. B. Barton, chairman of the Woodhall Spa Advancement Association, replied. Dr. Leonard Boys proposed the health of the guests, giving a summary of the spa's history and vicissitudes, and the Rt. Rev. The Lord Bishop of Lincoln replied.

On the last morning of the conference the delegates made a tour of the Tennyson country.

## MEDICINE AND THE LAW

### Trade Marks for Chemical Preparations

THE medical profession has a strong interest in eliminating confusion from the names of chemical preparations. It is understood that a dispute has arisen over the application of Oxo Ltd. to register the word "Thyroxoid" as a trade mark in the medicinal class. Chemical manufacturers of thyroid preparations, including thyroxine, are said to be opposing the application. They will probably argue that, if "Thyroxoid" is to be used for a thyroid preparation, it is a descriptive word and therefore inadmissible for registration; on the other hand, if "Thyroxoid" is to be used as the name of some preparation unconnected with thyroid products, then it is misleading and deceptive. The applicants are understood to be already the proprietors of the word "Oxoid" as a trade mark: they now seek to prefix the syllable "Thyr-": it remains to be seen whether the existing right to two syllables will justify the addition of a third syllable in front of them.

Some of the decisions of the courts are difficult to follow. The law used to admit to registration "fancy words not in common use." In the Bovril case, decided in this connexion in 1896, there was much discussion of "obviously meaningless as applied to the article in question" and "obviously non-descriptive." Lindley, L. J., held that "Bovril" was not a descriptive word, notwithstanding the association of "bov-" and ox. In 1904 the Court of Appeal even held that "Tabloid" was not a descriptive word, in spite of doubts by Lord Justice Stirling: or rather it held that when the word "tabloid" was registered in 1884, it was a distinctive fancy word not in common use. One hardly envies the judges the task of deciding these conundrums. Does "Colleen," as a name for a stove, induce the belief that the stove is of Irish origin? Is "Egall" too near an existing registered trade mark "Egrol" as a name for custard powder? Does the word "Sandovy" deceive if used for goods not consisting of real sardines? Is "Nuvola" (a medicated food) too near to "Nujol" (a medicine)? These are some of the questions which have required judicial answer. Whatever the legal principle, doctors, being humanly prone to the use of abbreviations, may easily fall into error if the only difference between the names of two products is that one word ends in "-oid" and the other in "-ine." There is seldom in these disputes any suggestion of fraud. Section 11 of the 1905 Act says a trade mark is not to be registered "if calculated to deceive." Industrial firms go as far as they can to get themselves the most alluring trade names with the maximum permissible of attractive association. The courts have to say how far they can go.

## CORRESPONDENCE

## TUBERCULOUS CERVICAL GLANDS

*To the Editor of THE LANCET*

SIR,—It was with some surprise and disappointment that I read in your issue of April 25th (p. 946) Dr. Brian Thompson's universal condemnation of excision in the treatment of tuberculous cervical lymphadenitis. I have always felt that the formation of a sinus in this condition, in any but exceptional cases, should be considered as a failure in treatment; it has been my experience that excision in cases with localised disease, which has advanced to caseation or suppuration, is followed by highly satisfactory results, which can be termed cures. It is, however, essential at operation to excise completely all tuberculous tissue, often a tedious and meticulous procedure, which is, however, rewarded by the fact that there is neither sinus formation nor local recurrence—results which appear to have been only too common in the cases which Dr. Thompson has observed, and which have determined his rejection of this form of treatment.

I am, Sir, yours faithfully,

London, W., May 7th. VERNON C. THOMPSON.

## ENCEPHALITIS LETHARGICA AND THE LAW

*To the Editor of THE LANCET*

SIR,—Recently at the Leeds Assizes a man of the name of Turner, who, according to the evidence of the police surgeon, had a history of sleepy sickness, was sentenced to two years' hard labour for assaulting four small boys by caning them. He had previously twice been convicted of similar offences, and said in his evidence, "I know it is wrong but I cannot help it."

Some years ago I published in your columns the case of an ex-Service man who was sent first to prison and later, for a subsequent offence, to a criminal lunatic asylum for assault, and at his post-mortem examination, following suicide, a piece of shrapnel was found in his brain. Later I happened to be attending the Norwich Assizes when I was asked if I would give expert evidence in a case of a sexual offence. I did so—the case was one of fetishism—and after laying my views before the court, to which judge, jury, and bar listened with interested attention, the man was acquitted. Counsel assured me that if chance had not taken me into the court for another case the accused would certainly have been convicted.

Surely the time has come, and indeed is long overdue, when the law should be altered so that persons suffering from morbid mental conditions, the result of illness, accident, or heredity, should be treated as irresponsible mental cases rather than as responsible criminals—even though they may not have any obvious delusions.

The bench, the bar, solicitors, and juries are quite naturally ignorant of morbid psychology and it appears to be a grave miscarriage of justice, for which legislators rather than lawyers are responsible, that morbid mental states should be punishable by law. Judges in their proper disgust at the acts committed, and in ignorance of the irresponsibility of the unfortunate victim of brain damage, too often permit themselves to express opinions which to those who have medical knowledge appear to be not only unjust but vindictive. The medical history of every case that suggests the possibility of a mental kink

should be gone into most carefully and the accused should be given the benefit of the opinion of a medical expert, while the police surgeon's evidence, though doubtless given in all good faith, should not be accepted as final.

I have drawn the attention of the Home Secretary to Turner's case.

I am, Sir, yours faithfully,

Harley-street, W., May 10th. H. WANSEY BAYLY.

## TREATMENT OF MAMMARY ABSCESS

*To the Editor of THE LANCET*

SIR,—Reading in your issue of Feb. 22nd (p. 440) of Messrs. Battle and Bailey's dissatisfaction with the results of incision and drainage in mammary abscess, I should like to tell you something of my own experience. As a student I saw mammary abscess treated with incision; after pressing out the pus, we put in a tampon of vioform gauze, renewed every day until the wound healed. The treatment was very painful but the result was good. As a young practitioner I treated mammary abscess with incision, insertion of a tampon of gauze, saturated with Goulard's lotion or alcohol, covered with Billroth batist, the tampon being renewed every day. The treatment was painful but the result was good. Not content with this, I tried a stock vaccine known as Propidon, giving three injections of 5 c.cm. at an interval of two to three days. After each injection the woman has a rigor and the temperature rises to 104° F. Sometimes this drastic treatment leads to cure; but it may be necessary to open the abscess. More recently I have been in the habit of applying an ice bag for about five days while the patient rests in bed, followed, if this does not suffice, with local application of 10 per cent. iodine pot. iod. ointment and hot poulticing. When the presence of pus is certain I make an incision 3 cm. long, put in a pair of forceps and after pus is evacuated place in the cavity a tampon of gauze saturated with common cod-liver oil, covered with Billroth batist, leaving this for four days, when the woman is cured. During this period the temperature remains normal, there is no pain, sometimes a disagreeable odour—but that is no matter. The method is easy, safe, and quick. All my recent cases have done well.

I am, Sir, yours faithfully,

Nijmegen, April 28th. H. FEIKEMA.

## MENTAL SICKNESS AND CERTIFICATION

*To the Editor of THE LANCET*

SIR,—The account given in THE LANCET of May 9th of the new hostel to deal with mental sickness which is to be built in association with the Institute of Medical Psychology will be welcomed by all who are familiar with the pressing need for such facilities of treatment in London, and indeed throughout the country. At the same time it compels attention to the unsatisfactory state of the law in relation to mental patients, and of the difficult position in which the Board of Control is likely to be placed when such special hospitals are established.

As the law now stands, patients who are considered to be certifiably of unsound mind must not be kept for treatment except in a place licensed or approved by the Board of Control and subject to visitation by the Commissioners. This introduces

complications into the question of treatment such as the new hospital may wish to avoid, and brings into relief the old but increasingly important problem of the stigma of certification. It is the opinion of most doctors experienced in mental illnesses that a change in the law on this subject is urgently required. A great opportunity was lost in the Mental Treatment Act, 1930, and the present time would seem to be a very suitable occasion for a reconsideration of the legal aspect of this form of illness so that the law can be made helpful and not an obstruction in the treatment of these distressing cases.

I am, Sir, yours faithfully,

Wimpole-street, W., May 9th. FREDERICK DILLON.

**BLOOD COUNTS IN TUBERCULOSIS**

To the Editor of THE LANCET

SIR,—In view of the increasing interest that is being taken in blood counts in tuberculosis, I have carried out the following experiments. Blood was taken from a freely flowing stab wound of the ear in three cases, two tuberculous patients and one normal person. Blood films were prepared and stained by Jenner's method. The films were then sent to 11 competent authorities who were asked to do a differential count on each of the three slides (one from each case) sent to them. The results are tabulated below:—

SLIDE 1

Polymorphs.	S. Lymphs.	Monocytes.	Eosinophils.	Others.	Polymorphs.	S. Lymphs.	Monocytes.	Eosinophils.	Others.
53.3	22.3	23.3	1.1	0	62.0	29.0	4.5	4.0	0.5
43.0	29.5	25.0	3.0	0.5	61.0	28.0	9.0	2.0	0
32.0	12.0	40.0	1.0	0	72.0	15.0	10.0	2.0	1.0
64.0	25.5	5.0	4.5	1.0	60.0	27.0	9.0	4.0	0
67.0	20.4	6.5	4.5	1.3	65.0	20.0	9.0	5.0	1.0
62.0	19.0	14.0	5.0	0					

SLIDE 2

Polymorphs.	Lymphocytes.	Monocytes.	Eosinophils.	Others.	Polymorphs.	Lymphocytes.	Monocytes.	Eosinophils.	Others.
74.0	7.3	11.0	7.7	0	68.0	10.0	10.5	11.5	0
68.5	14.0	10.0	7.5	0	72.0	11.0	8.0	9.0	0
67.0	9.0	13.0	11.0	0					
76.5	10.0	6.5	7.0	0	68.0	19.0	4.0	9.0	0
59.0	13.0	12.6	15.3	0	70.0	9.5	12.5	7.0	1.0
69.0	4.0	16.0	11.0	0					

SLIDE 3

37.5	52.9	3.6	3.6	2.4	38.0	55.0	3.5	2.5	1.0
43.5	45.0	6.0	4.5	1.0	48.0	46.0	3.0	3.0	0
50.0	36.0	12.0	1.0	1.0					
48.5	47.0	2.0	1.5	1.0	51.0	43.0	3.0	3.0	0
48.4	45.6	3.0	2.6	0.4	30.5	65.0	2.0	1.5	1.0
45.0	38.0	15.0	2.0	0					

It was thought that the surprising variation in the counts might be due to—

- (1) The collection of the blood by stab puncture.
- (2) The fact that the counts were made on different films by each pathologist.

I therefore made a film from blood taken from one patient by venepuncture, and sent this one slide

round to the various hæmatologists and asked for a differential count again. The result was as follows:—

Polymorphs.	Lymphocytes.	Monocytes.	Eosinophils.	Others.	Polymorphs.	Lymphocytes.	Monocytes.	Eosinophils.	Others.
63.3	27.6	8.0	0.6	0.3	75.0	20.0	5.0	—	0.0
66.5	22.5	8.5	2.0	0.0	65.5	27.0	6.5	0.5	1.0
66.0	23.0	9.0	2.0	0.0	65.0	27.0	5.0	3.0	0.0
70.0	20.6	5.2	3.2	1.0	65.0	30.0	4.0	1.0	0.0
67.0	21.0	10.0	2.0	0.0					

It will be seen that reasonable uniformity was now obtained although there was still a greater variation than one would have thought possible.

The experiment seems to show that blood films made from the same drop of blood taken from the ear or finger by the stab method can give very variable results even when counted by authorities who are frequently making reports on blood films. The method therefore appears to be unreliable, particularly in tuberculosis where serial hæmograms are desired for their prognostic value. The experiment further suggests that, if comparable results are to be obtained, the blood must be collected by venepuncture, but even with this method care must be taken not to lay too great stress on the count, as seen by the variation obtained when the same slide was counted by different observers.

These facts are probably well known to pathologists, but I feel sure that a number of clinicians will be interested in these tables and the conclusions they indicate.

I am, Sir, yours faithfully,

FREDERICK HEAF.

Colindale Hospital, Hendon, N.W., May 7th.

**ETHER CONVULSIONS**

To the Editor of THE LANCET

SIR,—Having read the article by Dr. Woolmer and Dr. Taylor on Late Ether Convulsions in THE LANCET of May 2nd, I feel that the following case may be of interest. It happened to be treated successfully with Evipan sodium before reading the article.

A well-developed man, aged 20, was admitted to the Leicester Royal Infirmary on May 6th suffering from acute appendicitis, with a history of abdominal pain and vomiting for three days. Before operation his temperature was 101.4° F., pulse 120, respiration 22. Atropine gr. 1/100 was given before operation; nitrous oxide, oxygen, and ether (4 oz.) was administered by the McKesson apparatus, using a carbon-dioxide absorber. A perforated gangrenous appendix was removed; the abdomen contained a large quantity of pus. When the operation was almost completed and the anaesthesia had been in progress for about thirty minutes, the patient began to have short clonic convulsions and was cyanosed during each attack. In the intervals between the fits his colour returned to normal. Ten minutes later the convulsions became tonic and continuous, and the patient remained cyanosed in spite of the administration of oxygen with carbon dioxide. The convulsions became extremely violent, and it was only with great difficulty that the patient could be kept on the table. The administration of chloroform was quite ineffectual in controlling the condition. With some difficulty the arm was held still and evipan sodium injected slowly intravenously. By the time 4 c.cm. had been given the convulsions ceased and the patient relaxed. Oxygen was given by the McKesson mask, and the colour improved. The pulse was poor in volume, but 1.7 c.cm. of Coramine intravenously acted quickly, and the operation was finished in a few minutes.

In this case as in most of the other recorded cases of late ether convulsions there was much sepsis, a high degree of pyrexia, and (I may add) a thunderstorm was in progress at the time of the operation. The convulsions did not recur and up to the present the patient is making a good recovery. His past history was healthy, and there was no family history of epilepsy or of fits.

I am, Sir, yours faithfully,

JAMES S. MARR,

Resident Anaesthetist, Leicester Royal Infirmary.  
May 10th.

### UNDULANT FEVER

To the Editor of THE LANCET

SIR,—In your issue of Dec. 28th, 1935, you were good enough to publish a paper on undulant fever which I read before the Nottingham Medico-Chirurgical Society on Nov. 6th. My attention has been called to a small but important error in this paper and I shall be much obliged if you will give me the opportunity of correcting this. Fig. 2 showed in diagrammatic form the frequency of the commonest 21 symptoms in a series of 200 cases, but in the legend beneath the Figure I referred in error to 300 instead of 200 cases, thus showing a greatly reduced incidence of all these symptoms. I have now analysed the first 300 cases in my records for which I have obtained the signs and symptoms, and the following Table giving their frequency may be of interest to some of your readers:—

Sweating .. .. .	195	Abdominal pain .. .. .	33
Malaise and fatigue .. .. .	180	"    tenderness .. .. .	31
Headache .. .. .	158	Depression .. .. .	30
Anorexia .. .. .	130	Arthritis and arthralgia .. .. .	29
Pain (not in joints, head, or abdomen) .. .. .	126	Rash .. .. .	27
Constipation .. .. .	124	Diarrhoea .. .. .	25
Rigors .. .. .	80	Insomnia .. .. .	25
Enlarged spleen .. .. .	55	Epistaxis .. .. .	21
Cough .. .. .	49	Visual disturbances .. .. .	20
Sore-throat .. .. .	47	Vomiting .. .. .	15
		Nausea .. .. .	13

I am, Sir, yours faithfully,

WELDON DALRYMPLE-CHAMPNEYS.

Ministry of Health, Whitehall, S.W., May 7th.

### ACUTE FEBRILE ANÆMIA

To the Editor of THE LANCET

SIR,—I must offer sincere apologies to Dr. Parkes Weber for quoting a misquotation of his words. I think the expression "acute breakdown of the blood" is quite a useful one. It is more elegant than "erythronoclastic anæmia," a term also used in this connexion. I do not see why an acute breakdown of the erythron should necessarily be associated with hæmoglobinuria. I have never seen a satisfactory explanation of the relationship of hæmolysis to anæmia. It cannot be that they are two manifestations of one process. I am not sufficiently familiar with cases of acholuric jaundice or paroxysmal hæmoglobinuria to quote them, with confidence, as examples of conditions in which hæmolysis is out of proportion to the anæmia, but the case that I described in my paper, which included every feature of the Lederer type of anæmia except hæmolysis, suggests that two processes are concerned in the production of acute hæmolytic anæmia, one of which, hæmolysis, is a concomitant rather than an essential feature. The fact that, in my case, ventriculin seemed to exert its specific effect suggests that it was the make-up of the cells that was at fault rather than their breakdown.—I am, Sir, yours faithfully,

Torquay, May 10th.

PAUL GIBSON.

### RADIOLOGY IN THE CURRICULUM

To the Editor of THE LANCET

SIR,—In the account in THE LANCET of May 2nd (p. 1027) of the report of the Royal Society of Medicine Subcommittee on the teaching of radiology in medical schools, I see no reference to the teaching of this subject in Sheffield. I beg to point out that our regulations insist that before a student can enter for his final examination he must have attended "for three months a course in radiology." We have had on the University staff since 1924 a lecturer in radiology who is honorary radiologist to one of our general hospitals, and even before that date instruction was given by clinical teachers. The course includes lectures and demonstrations in the radiological department. Radiological anatomy is also taught in the department of anatomy during the preclinical period.—I am, Sir, yours faithfully,

G. A. CLARK,

Dean of the Faculty of Medicine, University of Sheffield.

May 11th.

### "A DOUBTFUL CASE OF TYPHUS FEVER"

To the Editor of THE LANCET

SIR,—With reference to the case shortly reported in your issue of Oct. 12th, 1935 (p. 864) and my comment which appeared on March 7th (p. 570), I wish to say that I have now received information from an entirely trustworthy source showing that this case was in fact bacteriologically proven enteric fever. Subsequent tests (not published) demonstrated a high and rising titre to *Bacillus typhosus* (both H and O strains) which, taken with a positive stool culture and absence of all response with Malayan *proteus* strains (Weil-Felix tests), left the matter in no doubt whatever. The diagnosis of sporadic cases of "endemic" typhus occasionally gives us trouble in the East, and that such cases are apt to be overlooked is my excuse for my perhaps too hasty comment on the too brief report which you published.

I am, Sir, yours faithfully,

Hankow, April 17th.

A. H. SKINNER.

### THE FREUDIAN CONFESSIOAL

To the Editor of THE LANCET

SIR,—In view of Dr. Freud's recent anniversary the following quotation from a sermon of St. Gregory the Great, the first Benedictine Pope (590–604) is not without interest: "Quid est ergo peccatorum confessio, nisi quaedam vulnere ruptio? Quia peccati virus salubriter aperitur in confessione, quod pestifere latebat in mente.—Et confitendo peccata quid aliud agimus, nisi malum quod in nobis latebat, aperimus." (Hom. 40 in Evang.)

I am, Sir, yours faithfully,

Dom FRANCIS IZARD, O.S.B., M.R.C.S., L.R.C.P.  
Quarr Abbey, Ryde, Isle of Wight, May 10th.

ROYAL CANCER HOSPITAL.—The annual accounts of this hospital show a deficit of £29,476 on the ordinary account and £5242 on the research account. Annual subscriptions amount to only £4000 and a sum of £60,000 has to be collected to pay expenses, exclusive of research. At the annual meeting held on May 8th, Mr. Cecil Rowntree, the senior surgeon, said that owing to the expensive apparatus presented by Sir Herbert Austin, and the five-gramme radium bomb which was being installed, they had the prospect of being able to effect cures in cases which a few years ago they would have been afraid to attempt.

## OBITUARY

**HAROLD BATTY SHAW, M.D., F.R.C.P. Lond.,  
F.R.C.S. Eng.**

Dr. Harold Batty Shaw, who died on Saturday last at Littlehampton suddenly, held a leading position in London for many years as a consultant physician.

The third son of the late Mr. Edward Walker Shaw of Bradford, he received his education as a boy in New South Wales but came later to the Yorkshire College, Leeds, and then entered University College, London, as a scholar. He gained many honours as a student, among others the Tuke medal and the Erichsen prize, and graduated as M.B., B.S. Lond. in 1895, taking the scholarship and gold medal

DR. BATTY SHAW

[Photograph by Elliott &amp; Fry

in the B.S. examination. In 1897 he was Atkinson-Morley surgical scholar. He proceeded to the M.D. degree, taking also the diploma of F.R.C.S. Eng., and held the interne appointments at University College hospital. He became demonstrator of anatomy in the school, and resident medical officer to the hospital, and was elected in 1900 assistant physician to the hospital and later assistant physician to the Brompton Consumption Hospital.

At the Royal College of Physicians of London he was elected F.R.C.P. in 1905, delivered the Goulstonian lectures in the following year, and was an examiner for several years in medicine at the Conjoint Board. He served also as examiner in medicine at Oxford. Elected physician to University College hospital, he was lecturer on clinical medicine and therapeutics in the school, where he also served as dean.

Batty Shaw showed an original bent for surgery, as is indicated by his scholastic record, but he served as house physician to Sidney Ringer and was imbued with that great physician's love of research. In those days it fell to the lot of the resident medical officers of the hospital to perform the post mortems and conduct other investigations in clinical pathology needed by the staff. In these directions Shaw worked assiduously, and early in his career made a mark with contributions to the professional journals over a wide range of subjects. He wrote on acute leukaemia, then a rare subject in medical literature, in collaboration with Rose Bradford, and on erythromelalgia and certain developments of diphtheria. He contributed the articles on food poisoning and pulmonary hypertrophic osteo-arthritis to Allbutt and Rolleston's "System of Medicine," and in the pages of the *British Medical Journal* summarised the evidence for and against the use of tuberculin as a specific cure. He wrote also a book on organotherapy as early as 1905, which formed a good summary of the work done up to that date with regard to the physiology of the ductless glands and the use of

organic preparations. In opening important and in many directions new ground, he wrote with great fairness as can now be seen, though at the time he appeared to be merely cautious. He allowed the facts as he recorded them to speak for themselves and showed little dogmatism in speaking of the value of organotherapeutics in various diseases. Readers at the time may have felt that they wanted more guidance, but we can see to-day many things which might have been put in through superficial deductions, and would later have been corrected. A similar attitude of caution marked his learned Goulstonian lectures upon the relations of auto-intoxication to the disturbances of blood pressure. The lectures were based largely on personal observations on the use of the sphygmomanometer, and his aim was to present elaborate physiological processes in a way that would serve practical medicine. In his book, "Hyperpiesia and Hyperpiesis," published in 1922, Batty Shaw showed his independence of thought and critical spirit while giving the results of exact clinical information controlled by post-mortem examination. The work was essentially the record of one man's experiences, and singleness of vision was not complicated by the numerous and conflicting observations and opinions of other workers in this field of medicine.

Dr. Charles Bolton writes: "He was a man of quite extraordinary energy and enthusiasm, which characterised all his activities not only in the various aspects of his work, but in everything that he undertook. The same qualities have been displayed at all stages of his career from a student to the end of his life, for he has died in harness—a death he would have chosen; and one might have foretold that his end would be sudden and whilst he was actively engaged in work. His selection of his life's work was characteristic. Having decided, under Ringer's influence, to take up medicine rather than surgery he was ever afterwards an indefatigable worker and his endeavour was from start to finish to give the best of which he was capable to the hospital to which he was a physician, and to his profession. He succeeded well in this endeavour, which he carried out with great industry and honesty, and he merited the warm esteem of all. He took infinite pains in his teaching without any thought whatever of trouble; but he did more than this for the students, for his example exerted an influence for good in all respects; and when he resigned from the hospital they felt that they had lost not only a very popular teacher and sound general clinician, but a very real friend. A man of this striking personality and breezy activity could not avoid now and again making a hasty judgment and perhaps raising the dust about his ears; but such was his good nature and his prompt acknowledgment of an error that it soon ended amicably with pleasant chaff. When University College was taken over by the London University, it was necessary to build a medical school for the hospital. Funds were not available wherewith to carry out this project, and it stands entirely to the credit of Shaw that, through his influence, Sir Donald Currie presented the money to build the school."

At the time of his death Dr. Batty Shaw was consulting physician to University College hospital and the Brompton Hospital. He married Agnes, daughter of the late Rev. Patrick Watson, who survives him with a daughter and son.

**ARTHUR EASTWOOD, M.A. Oxon., M.A. Camb.,  
M.D. Lond.**

ON Tuesday, May 5th, after a few hours' illness, Arthur Eastwood died in his sixty-ninth year. Manchester born, he was one of the brilliant group who studied fifty years ago at the famous grammar school of his native city, among them our present Lord Chief Justice. After greats in philosophy at Oxford, Eastwood's career might have taken almost any of the channels which a profound scholarship and an innate lucidity of thought laid open to him. To those who knew him in his prime it often seemed that an academic chair or the higher branches of the law would have been the proper setting for his acute intellect and grasp of detail. It is rare for such a training to turn a man to medicine but, when it does, we have such a man as Eastwood was. To Michael Foster, primarily, this turning was due, for it was Foster's philosophic outlook on the institutes of medicine, as physiology was once so happily entitled in the Scottish schools, that led Eastwood to Cambridge and an unceasing devotion to science as applied to the study of human disease. On completing his clinical studies at St. Bartholomew's Hospital, he graduated in 1901 M.B. of London University, and in the following year M.D. with a thesis on the malignant tumours originating from adrenal remnants. It was this, no doubt, which led the Royal Commission on Tuberculosis to call upon Eastwood when in January, 1903, they felt the need of a first-class histologist to study the tissue reactions in their experimental material. For nearly seven years he worked in the "Royalcot" Laboratory, built for him at Stansted, Essex, making up with Cobbett and the brothers Griffith the team of investigators which did so much to render the Commission's Report a monument to British scientific thoroughness and a quarry from which have been dug most of the foundation-stones of later work on the bacteriology of tuberculosis.

When in 1909 the Commission came to an end, there remained some outstanding questions still to answer, notably on the part played by bovine tuberculosis in the causation of tuberculous infection in children and on the degree of infection with tubercle bacilli of the meat of tuberculous pigs. Eastwood was appointed on Newsholme's advice to deal with these questions, was given the post of Inspector to the Local Government Board, and called upon to found the Board's pathological laboratory. This he did, and to his guiding hand is owed much of what credit has accrued to the laboratory—later the laboratory of the Ministry of Health—during the subsequent 23 years in which he was its head. One of the earliest tasks of the new laboratory was to investigate the outbreak of rat plague in East Anglia in 1911; Eastwood's report (with F. Griffith) will remain a graphic picture of one of the most curious manifestations of that mysterious pestilence, bubonic plague. But it hardly reveals the power of organisation and of dealing with local difficulties, human and material, which Eastwood had to display. Few men could have gained, as he did, enthusiastic co-operation, alike from the village constable, the farm labourer and the country squire.

On the outbreak of war in 1914 the Laboratory tackled the problem of epidemic cerebro-spinal fever which Newsholme's epidemiological flair foresaw as the necessary consequence of the mass congestion of army life. Eastwood's report on the meningococcus carrier problem with its insistence on the extraordinary proportion of carriers among "non-contacts,"

though it clashed with previous conceptions and was not immediately acknowledged as the true picture, became the basis of administration for civilian health authorities in this disease.

In later years Eastwood's philosophical bent was manifested in a long series of articles in the *Journal of Hygiene* on immunological problems. It was a disappointment to him to find how little interest the post-Ehrlich generation of pathologists took, and how small their effort was, in attempts to synthesise and establish a co-ordinating hypothesis for the ever-increasing body of observations on immunity in its widest sense. Some, at least, of Eastwood's hypotheses will inevitably be recalled with admiration when the day comes for immunity to yield up its final secrets. He had hoped, in the leisure of his retirement which began three years ago, to express his views in a conspectus of immunology in general and it is to be hoped that enough of this had been achieved to permit of its publication, at least in skeleton form.

Not the least important of Eastwood's activities during his long official life was the giving of advice on bacteriological questions to the administrative staff at the Local Government Board and Ministry of Health. Whether in consultation or by official minute, his replies were always models of clarity; his caution was equalled only by the firmness with which he would maintain and express an opinion which he felt was just. No doubt to the eager reformer and innovator he might appear cold and unresponsive; he was, in fact, by nature reserved and even perhaps intolerant of what he regarded as ill-founded enthusiasm. But to Eastwood thought must be grounded on strict logic and an opinion once formed, on the full consideration which no one knew better than he how to give, was almost sacred and certainly not lightly to be challenged.

He had little liking for even semi-public appearances. Though one of the founder-members of the Pathological Society of Great Britain and Ireland, he rarely attended its meetings and scarcely ever spoke. At one time he regularly reviewed scientific publications for the *British Medical Journal*; his style was unmistakable; it was, in fact, a common remark that Eastwood's account of a scientific paper was not only much shorter but much better than the original. His familiarity with the literature, especially that of immunology, was probably unequalled, and in that field his surviving colleagues will miss his aid perhaps more than in any other.

His private life was simple, almost austere. Left a widower when quite a young man, he did not remarry. He had few interests outside his work, though to the end his leisure hours went to the tending of his garden in which he knew almost intimately each plant and flower. To the few who knew him well, he would give freely out of his store of memories of academic and official life and to them his death has come as a divorce from exceptional intellectual richness and urbanity.

W. McD. S.

**DAVID MIDDLETON GREIG, M.B., F.R.C.S.,  
F.R.S. Edin.**

WE announced last week the death of Mr. David Greig, who for the last 15 years had been conservator of the museum of the Royal College of Surgeons, Edinburgh. He received his medical education at the University of Edinburgh where he graduated in medicine in 1885, taking also the diploma of F.R.C.S. Edin. He practised at first as assistant

to his father in Dundee and then filled for a time an appointment to the James Murray Royal Asylum, Perth, and then became medical superintendent of the Baldovan Asylum for Imbecile Children. Later he decided to practise in surgery and became demonstrator of anatomy and lecturer on clinical surgery at University College, Dundee, and assistant surgeon to the Dundee Royal Infirmary. But he preserved his interest in psychiatry, and his investigations into the material collected at Baldovan definitely advanced knowledge of certain problems of mental deficiency.

The outbreak of the South African War found Greig an officer in the Forfar volunteer artillery. He served in the R.A.M.C. throughout the war with the rank of major and received a medal and two clasps. At the close of the war he became full surgeon to the Dundee Royal Infirmary and acted as examiner in surgery at the University of St. Andrews, while he also made interesting surgical communications to the *Edinburgh Medical Journal*. While still actively engaged in surgical work, he retired from practice to devote himself to studies of a more purely scientific nature. Fifteen years ago he was appointed curator of the museum of the Royal College of Surgeons of Edinburgh and his work in that capacity has greatly added to the value to the profession of the material stored in the museum. His name in recent years has been chiefly associated with researches into the pathology of diseases of bone, and his recent publication on the "Surgical Pathology of Bone" was the fruit of extensive observation and study. Both the Universities of Edinburgh and St. Andrews conferred on him the honorary degree of Doctor of Laws in recognition of the value of his work.

**ANDRÉ JOHN MELLY, M.C., M.B. Oxon.,  
F.R.C.S. Edin.**

THE tragic death of Dr. Melly in the British Legation at Addis Ababa on Tuesday, May 5th, has awakened feelings of the deepest regret. The tragedy occurred as a result of a wound sustained during the riots following the fall of the city.

André John Mesnard was born in Liverpool in 1899, the younger son of the late Col. Hugh Melly, and was educated at Marlborough. On leaving school he entered the Royal Artillery as a subaltern, served in France during the war, and was awarded the M.C. On demobilisation he went up to University College, Oxford, where he studied medicine. He completed his medical training at St. Bartholomew's Hospital, and graduated in 1929 as M.B., B.Ch. Oxon. He served as house surgeon at St. Bartholomew's Hospital and at the Hampstead General Hospital, and having visited Canada and the United States, held for a time the post of surgical instructor at Michigan University Hospital.

Melly had for many years manifested his ardent religious convictions, and while an undergraduate at Oxford he used to preach at the Martyrs' Memorial on Sundays. A deep interest in missionary work came natural to him, and when some two years ago he heard that there was an opening in Abyssinia for these efforts he made two visits to the country. He interviewed the Emperor and as a result gained his support and that of his advisers for the establishment of a medical mission in Ethiopia, but by that time the political situation put an arrest to any such project. But he learned of the need of the Ethiopian Government for a Red Cross service, and returned to London to obtain backing for the project. It was entirely owing to Melly's enthusiasm that the

Abyssinian Red Cross ambulance was initiated. He left for Abyssinia in November last as head of the first unit of the British Ambulance Service, accompanied by five doctors, an armed guard consisting of 12 ex-privates of the King's African Rifles and a few other men, one of whom was a Canadian and

Mr. Melly on service in Abyssinia

one a Dane. They took with them tents to be used for the conduct of operations specially designed so that they could be erected and dismantled in the briefest possible time, and from the time of their arrival in Ethiopia he and those serving with him in the unit went in grave risk of death. Melly himself had many escapes, his camp being bombed in January and again in March. On the latter occasion, which occurred at Quoram, there were in the ward-tents many serious cases and Melly himself was operating when the Italian planes began dropping bombs. Several of the tents were destroyed and unfortunate inmates killed. Melly himself had no doubt that the bombing of the tent was intentional inasmuch as the camp was indicated by an enormous red cross. He received a fatal wound during the riot of drunken looters which occurred in Addis Ababa on the Sunday following the departure of the Emperor. His car was attempting the rescue of a wounded Abyssinian when he was shot through the lung and died 48 hours afterwards.

From personal notes of Melly's career received here we may select the following:—

G. F. R. S. writes: "It was entirely owing to Melly's enthusiasm that the Red Cross Ambulance Unit was initiated though, with characteristic modesty, he kept in the background, but it is safe to say that if it had not been for the work done by him and his sister, this unit would never have taken the field. Although John Melly had this serious side to his character, he was brimful of fun and joie de vivre. To know him was to love him, and it is sad to think that we shall not hear again the infectious laughter which characterised his gay and gallant spirit. His elder brother was killed at Beaumont Hamel in 1916."

Another personal tribute is as follows: "Dr. A. J. M. Melly, known to everyone as John Melly, was an outstanding personality. He was striking in every way, his appearance, his behaviour, his charm

of manner, and his ideals; and even as an undergraduate it was obvious that he would not run in any of the ordinary paths of medicine. In appearance he was good to look upon, striding along 'beautifully' dressed, hat in hand and above all his open ever-cheerful face. But there was another side to his appearance which many may not have seen—in the boxing ring, where he was a first-rate performer, his wonderful physique, perfectly controlled, was a sight not easily forgotten. His cheerful enthusiasm was remarkable at all times. When out in Abyssinia on an occasion previous to the Italo-Abyssinian war he developed a neuritis which was followed by a paralysis completely incapacitating his hand. Though the prospect of recovery seemed far from good, his cheerfulness and spontaneous gaiety which had always drawn to him a host of friends remained unchanged. The unexpected occurred—the paralysed muscles began to move the day before an operation had been planned for exposure of the nerve, and this was followed by a full return of function. He then threw himself into the hard work of making preparations for taking out the first Red Cross unit to Ethiopia. Truly of John Melly it may be said that 'A merry heart maketh a cheerful countenance.' His laughter was so typical and infectious that to those who knew him it will ever continue in their ears reminding them of a remarkable Christian English gentleman."

#### PROF. J. G. CATTANACH

Dr. Robt. Hutchison sends the following appreciation:

"Dr. Cattanach occupied a unique position in the medical world of Edinburgh for he might have been described as a 'character.' He began the study of medicine rather late in life, his earlier years having been spent in business in London, but in spite of this initial handicap he became an accomplished clinician with a very sound judgment in diagnosis; being entirely devoid of worldly ambition, however, and having many other interests, he never reached the professional success to which his abilities entitled him. None the less, he had a position and a success all his own. His genial personality and his wide interests in literature, art, and sport won for him a

host of friends and all who knew him loved him. He was very widely read and had a most retentive memory and being also gifted with the graces both of wit and humour, was a delightful companion, and never more so than on a fishing or golfing holiday. Throughout his long life he retained his keen enjoyment of the human comedy and was the guide, counsellor, and friend of any who were in trouble, and especially of the young. Although much crippled by gout in his later life he never gave in, and only last year set off alone on a trip to Palestine. He went down in the end with his flag flying and has left to his many friends the memory of perhaps the most kindly and lovable human being they ever knew."

Dr. JOHN WILLIAM JACKSON, who died recently at Esher, was a native of Glasgow and graduated at the university as M.B., C.M. in 1895. He was for a time resident physician at the Royal Infirmary, Glasgow. He then went to China and was in practice there when the war broke out. He took a commission in the R.A.M.C. and was stationed at Malta, but at the direction of the Foreign Office returned to Shanghai where he later became surgeon to the Imperial Maritime Customs, acting also as Admiralty surgeon and agent with quarters in Shanghai. He was during this period of invaluable assistance to the China Inland Mission, and on his return to England and private practice in London he kept up his interest in the mission and gave valuable voluntary help at a nursing-home in London connected with it. He was a sound practitioner and philanthropic man.

FREDERICK PERCY ROSE, L.M.S.S.A., who recently died from heart failure, had been a medical practitioner in St. Ives, Huntingdonshire, for more than 30 years. The son of the British Consul at San Remo, he was born in Italy where he spent his childhood. He received his medical education at the London Hospital and went into practice at St. Ives where he succeeded to and enlarged an old practice. He served on the St. Ives town council and was mayor of the borough in 1929 and took a keen interest in public affairs throughout a busy life.

## PANEL AND CONTRACT PRACTICE

### Sickness in Scotland

THE continued gradual recovery in employment since the depression of 1931 is reflected in the increase of contribution receipts for insurance purposes shown in the recent report of the Scottish Department of Health. These in 1935 were 6 per cent. greater than in 1934, 8.6 per cent. greater than in 1933, and 12.7 per cent. greater than in 1932. At the same time the incidence of incapacitating sickness is rising among the insured population of Scotland. The fifth of a series of annual surveys, which will shortly be available, shows substantial increases for 1934-35 compared with 1933-34 in both (a) the number of individual cases of incapacity completed during the year, and (b) the aggregate number of days of incapacity relating to these cases. Compared with 1932-33, however, there is a decrease under (a), coupled, however, with an increase under (b). The increase over 1933-34 is mainly attributed to the influenza epidemic in the spring of 1935 which accounted for the entire increase in the total number of cases, and for nearly half of the total increase in the aggregate duration of incapacity. The epidemic had two exceptional features: in the first place its

virulence was greatest in the normally very healthy rural areas from Kincardine round the Moray Firth to Caithness; in the second place, after the passing of the epidemic, the sickness-rate remained relatively high, whereas as a rule an epidemic is followed by a period of relatively low sickness. There was some increase also in a number of other diseases, particularly bronchitis and subacute rheumatism; an upward tendency has been noted during the past four years in diseases of the ear, myocarditis, diseases of arteries, mastitis, boils and ulcers, muscular rheumatism and lumbago, brachial neuritis, and nervous debility. The number of insured persons incapable of work throughout the whole of the year has shown a steady increase from year to year. The figures are: 1931-32, 22,287 cases; 1932-33, 26,059 cases; 1933-34, 27,224 cases; 1934-35, 29,504 cases.

### Prescribing for Insured Persons

The same report contains an interesting excursus on the use of drugs. Although drugs are potent weapons against disease when administered under skilled direction, they do not, it is suggested, as a rule alone constitute treatment. No amount of

medication, for example, can cure dyspeptic disorders where the causal element is an unremedied violation of the fundamental dietary laws. There is reason for concern at the widespread incidence of peptic ulcer and of those minor gastric disorders which form the early stages of this condition, but there is ample evidence, especially in industrial areas, that the public place too much reliance upon medication for the cure of such disorders and pay too little regard to the counsels of their medical advisers as to discipline of diet and of habits. In the Department's view there is an urgent need for further education of the public in these matters, and they feel that the family physician, by the exercise of his professional authority and prestige, can do much to inculcate the paramount importance of proper dietary, habits, and hygiene, not only from the point of view of maintaining health but as an integral part of curative treatment.

During the year ended Sept. 30th, 1935, the average cost per insured person in Scotland of drugs and appliances was 24.20 pence. This compares with 23 pence in the previous year. As in previous years, great variations existed as between different areas and between doctors' costs within an area. On the recommendation of local panel committees, three doctors were surcharged during the year for excessive prescribing, the surcharges aggregating £45 5s. The

Department seeks to restrain the tendency towards unnecessarily expensive and excessive prescribing, and note with satisfaction that the principles and rules for economical prescribing recently laid down by the International Labour Office are substantially on the lines that have been in operation in Scotland for many years.

The question whether certain specified vitamin concentrates are drugs for the purposes of medical benefit was referred to the advisory committee, which advised that (a) vitamin concentrates must be considered as drugs for the purposes of medical benefit in cases presenting evidence of definite diseases due to vitamin lack, but such cases are rare among adults in this country; (b) unless there is evidence of definite disease due to vitamin lack, vitamin concentrates must be considered as food substitutes rather than drugs, and their cost should not form a charge on N.H.I. funds; and (c) as a general rule a vitamin concentrate should not be used unless there is definite evidence that its vitamin content has been accurately estimated and is clearly stated in recognised units. The committee points out that vitamin concentrates are commonly prescribed in cases of ill-defined ill-health, whereas if there is a vitamin deficiency in such cases, the natural and most satisfactory method of increasing the vitamin supply is to improve the dietary.

## PUBLIC HEALTH

### Some Problems of Midwifery

At the annual meeting on May 6th of the National Birthday Trust Fund report was made on Mrs. Baldwin's appeal for an investigation into the question of an analgesic for use in confinements not attended by a doctor. The inquiry by the British College of Obstetricians and Gynaecologists, which was the result of this appeal, made it clear that, while analgesia is not harmful to either mother or infant, the College could not give unqualified approval to the administration of chloroform capsules by midwives. The College did however regard gas-and-air administration by the Minnitt apparatus as a safe and satisfactory method, the drawback being that the apparatus is expensive and the gas costly. The report of the Fund notes that efforts are being made to meet this criticism by producing a cheaper and more portable machine. The price of the Minnitt machine used in the tests, viz., £16 16s., should be within the means of small hospitals, as it is suitable not only for maternity work, but also for minor operations and painful dressings. The cost per case of gas as worked out by the Wellhouse Hospital is 2s., the British Hospital for Mothers and Babies at Woolwich reports the outlay as 2s. or under, and in general the cost does not seem to have exceeded 3s.-4s. a case. The British Oxygen Company is now supplying nitrous oxide at 5s. per hundred gallons for individual orders and at a cheaper rate for hospitals and institutions.

Two other investigations have been financed by the Fund. The first of these was to determine the influence of malnutrition on childbirth. The average maternal death-rate in the Rhondda urban district and the Llantrisant and Llantwit Fardre rural district for eleven years up to 1933 was 6.2. In 1934 the figure rose to 11.3 with a total rate from all causes of 14.5 in spite of an improved medical service established that year. In 1935 an experimental distribution of free foodstuffs in the shape of Blandox, Ovaltine, and Marmite was provided over a period

of three months to necessitous expectant mothers. The maternal death-rate fell to 3.9, or a total death-rate from all causes of 4.8. Impressed by these figures the Fund approached the Commissioner for Special Areas for a grant to enable the scheme to be extended. A gift of £2500 from the Marquess of Bute has provided for a continuance and extension of the work in S. Wales, and a grant of £3000 from the Commission for Special Areas has been allocated for similar distribution of foodstuffs in South Shields, Sunderland, Gateshead, Merthyr Tydfil, and the scheduled areas of Monmouthshire. At the suggestion of the Ministry of Health more milk food is to be given. The second investigation was made with the assistance of the M.O.H. for the Rhondda Valley to determine the value of an efficient non-poisonous antiseptic. For the two years 1934-35 midwives in the valley were given a free supply of Dettol disinfectant. The incidence of sepsis in 1935 was 1.06 per cent. in cases in which this disinfectant was used, compared with 3.17 when it was not used.

### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED  
MAY 2ND, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 3 (Brighton 2, Hove 1); scarlet fever, 2028; diphtheria, 911; enteric fever, 22; pneumonia (primary or influenzal), 941; puerperal fever, 35; puerperal pyrexia, 129; cerebro-spinal fever, 22; acute poliomyelitis, 1; acute poliomyelitis, 1; encephalitis lethargica, 5; continued fever, 1 (Battersea); dysentery, 14; ophthalmia neonatorum, 98. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 8th was 6128, which included: Scarlet fever, 1021; diphtheria, 874; measles, 2933; whooping-cough, 557; puerperal fever, 19 mothers (plus 14 babies); encephalitis lethargica, 283; poliomyelitis, 4. At St. Margaret's Hospital there were 25 babies (plus 10 mothers) with ophthalmia neonatorum.

## PARLIAMENTARY INTELLIGENCE

### SILICOSIS IN SOUTH WALES

LAST week in the House of Commons several exchanges betrayed the deep interest felt in the occurrence of silicosis among the miners of South Wales. Mr. JAMES GRIFFITHS asked the Secretary for Mines whether he was aware that since 1931 the Silicosis Medical Board had issued certificates of disablement or suspension to 709 miners from the South Wales coalfield, and that in the same period the deaths of 147 miners were certified to have been due to silicosis; and, in view of the spread of this disease among the miners in South Wales, what steps he proposed to take to enforce measures to prevent the contraction of the disease by the workmen employed in the mines. Dr. BURGIN, Parliamentary Secretary to the Board of Trade, replied: My hon. friend is kept fully informed of the mine and quarry cases which are dealt with by the Silicosis Medical Boards in all parts of the country and the information is used as a guide for preventive action. The gravity of the figures for South Wales has been fully appreciated, and in reply to a question on Feb. 13th my hon. friend indicated the measures which have been taken and are still in active progress both to extend the use of preventive methods already available and to develop new and improved measures.

Mr. GRIFFITHS: Will the hon. Member make sure that the men's representatives, who have a wide experience in this matter, are consulted? My information is that no representative of the Department has had a single consultation with the representatives of the men.

Viscountess ASTOR: Will the Parliamentary Secretary inform the House that he is doing all he can in this matter? The question has been before the House for 17 years and so far the numbers are going up instead of down.

Dr. BURGIN: The House will probably like to see the matter dealt with more fully by reading the evidence tendered to the Royal Commission by the Mines Department which is now published on pages 13 and 14 of the Report of the Royal Commission of Feb. 10th last.

Mr. E. J. WILLIAMS: Will the Department in conjunction with the Home Office see that a new Order is issued speedily so that the men may have compensation in the meanwhile?

No further answer was given.

Mr. GRIFFITHS then asked the Home Secretary whether he was aware that out of 691 applications made by miners from South Wales to the Silicosis Medical Board for certificates of disablement or suspensions during 1934 and 1935, no fewer than 311 of these applications were refused such certificates, notwithstanding that each of these workmen had been certified by their panel doctors and by the regional medical officer of the Ministry of Health to be suffering from silicosis or anthracosis; and what steps he proposed to take to so amend the provisions of the various Industries (Silicosis) Orders, 1931 to 1934, as to make it possible for these workmen to claim compensation for the disablement which arose

*(Continued from previous page)*

*Deaths.*—In 122 great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 83 (38) from measles, 8 (3) from scarlet fever, 32 (9) from whooping-cough, 31 (5) from diphtheria, 42 (17) from diarrhoea and enteritis under two years, and 64 (11) from influenza. The figures in parentheses are those for London itself.

Measles is now probably on the wane, the number of deaths for the last eight weeks (working backwards) being 83, 104, 102, 103, 81, 104, 114, 105 for the country as a whole, and 55, 70, 68, 60, 43, 62, 62, 58 for Greater London. Deaths from diphtheria were reported from 17 great towns, 4 each from Hull and Manchester. Portsmouth, Sunderland, and Leicester each had 1 death from enteric fever.

The number of stillbirths notified during the week was 258 (corresponding to a rate of 36 per 1000 total births), including 45 in London.

from and was caused by the inhalation of coal and stone dust in the course of their employment. Mr. GEOFFREY LLOYD replied: I am aware that there have lately been a considerable number of cases of miners suffering from lung troubles which the expert Medical Board could not find to be silicosis. It is impossible, in the present state of knowledge, to tell whether or how far they may have been due to employment, but the matter is being investigated by the Industrial Pulmonary Diseases Committee of the Medical Research Council. Consideration of further action must await results of such research. I should add that under the arrangements made with the Ministry of Health, the Regional Medical Officer does not diagnose and certify silicosis but merely conducts a preliminary examination to ascertain whether there is reasonable cause to support the presence of the disease.

Mr. GRIFFITHS: Seeing that the Ministry of Health doctor is satisfied that these men's illnesses are affected by their employment will the Minister see that the scheme is so widened as to bring these men within the compensation law, in view of the fact that they have been certified by the Ministry of Health doctor.—Mr. LLOYD: I do not know whether the hon. Member appreciates the fact that the regional medical officers' function is to certify only when there is cause to suspect silicosis. The Home Secretary's powers are limited under the Act to making schemes for silicosis.

Mr. GRIFFITHS: I appreciate that, but does the hon. Member appreciate the fact that 311 suspected cases turned down in three years is alarming and calls for a widening of the scheme.—Mr. LLOYD: That is why the medical aspect of this matter, which must be settled before we proceed further, must be investigated.

Mr. PALING: The Medical Board have been inquiring into this matter for a long time. Can the Minister say how soon they are likely to report.—Mr. LLOYD: I cannot say how long they have been inquiring, but it is very difficult research and will take some time.

Mr. ROWSON: Can the Minister say how many of the cases turned down have been diagnosed as tuberculosis cases.—Mr. LLOYD: Not without notice.

Mr. LEACH: In view of the Minister's own statement as to the restricted powers of the Home Office will he not ask his Departmental chief to promote legislation to remedy it.—Mr. LLOYD: Before that question can arise the medical aspect of this matter must be settled beyond reasonable doubts.

### NOTES ON CURRENT TOPICS

#### Debate on the Midwives Bill

Speaking late in the debate on the second reading of the Midwives Bill on April 30th, Captain G. S. ELLISTON expressed surprise that general approval had been given by previous speakers to the view that county councils were the proper authorities to be entrusted with the powers under the Bill. It was, he said, a significant fact that, with a few understandable exceptions, all the representative public health organisations contended that where the local supervising authority is not responsible for administration under the Maternity and Child Welfare Act of 1918, the local authority which was administering that Act should also be responsible for the service of midwives provided under this Bill. In other words, they urged that this midwifery service should be an integral part of the maternity and child welfare schemes. The principle involved, he remarked, seemed to have been recognised in the new Public Health Bill. That Bill expressly authorised the Minister to transfer functions to the welfare authority if such transfer would conduce to the more efficient administration in the district of functions relating to public health. It could be argued that such provisions would justify the Minister in placing midwives under the maternity and child welfare authorities. The reasons for this claim were obvious. The health visitors of the maternity and child welfare

authority were able to give the health department early information of pregnancy. It was the health departments which provided antenatal care in clinics, consulting medical services for difficult cases and under the puerperal fever regulations, and those ancillary services, so important in maternity work, such as the provision of milk and meals for necessitous mothers.

The Bill is still under discussion in committee.

#### Voluntary Hospitals (Paying Patients) Bill

In the House of Commons on May 8th when this Bill was being considered on report Sir A. WILSON moved an amendment providing that hospitals under the Bill should not only have to go to the Charity Commissioners in connexion with schemes but also obtain the consent of the Ministry of Health. There was, he said, a steady growth throughout England and Wales of paying patients wards. The pressure on hospitals to make both ends meet by taking in paying patients was increasing, and the Bill was an attempt to make it easier for them to do so in competition with State hospitals. The time had come when the Ministry ought to decide, after full consideration, whether *paying* patients of a particular type should be concentrated in a particular hospital, or whether there should be redistribution of responsibilities.—Mr. GLEDHILL seconded the amendment, and Sir P. HARRIS agreed that the Ministry of Health or the local authorities should be brought in in some way or another.—Mr. STOREY said that under the Bill there was a general safeguard that the available facilities for ordinary patients should not be diminished, and the amendment was withdrawn.

A further amendment by Sir A. WILSON to give county or borough councils some say before the Charity Commissioners exercised their statutory duty in sanctioning a scheme was negatived by 75 votes to 68.

The report stage being concluded, on the motion for the third reading of the Bill, Mr. STOREY said that the measure was promoted by King Edward's Hospital Fund and by the British Hospitals Association to enable hospitals with trust deeds settled long ago to meet the modern demand for pay beds in which those who could afford to pay a moderate charge might receive the benefit of those modern methods of diagnosis and treatment which could not be undertaken without the specialist skill and staff of a general hospital, or could only be undertaken elsewhere at very great expense, if at all. Voluntary hospitals with modern trust deeds could and should provide for all who needed hospital treatment, whatever their capacity to pay. As in the past, their first duty should be to treat free of cost all cases of the sick poor, but after that, they should provide for those persons who could afford the charges which were made elsewhere, and who, but for the provision of paying beds, would have to be treated in the ordinary ward. They should also provide for the other classes who could afford to pay charges proportionate to their means and who could not obtain the treatment they needed anywhere except in a general hospital. But there were many hospitals with ancient trust deeds which could not legally make such provision even with money specially collected or given for the purpose, and when on occasion they had to give treatment which could not be given elsewhere they could not legally charge for that treatment, even though the recipient might be able and willing to pay. Such a state of affairs was not fair to the hospital or to the people of the district served by the hospital. This Bill therefore gave to the Charity Commissioners the power to remove such anomalies by allowing hospitals to provide pay beds provided this was not done to the detriment of their first duty, treatment of the sick poor. No hon. Member need have any fear that in voting for the Bill he would endanger the treatment of the sick poor.

Mr. MATHERS said he hoped that the passage of this Bill for England and Wales would not make the

Government consider that they had any right to proceed with a similar measure for the voluntary hospitals of Scotland.

Sir ALAN ANDERSON said the voluntary hospitals were created, and they all existed primarily to serve the sick poor for whom they had done enormous work; and they had further work to do in seeking out causes of disease and promoting health. But the provision of health was getting more and more expensive, and without help from all the patients the hospitals would have broken down. In his view, and in the view of those who gave up their lives to organising this great charity, it would assist the hospitals to help the sick poor if this Bill was passed.

The Bill was read the third time by 153 votes to 19.

#### Employment of Women and Young Persons

On May 12th the House of Commons considered the Employment of Women and Young Persons Bill, as amended in Standing Committee, on the Report.

Mr. R. J. DAVIES moved a new clause, providing that an advisory committee of eight persons, representing equally the interests of employers and workpeople, should be appointed by the Home Secretary whose duty should be to advise the Home Secretary generally as to the operation of the Bill and in particular as to any complaints which might be received regarding the operation of any authorisation under the Bill. He said that large numbers of employers and workers disliked the two-shift system.

Sir JOHN SIMON opposed the amendment. He said that if there were a complaint which would justify forthwith the cancellation by the Home Secretary of the authority he had given, the clause would prevent him from dealing at once with such a complaint and he would have to allow an admitted evil to go on until he could call the statutory committee together to advise him. It would be better to have such a committee set up with a much more flexible constitution than even the most carefully drafted clause could devise. It would be most unwise to try to define this committee in these set terms at present.

Dr. HOWITT said that the Departmental Committee of which he was a member were in favour of setting up a committee to advise the Home Office, and he for some time could not understand why provision for such a committee could not be inserted in the Bill. It was perfectly obvious that the composition of the advisory committee as suggested in the amendment would not do, and that the Home Secretary should have power to vary its composition in order to deal with different matters as they might crop up. Hon. Members wanted, as he did, to safeguard the workers and to make a success of the double shift system. He had never heard of any deleterious effects on the health of persons who worked under the double shift system. Indeed, by granting such a system they would make it much more certain that good conditions did prevail. He hoped that the amendment would not be pressed, because it was not in the interests of the workers.

The amendment was negatived. The Report stage was concluded and the Bill was read the third time.

#### Vivisection of Dogs

In the House of Commons on Tuesday, May 12th, Sir ROBERT GOWER presented a Bill to prohibit the vivisection of dogs. The Bill was read a first time.

### HOUSE OF COMMONS

WEDNESDAY, MAY 6TH

#### Midwives Bill for Scotland

Mr. MATHERS asked the Secretary of State for Scotland in view of the introduction of the Midwives Bill for England and Wales whether it was his intention to promote legislation for the purpose of reducing the maternal mortality-rate in Scotland; and, if so, when.—Colonel COLVILLE, Under-Secretary of State for Scotland, replied: Yes, Sir.

My right hon. friend hopes to be able to make a statement on this subject at an early date.

#### Dust in Card-rooms

Mr. SUTCLIFFE asked the Home Secretary if he could now make any statement regarding the question of dust in card-rooms in the cotton industry.—Mr. GEOFFREY LLOYD replied: I received a deputation last week from the Amalgamated Association of Card, Blowing, and Ring Room Operatives who were asked in the first instance to send certain further information which would help my right hon. friend in considering the next step. I cannot say more at the moment.

THURSDAY, MAY 7TH

#### Delinquents and Psychological Treatment

Mr. BENSON asked the Home Secretary whether he was yet in a position to make any report upon the work of the psychiatrist appointed to deal with delinquents.—Mr. GEOFFREY LLOYD replied: As is indicated in the recently published report of the Prison Commissioners, this work is still in an experimental stage, and the material obtained will require careful analysis before any conclusions can usefully be formulated. It will not, therefore, be possible to issue any report for some time to come.

#### Local Authorities and Veterinary Surgeons

Mr. SERVINGTON SAVERY asked the Minister of Health how many whole-time veterinary surgeons had been appointed by county and county borough councils during the last 12 months; and whether he was willing to recommend that such councils should, as far as possible, utilise the services of veterinary surgeons who were practising in their districts.—Sir KINGSLEY WOOD replied: I regret that I am unable to give the information asked for in the first part of the question. As regards the second part, my hon. friend is no doubt aware that the Cattle Diseases Committee of the Economic Advisory Council recommended that local authorities should appoint whole-time veterinary officers wherever this is practicable, and I do not think therefore I should be justified in taking the course suggested.

#### Rural Sewage Disposal Schemes

Sir RALPH GLYN asked the Minister of Health whether there was any prospect of the Government, in continuation of the policy of giving assistance for the proper provision of water-supply in rural areas, contemplating the allocation of money towards sewerage and sewage disposal schemes under similar safeguards as were agreed in the case of water-supply, in order to assist rural district councils and county councils who now had power to contribute, but had not adequate funds to carry out thoroughly comprehensive schemes.—Sir KINGSLEY WOOD replied: No proposal on these lines is at present in contemplation.

#### Health Insurance and Ophthalmic Benefit

Mr. DAY asked the Minister of Health whether he would state the total amount spent by approved societies and branches on ophthalmic benefit, showing the amount separately that was spent on the provision of glasses for the two years ended to the last convenient date.—Sir KINGSLEY WOOD replied: The expenditure in England and Wales on ophthalmic benefit, which includes payment towards the provision of glasses as well as ophthalmic treatment, was £355,000 in the year 1934 and £360,000 in the year 1935. Separate figures are not available of the sums expended in the provision of glasses.

MONDAY, MAY 11TH

#### League and Nutrition Problems

Mr. MATHERS asked the Under-Secretary of State for India whether he was aware of the investigations by the League of Nations into problems of nutrition and the recommendation of the mixed committee that national committees should be set up to make national investigations; that the conference on rural hygiene in the Far East and the Congress of the Far Eastern Association of Tropical Medicine proposed in their next sessions to consider nutrition in Asia and the Far East; and whether he was taking steps to investigate the standard of nutrition of the Indian people and how to improve it.—Mr.

BUTLER replied: I am aware of the facts stated by the hon. Member in the first and second parts of the question. The question of nutrition is and has been for some years engaging the attention of the Government of India; and nutritional surveys in selected areas are now being carried out under the auspices of the Indian Research Fund Association, which is financed by the Government of India.

#### The Pollution of Water-supplies

Mr. SHORT asked the Minister of Agriculture (1) whether he was aware of the pollution of rivers by the waste water of sugar beet factories; whether the Water Pollution Research Board had discovered any simple and practical process by which these waste waters could be purified; and, if so, if he would call the attention of sugar beet factories to this fact, with a view to the discontinuance of such pollution; and (2) whether he was aware of the constant pollution of inland waterways by the effluents from dairies and factories manufacturing milk products; whether the Water Pollution Research Board had discovered processes by which these effluents could be purified, and, if so, whether he would call the attention of such factories to these processes in the interests of anglers and the preservation of cleanliness and the purity of our water-supplies.—Mr. ELLIOT replied: The Ministry has no powers in regard to the prevention and control of river pollution, which is a matter primarily for the local sanitation authorities or fishery boards. I am aware, however, that pollution does occur in some cases. As regards sugar beet, the Water Pollution Research Board advised in 1931 that the problem of pollution by sugar beet factories could be largely, and in many cases completely, solved by modifications in the factory processes and by simple methods of treatment of the waste waters so that the waters could be re-used in the factory. These conclusions were communicated to the industry, and I understand that a number of factories have taken effective steps to prevent pollution. The British Sugar Corporation, which will take over control of the beet sugar factories if Parliament approves the proposals in the Sugar Industry (Reorganisation) Bill, may be expected to give careful attention to this problem. As regards dairy and milk product factories, I understand that the Water Pollution Research Board has for some months been conducting experiments on effluent treatment with the financial co-operation of the industry. I have every hope that these experiments, with the progress of which the industry is being kept in close touch, will lead in the near future to useful practical results.

#### Milk (Special Designations) Order

Sir CECIL HANBURY asked the Minister of Health whether, in view of the wide differences in the way in which the Accredited Herd Scheme was being administered by the licensing authorities, he would issue instructions designed to secure uniformity in the administration of the new Milk (Special Designations) Order by county and county borough councils.—Mr. SHAKESPEARE replied: I would draw my hon. friend's attention to the answer given on this subject on April 30th. In the circular mentioned in that answer attention is drawn to the principles by which local authorities should be guided in granting licences.

TUESDAY, MAY 12TH

#### Standard of Overcrowding

Mr. JOEL asked the Minister of Health whether any complaints had been received from local authorities that the standard of overcrowding under the Housing Act of 1935 was too low; and, if so, if he would state the towns from which these complaints came.—Mr. SHAKESPEARE replied: My right hon. friend is aware that in some quarters the standard is regarded as low but, as my hon. friend knows, the standard is a penal standard and is therefore of necessity lower than, for example, the standard of accommodation adopted by local authorities for rehousing purposes. My right hon. friend is unable to trace any official representations from local authorities on the subject.

THE Home Secretary has appointed Dr. George Hugh Culverwell, O.B.E., D.P.H., to be an inspector for the purpose of the Cruelty to Animals Act, 1876.

## INTERNATIONAL CONGRESS OF PHYSICAL MEDICINE

At the opening session of this congress on May 12th, with Prof. I. GUNZBURG (Antwerp), president of the international committee of the congress, in the chair, Prof. W. T. ASTBURY (Leeds) spoke on

### New Ideas from X Ray Analysis of the Molecular Structure and Properties of Proteins

He said that proteins were generally considered to be extremely complex, and indeed were probably the basis of life itself. By means of X ray diffraction analysis some knowledge of their structure was being obtained. He hoped that in time their structure would be as well understood as that of, say, sodium chloride. According to the classical view, the proteins consisted of condensations of twenty or more amino acids, the peptide groups being joined one to another to form a long chain. The side chains were thought to determine the specific nature of the protein. This comparatively simple structure was found on X ray analysis to occur in the simplest fibres such as those of silk—where the long molecules lie extended along the fibres and give a characteristic X ray photograph. Another type of X ray picture was given by hair, wool, horn, whale bone, nails, and other keratinoid epidermal structures in their normal condition; but mathematical analyses of this picture showed that the chain of the molecule was folded. If, however, a hair was stretched the X ray picture characteristic of silk was obtained, and the molecules could again be shown to be straight. Presumably the remarkable elasticity of hair and other proteins depended therefore on the straightening and folding of the molecular structure. Normal hair could also be made to contract by various means such as by exposure to X rays and steam. This was known as super contraction and was of particular interest. Muscle-fibres at rest gave an X ray photo almost indistinguishable from that of normal hair; muscle protein could also be made to undergo stretching and super contraction. Most of the experimental work had been performed on dead material, but recent work on living tissue provided confirmatory evidence, and there was reason to believe that the super contraction of hair was analogous to the changes of contracting muscle. The remarkably long range of elasticity of many biological structures turned out then to be a property of the protein molecule itself, which was thus eminently fitted for the purposes of movement, growth, and enzymotic activity. Crystalline proteins such as pepsin and insulin were definitely globular and not arranged in long chains, but many such proteins could now be converted into the long chain form and made into fibres.

In the afternoon Sir ROBERT STANTON WOODS, president of the congress, took the chair and Lord DAWSON OF PENN spoke on

### Physical Education

The Golden Age of Greece, he said, stood forth in history with ideals of education which gave equal prominence to the training of body and mind for the production of whole men, both strong and beautiful, and it was a matter for wonderment that its bequest to all ages of a culture beyond compare should have faded away and lain dormant. It was only at the beginning of the nineteenth century that Denmark had led the modern world by making physical education an essential part of the curriculum in its national schools. Soon after, Ling persuaded the Swedish

Government to establish the Central Institute in Stockholm of which he was appointed director in 1813. From these beginnings physical education had extended to various countries, but was slow to gain foothold in Great Britain with its traditional love of games and sports. Not until 1909 was physical education established on the time-table of all elementary schools in this country. The next milestone, said Lord Dawson, was the "primitive gymnastics" movement in Denmark, founded by Niels Bukh. This was a revolt against the Ling system which had come to be regarded as formal, static, and sombre. With a basis of fundamental gymnastics Bukh used games and folk dancing to teach balance and grace of movement. Miss Margaret Morris, in this country, had thought along similar lines and secured like results. She regarded the training of lungs, abdomen, and feet as the first essential.

Although in practice often overlapping, physical education, games and sports, and recreational physical training served distinctive purposes. Physical education belonged to school hours and required a trained instructor; games were part of recreation and were directed mainly by the pupils. Proficiency in games was compatible and often existed with defects of frame or function. Such defects might be improved by physical education, the neglect of which might become a progressive handicap to the child. Some games, unless correlated with physical education, were liable to overstrain their votaries and impair health later in life. On the other hand, physical education could not replace sports and games. The rivalry of games, quickening the mind and body, the team spirit, the responsibility of leadership, and the joy of effort could not be derived from physical exercises; physical education therefore made use of games even in school hours whenever possible. This last idea found its expression in recreational physical training, which was valuable in giving health and fitness to those at work and especially to those between 14 and 18 years of age.

In Lord Dawson's view physical training was a growing necessity. In days past when life was less protected and there were no organised measures like insurance and social services, natural selection operated more effectively and the unfit were prone to be extinguished. With the growth of the human conscience the unfit were being preserved. Doubtless that was right, but it was the more necessary to build up the fit. We had therefore to look after nutrition and the training of the body as well as that of the mind for health and efficiency. Modern industrialism, the sedentary life imposed on many people, and specialisation necessitated the provision of opportunities for exercise of the body as a whole; these changes of social and economic life had come to stay. Lord Dawson quoted some examples of great improvement in physique brought about in short periods by physical education. There was now a strong effort being made in this country to save men from the weakening of physique apt to result from unemployment. An increase in training colleges for teachers was urgently needed. The women's training colleges in this country had for some years been ahead of those for men.

A teacher of physical education could with advantage also be trained in education of the mind. Such a combination secured a wider outlook, and further, a teacher equipped to educate the mind was still in the flowing tide of his career at an age when the teacher of physical education was on the ebb.

The doctor should collaborate in physical education and periodic surveys by him might assist detection of early divergencies from normal development. The movement towards a complete system of physical education was going on apace in this country and had been helped in no small measure by the investigation and report by the British Medical Association.

Sir LEONARD HILL, speaking on the

### Hygiene of Sport

said that skilled movement was the basis of man's mental equipment; yet some 70 per cent. of the

British youth between the ages of 14 and 18 did not participate adequately in physical training. The examination system was the means of promoting boys to universities without due consideration of their physique. It was not wise to spend millions on equipment for national defence and neglect the very basis of physical fitness. Sir Leonard spoke of the fine physique which was resulting from widespread physical training in Germany. In every part of London there should be flood-lit sports grounds and swimming baths, the former arranged not for holding competitive sport, but for the exercise of the citizens in their leisure hours.

## MEDICAL NEWS

### University of Oxford

Dr. B. D. Pullinger has been appointed university lecturer and demonstrator in pathology and Dr. S. Zuckerman university lecturer and demonstrator in human anatomy.

During the visit of the British Medical Association to Oxford in July, the honorary degree of D.Sc. will be conferred on Sir George Newman, Sir Cuthbert Wallace, P.R.C.S., Sir Henry Dale, F.R.S., Sir Walter Langdon-Brown, Dr. Robert Hutchison, and Prof. Charles Singer.

The next dean's dinner will be held in the Chantecler Restaurant, Frith-street, London, W., at 7.30 p.m. on Thursday, May 28th. Oxford medical students who wish to attend should communicate with the dean of the medical school at his office at the University Museum before May 25th.

### Royal College of Surgeons of England

At the recent primary examination for the fellowship the following candidates were successful:—

D. J. Anderson, Sydney; P. B. Banaji, St. Bart.'s and Middlesex; V. H. Barnett, Univ. Coll. and Middlesex; C. H. Bliss, St. Thos., St. Bart.'s, and Middlesex; G. W. Blomfield, Leeds, Univ. Coll. and Middlesex; A. F. Bryson, Camb., Lond., and Univ. Coll.; A. S. Bullough, Manch. and Middlesex; H. W. Burge, King's Coll.; R. C. F. Catterall, Camb., Univ. Coll. and Middlesex; L. Chanock, Aberd. and Edin.; R. Cox, Univ. Coll., King's Coll., and Westminster; S. K. Datta, Calcutta and Univ. Coll.; J. R. Dawson, Adelaide, Otago, Univ. Coll., and Middlesex; J. A. Dhacka, Bombay and Univ. Coll.; A. T. Doss, Cairo and Middlesex; D. M. Douglas, St. Andrews and Univ. Coll.; T. K. Elliott, St. Mary's; M. Fahmy, Cairo, Middlesex, and St. Bart.'s; C. M. Gardner, McGill, Univ. Coll., and Middlesex; D. W. C. Gawne, Camb. and St. Bart.'s; H. M. Goldberg, Univ. Coll.; J. C. Goligher, Edin. and Middlesex; J. H. Gould, St. Bart.'s and St. Thos.; K. I. Graham, Melbourne and Middlesex; Phyllis N. Green, Roy. Free; H. W. Hall, Univ. Coll.; R. A. Hall, Leeds; J. Hanekom, Cape Town and Middlesex; G. O. Jelly, Oxon and Guy's; C. D. P. Jones, Univ. Coll.; R. H. Karmarkar, Bombay, Univ. Coll., and Middlesex; F. R. Kilpatrick, Cape Town and Guy's; J. B. Kinmonth, St. Thos.; Dorothy M. S. Knott, Roy. Free; R. S. Lawrie, Middlesex; W. S. Lewin, Univ. Coll.; H. F. Lunn, Guy's; J. D. Macleod, Univ. Coll., St. Thos., and Middlesex; S. C. Mehta, Ahmedabad and Lond.; W. G. Q. Mills, Camb., St. Mary's and Middlesex; A. K. Monro, Camb. and Lond.; J. B. Morrow, Belfast and Middlesex; J. A. Moyses, Manitoba; R. S. Murley, St. Bart.'s; S. K. Nag, Calcutta and Univ. Coll.; C. D. Needham, Middlesex; G. E. Nevill, Dublin; J. Patrick, Edin. and Sheff.; G. H. Pearce, Univ. Coll.; A. Rafta, Cairo and King's Coll.; B. N. B. Rao, Bombay and Middlesex; G. C. D. Roberts, Camb., St. Thos., and Middlesex; H. J. Ross, Aberd., Middlesex, and Univ. Coll.; E. P. Row, Sydney and St. Mary's; T. R. Sarjeant, Toronto and Univ. Coll.; G. C. Sawyer, Guy's; J. C. Scott, Toronto and Oxon; W. N. Searle, Otago, Univ. Coll., and Middlesex; L. M. Snaith, Durham; K. W. Starr, Sydney and Univ. Coll.; A. S. Till, Camb. and Middlesex; W. H. D. Trubshaw, St. Bart.'s and Middlesex; A. J. Wilson, Camb. and St. Thos.; and M. M. Wilson, Camb. and Lond.

### Royal College of Physicians of Edinburgh

At a meeting of the College, held on May 5th, with Dr. W. T. Ritchie, the president, in the chair, Dr. Thomas Carlyle Mitchell (London) and Dr. John James Black Martin (Dorchester) were elected fellows. The Lister fellowship was awarded to Lieut.-Colonel W. F. Harvey, I.M.S.

### University of Sheffield

Mr. Glyn Davies, registrar at the Jessop Hospital for Women, has been appointed lecturer in obstetrics and gynaecology, and Dr. J. C. Paisley, junior assistant bacteriologist.

Sir Bruce Bruce-Porter has been appointed Deputy-Lieutenant for the County of London.

### West London Medico-Chirurgical Society

On Thursday, June 4th, at 8.30 p.m., Prof. William Wright will deliver the Cavendish lecture of this society at the Kensington Town Hall. He will speak on the Princes in the Tower. The annual conversazione and medical and surgical exhibition will follow the lecture.

### Lebanon Hospital for Mental Diseases

The thirty-seventh annual meeting of this hospital will be held at Friends House, Euston-road, London, N.W., on Monday, May 18th, at 3.15 p.m., when Sir Hubert Bond, senior commissioner of the Board of Control, will be in the chair. The speakers will include Dr. E. W. G. Masterman.

### A Medical Research Fellowship

Applications are invited by the council of the Royal Society for the E. Alan Johnston and Lawrence research fellowship, which is tenable in any hospital or medical school in the British Isles. The stipend is £700 a year and the appointment will be for two years in the first instance and may be renewed up to five years. Further information may be had from the assistant secretary of the society, Burlington House, London, W.

### Glasgow Post-Graduate Medical Association

A general medical and surgical course will be held by this association during the last two weeks of August and the first two weeks of September at the Western Infirmary, the Royal Infirmary, and the special hospitals of the city. A number of clinical assistantships will also be available to graduates who wish to make a detailed study of one of the specialties. Further information may be had from the secretary of the association, The University, Glasgow.

### Conference on Fever Therapy

As already announced, the first International Conference on Fever Therapy is to be held at Columbia University, New York, from Sept. 29th to Oct. 3rd, under the chairmanship of Baron Henri de Rothschild. The subjects to be discussed will include physiological and pathological changes in fever; and the use of fever therapy for gonorrhoea in the male and female, gonococcal and non-specific arthritis, syphilis in its various stages, neurological conditions, and skin diseases. Further information about the meeting may be had from Dr. William Bierman, 471, Park-avenue, New York, U.S.A.

### Socialist Medical Association

The sixth annual general meeting of this association is to be held at the Royal Hotel, Woburn-place, London, W.C.1, on Sunday, May 24th, commencing at 11 a.m., when the report of the executive committee will be presented and its recommendations for drastic alteration in the constitution of the association. Notice has been given of motions to approve the legalisation of voluntary sterilisation and the principle of voluntary euthanasia, and to discuss the attitude of the association to war. At 5 p.m. Col. A. H. Proctor, M.D., I.M.S. (retd.), dean of the British Postgraduate Medical School, will lecture on State Hospitals and Medical Education.

Dr. Peter McRitchie, a well-known medical practitioner in the Swansea district, died on the day of his son's funeral. The son, a student at Aberystwith College, had died in a sanatorium and on the morning chosen for his funeral his father died from heart failure in his sleep. Father and son were buried in the same grave.

#### Hospital Furniture Display

A special display of hospital furniture is being held on the ground floor of British Industries House. More than thirty firms which specialise in furniture and other domestic equipment for hospitals, such as chinaware and cutlery, are taking part, and the exhibition will be open until May 23rd.

#### The Synthesis of New Radio-active Elements

An address on this subject will be given by Prof. and Madame Joliot-Curie at the Wigmore Hall, Wigmore-street, London, W.1, on June 5th at 5 p.m., under the auspices of the Medical Association of the International Clinic. Lord Lytton will preside.

#### Medical Prayer Union

The annual medical missionary breakfast of this union will be held at the refectory, University College, Gower-street, London, W.C., on Wednesday, May 27th, at 8 a.m. The chair will be taken by Mr. W. McAdam Eccles, and an address will be given by Dr. Mary Watson, of the Church Missionary Society, South China. Those wishing to attend should notify the secretary, Dr. Tom Jays, at Livingstone College, Leyton, E.10.

#### Royal Society of Medicine

Applications are invited by this society for the Nichols fellowship which is offered for research relating to the discovery of the causes and the prevention of death in childbirth from septicemia. The fellowship is tenable for two years and applications should be sent to the secretary of the society, 1, Wimpole-street, W.1, not later than Oct. 1st.

#### East London Child Guidance Clinic

On Wednesday, May 27th, at 3 p.m., at Jews' Free School, Bell-lane, Bishopsgate, E., Prof. Alfred Adler will give a demonstration clinic on cases of child neurosis and behaviour disorder.

#### Brighton and Slum Clearance

At Brighton on April 8th Sir Kingsley Wood, the Minister of Health, opened a new health clinic, and homes for aged people and houses for dispossessed slum tenants on the Manor Farm estate. He said he had ample evidence that Brighton was determined to be in the forefront of the continued campaign for better health, better conditions, and particularly for better homes. Sir Herbert Carden, a member of the local corporation, said Brighton had had some of the filthiest slums in England, but the worst had disappeared, and in another year practically all of them would have vanished. Warm tributes were paid to the work of Dr. Duncan Forbes as medical officer of health.

#### Fellowship of Medicine and Post-Graduate Medical Association

Arrangements for June include a course in gynaecology at the Chelsea Hospital for Women (June 8th to 20th); and clinical and pathological demonstrations and lectures for M.R.C.P. candidates at the National Temperance Hospital on Tuesday and Thursday evenings at 8 p.m. (June 9th to 25th); and lectures on chest and heart diseases at the Victoria Park Hospital on Wednesday and Friday evenings at 6 p.m. (June 17th to July 10th); on chest diseases at the Brompton Hospital on two afternoons weekly at 5 p.m. (June 15th to July 11th); and an afternoon course on neurology and psychotherapy at the West End Hospital (June 8th to July 4th). Week-end courses in June will be given on general medicine at the Prince of Wales's Hospital (June 6th and 7th); in obstetrics at the City of London Maternity Hospital (June 13th and 14th); in fevers at the Park Hospital (June 20th and 21st); and in general surgery at the Prince of Wales's Hospital (June 27th and 28th). Courses are open only to members and associates of the Fellowship, and further information may be had from the secretary of the Fellowship, 1, Wimpole-street, London, W.1.

#### Chelsea Hospital for Women

In 1934 this institution had an excess of income over expenditure of £1804; but last year there was an excess of expenditure over income of £2226.

#### Crewe Memorial Hospital

Lady Somervell has opened the new women's ward at this hospital and named it the Jubilee ward. The hospital is about forty years old.

#### City of London Hospital for Diseases of the Chest

The overdraft of this hospital is £5373, and additional funds are needed for extensions which will include surgical wards.

#### West End Hospital for Nervous Diseases

At the annual general meeting of this institution, held on April 30th, it was stated that a deep X ray therapy apparatus, which would cost about £1200, was urgently needed.

#### Caterham Hospital

Sir Bernard Greenwell has given five acres of land for a new hospital at Caterham. The present hospital has served the district for more than sixty years but the limit of expansion on the present site has now been reached.

#### Royal Eye Hospital, Southwark

Earl Beatty presided at the annual meeting of this hospital when it was announced that the foundation-stone of the new building will not be laid until £80,000 has been raised towards the necessary £200,000. During 1935 28,820 new out-patients attended the hospital.

#### Durham County Hospital

All sections of the community have combined to support this hospital and it is in a stronger financial position than it has been for some years. The excess of income over expenditure last year was £3424, which went to reduce the deficit account to £10,768.

#### Medical Motorists

Under the auspices of the Union Internationale des Automobile-Clubs Médicaux a congress of medical motorists will be held in Paris from June 14th to 17th. The subjects to be considered include road accidents, assistance on the road, and the psychological examination of drivers. The president is Dr. G. A. Prins, of Utrecht, and the secretary-general may be addressed at 89, Boulevard Magenta, Paris X.

#### Royal Medical Benevolent Fund

At a recent meeting of the committee of this fund 14 new applicants were assisted and 25 grants were renewed to beneficiaries. In all £918 was voted. The following particulars of a few cases helped indicate the kind of work undertaken:

Widow aged 79, of M.D. who died in 1886 aged 36. Under the will of her husband the applicant received £144 per annum from a trust fund. Both the executors appointed to administer the trust have died and it no longer exists. A nephew made up the deficiency till September, 1935, when he was unable to continue. Since then friends and neighbours have given charitable help and the Freemasons a gift of £10 10s. Fund gave immediate help of £3 and a yearly allowance of £36. The applicant will apply for the old age pension of £26, thus making her total income £62.

L.R.C.P., aged 61, suffering from cancer of the rectum. His savings are exhausted. Fund made a grant of £40.

Widow aged 66, of L.R.C.P. who died 1933 aged 65, is in receipt of a small allowance from the parish council. Her son, who is a medical student, was unable to pay his examination fee and hospital work fees. Fund has paid the fees and the examination has been passed satisfactorily.

This is the centenary year of the fund and a special appeal is being made for new subscribers to raise the annual income by subscriptions and donations to £20,000. From the present income of £14,000 allowances of £40 and £26 are made to medical practitioners and their dependents respectively. The increased income would enable the committee to raise these allowances to £52 and £36. An appeal is also being made this year for special donations to create a fund from which larger grants can be voted to very urgent and distressing cases, and which may be used to help with the training of the widows and orphan sons and daughters of medical practitioners to enable them to be self-supporting. Cheques should be made payable to the hon. treasurer of the fund, 11, Chandos-street, London, W.1.

## Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

### SOCIETIES

- ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**  
**TUESDAY, May 19th.**  
*Special Meeting of Fellows, 5 P.M.* Nomination of Officers and Council for 1936-37. 5.30 P.M. Ballot for Election to the Fellowship.
- THURSDAY.**  
*Dermatology, 4 P.M.* Annual General Meeting. Dr. Svend Lomholt (Copenhagen): Alpha and Beta Rays in Skin Therapy. Dr. Ramel (Switzerland): Neuro-pathic Eczema.  
*Neurology, 8.30 P.M.* Annual General Meeting. Pathological Specimens of Neurological Interest will be Shown.
- FRIDAY.**  
*Disease in Children, 5 P.M.* (Cases at 4.30 P.M.) Annual General Meeting. Mr. Denis Browne: Congenital Deformities of Mechanical Origin.  
*Epidemiology and State Medicine, 8.30 P.M.* Annual General Meeting. Dr. E. W. Goodall: Fracastor as an Epidemiologist.  
*Physical Medicine, 5.45 P.M.* Annual General Meeting at the Wharnclyffe Rooms, Great Central Hotel, N.W.
- SATURDAY.**  
*Orthopaedics, Meeting at Nottingham, 12.45 P.M.* Demonstration of Clinical Cases and Inspection at Harlow Wood Orthopaedic Hospital.
- CHELSEA CLINICAL SOCIETY.**  
**TUESDAY, May 19th (8.30 P.M. Hotel Rembrandt, Thurloe-place, S.W.), Mr. C. Lambrinudi: Backache.**
- SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thornhaugh-street, W.C.**  
*Fever Hospital Medical Services Group.*  
**FRIDAY, May 22nd.—4 P.M., Dr. Robert Forbes: Medical-legal Problems in Hospital Practice.**
- ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, Manson House, 26, Portland-place, W.**  
**THURSDAY, May 21st.—8.15 P.M., Dr. N. Hamilton Fairley and Dr. Colin Ross: Intestinal Absorption in the Steatorrhœas. Prof. L. G. Parsons will also speak.**
- LECTURES ADDRESSES, DEMONSTRATIONS, &c.**
- ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W. 1**  
**TUESDAY, May 19th, and THURSDAY—5 P.M., Sir Bernard Spilbury: Doctrine of Inflammation. (Croonian lectures.)**
- UNIVERSITY OF LONDON.**  
**MONDAY, May 18th, and TUESDAY.—5.30 P.M.** (University College medical school, University-street, W.C.), Mr. H. M. Traquair: Perimetry.  
**THURSDAY.—5.15 P.M.** (University College Hospital medical school, University-street, W.C.), Prof. Charles Singer: The History of the Theory of Infection. 5.30 P.M. (University College, Gower-street, W.C.), Dr. Alfred Adler: Some Recent Developments in Individual Psychology.
- BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.**  
**MONDAY, May 18th.—2.15 P.M., Dr. Duncan White: Radiological Demonstration, 3.30 P.M., Mr. V. B. Green-Armytage: Sterility.**  
**TUESDAY.—2 P.M., Prof. E. H. Kettle, F.R.S.: Pathological Demonstration, 3 P.M., Dr. A. A. Miles: Aspects of Blood Culture.**  
**WEDNESDAY.—Noon, clinical and pathological conference (medical), 2.30 P.M., clinical and pathological conference (surgical).**  
**THURSDAY.—2.30 P.M., Sir Henry Gauvain: Surgical Tuberculosis, 3 P.M., Dr. R. A. Young: Non-tuberculous Pulmonary Diseases. Dr. Chassar Moir: Operative Obstetrics.**  
**FRIDAY.—2.15 P.M., Dr. A. A. Davis: Gynaecological Pathology.**  
 Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetric and gynaecological clinics or operations.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**  
**MONDAY, May 18th, to SATURDAY, May 23rd.—St. JOHN'S HOSPITAL, Lisle-street, W.C. Afternoon course in dermatology.—MAUDSLEY HOSPITAL, Denmark Hill, S.E. Afternoon course in psychological medicine.—St. PETER'S HOSPITAL, Henrietta-street, W.C. All-day advanced course in urology.—Courses are open only to members of the fellowship.**
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.**  
**WEDNESDAY, May 20th.—2 P.M., Dr. Wilfred Pearson: Indigestion in Older Children, 3 P.M., Dr. W. W. Payne: Deficiency Diseases.**  
 Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.
- UNIVERSITY OF BIRMINGHAM.**  
**TUESDAY, May 19th.—3.30 P.M. (Children's Hospital), Dr. J. M. Smellie: Gastro-interitis in Infancy.**

- WEDNESDAY and FRIDAY.—4 P.M. (Medical Lecture Theatre, Edmund-street Buildings), Dr. Walter Schiller: Ovarian Tumours. (Ingleby lectures.)**
- THURSDAY.—4 P.M. (Medical Faculty Buildings), Mr. Hartley, D.Sc.: The Standardisation of Immunological Reagents. (William Withering lecture.)**
- MANCHESTER ROYAL INFIRMARY.**  
**FRIDAY, May 22nd.—4.15 P.M., Dr. Norman Kletz: Demonstration of Medical Cases.**
- ST. MARY'S HOSPITALS, Whitworth-street West, Manchester.**  
**TUESDAY, May 19th.—4.15 P.M., Dr. Walter Schiller: Cancer of the Uterus. (Lloyd Roberts lecture.)**
- ANCOATS HOSPITAL, Manchester.**  
**THURSDAY, May 21st.—4.15 P.M., Dr. W. J. S. Reid: Psychopathology.**
- GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.**  
**WEDNESDAY, May 20th.—4.15 P.M. (Royal Infirmary), Dr. J. A. C. Macewen: Gastric Cases.**

## Vacancies

For further information refer to the advertisement columns

- Accrington, Victoria Hospital.—H.S. £150.**  
**All Saints' Hospital, Austral-street, West-square, S.E.—Res. H.S. At rate of £100-£150.**  
**Ashford Hospital, Kent.—Res. M.O. £150.**  
**Barnsley, Beckett Hospital and Dispensary.—Cas. O. and H.P. £250 and £200 respectively.**  
**Birmingham, Erdington House.—Asst. M.O. £650.**  
**Bolton Royal Infirmary.—H.P. £200. Also two H.S.'s. Each £125.**  
**Bolton, Townleys Hospital, Farnworth.—Asst. M.O. £225.**  
**Bradford Royal Infirmary.—H.P. At rate of £135.**  
**Brighton, New Sussex Hospital for Women, Windlesham-road.—H.P. and H.S. Each £100.**  
**Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.**  
**Burton-on-Trent, Brelby Hall Orthopaedic Hospital.—Locum Res. Asst. M.O. At rate of £350.**  
**Burton-on-Trent General Infirmary.—H.P. and Cas. O. £150.**  
**Cambridge, Addenbrooke's Hospital.—Res. Surg. O. £225.**  
**Cardiff, Llandough Hospital.—Jun. Res. M.O. At rate of £100.**  
**Cardiff Royal Infirmary.—Gynaecological H.S. At rate of £50.**  
**Charing Cross Hospital, Strand, W.C.—Part-time Med. Reg. At rate of £50.**  
**Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100.**  
**City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Surg. and Med. Regs. £225 and £175 respectively. Also H.P. At rate of £100.**  
**Coventry, Gulsom-road Municipal Hospital.—Second Asst. Res. M.O. £250.**  
**Coventry and Warwickshire Hospital.—Hon. Ophth. Surgeon. Also Res. H.S. £125.**  
**Delamere, Cheshire, Crossley Sanatorium.—Med. Supt. £650.**  
**Derbyshire County Council.—Asst. Maternity and Child Welfare M.O. £600.**  
**Doncaster Royal Infirmary.—H.S. £175.**  
**Dreadnought Hospital, Greenwich, S.E.—Receiving Room Officer. At rate of £200.**  
**Durham County Council Education Department.—Asst. School M.O. £500.**  
**Ealing, King Edward Memorial Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £200 and £150 respectively.**  
**East Ham Memorial Hospital, Shrewsbury-road, E.—H.S. to Spec. Depts. and Cas. O. At rate of £120.**  
**East Lophian Sanatorium.—Second Jun. Res. M.O. At rate of £175.**  
**Evelina Hospital for Sick Children, Southwark-street, S.E.—H.P. At rate of £120.**  
**Exeter, Devon Mental Hospital, Exminster.—Jun. Asst. M.O. £350.**  
**Hackney Metropolitan Borough Council.—Public Vaccinator.**  
**Halifax Royal Infirmary.—Third H.S. At rate of £150.**  
**Hartlepool Hospital.—Second H.S. At rate of £150.**  
**Herefordshire County Council.—Asst. M.O. £500.**  
**Holt, Norfolk, Kelling Sanatorium.—Second Asst. Res. M.O. £350.**  
**Hospital for Sick Children, Great Ormond-street, W.C.—Res. H.P. and Res. H.S. Each at rate of £100.**  
**Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.**  
**Huddersfield Royal Infirmary.—Res. Surg. O. £225-250. Also H.S., H.P., and Res. Anaesthetist. Each at rate of £150.**  
**Hull Royal Infirmary.—H.S. to Ophth. and Ear, Nose, and Throat Dept. At rate of £150. Also H.S. to Sutton Branch Hospital. At rate of £160.**  
**Ipswich, East Suffolk and Ipswich Hospital.—H.S. £144.**  
**Isleworth, West Middlesex County Hospital.—Asst. M.O. £400.**  
**Kidderminster and District General Hospital.—H.S. £150.**  
**Lancashire County Council.—Asst. County M.O.'s. Each £800.**  
**Leicester City.—Asst. School M.O. £500.**  
**Leicester City Mental Hospital, Humberstone.—Third Asst. Res. M.O. £350.**  
**Lincoln, Burton-road Hospital.—Asst. M.O.H. £600.**  
**Liverpool City.—Asst. Venereal Diseases M.O. £400.**  
**Liverpool Hahnemann Hospital.—Hon. Asst. Ophth. S.**  
**Liverpool University.—Lecturer in Physiology. £600-£700. Also two Demonstrators. Each £300.**  
**Llanely and District Hospital.—H.S. £150.**  
**London County Council.—Asst. M.O.'s. Each £470. Asst. M.O., Grade I. £350. Asst. M.O.'s, Grade II. Each £250. H.P. At rate of £120. Temp. Asst. M.O., Grade I. At rate of £350. Visiting M.O. £200. Also Temp. Dist. M.O. At rate of £150.**

*London Hospital, E.*—Hon. Asst. Surgeon to Ear, Nose, and Throat Dept.  
*Manchester, Ancoats Hospital.*—H.S. At rate of £100.  
*Manchester and Salford Hospital for Skin Diseases.*—Two Asst. M.O.'s. Each £100.  
*Manchester Royal Children's Hospital, Pendlebury.*—Res. Surg. O. At rate of £125. Also Res. H.S. At rate of £100.  
*Manchester, Withington Hospital and Institution.*—Asst. M.O. (Grade 2), 2 Asst. M.O.'s (Grade 3). At rate of £250 and £200 respectively.  
*Middlesex Hospital, W.*—Part-time Dental Registrar. At rate of £150.  
*Miller General Hospital, Greenwich-road, S.E.*—Res. Surg. O. and Reg. £250. Cas. O. At rate of £150. Also two H.P.'s and H.S. Each at rate of £100.  
*Mount Vernon Hospital, Northwood.*—H.S. At rate of £150.  
*Newcastle-upon-Tyne Hospital for Sick Children.*—Asst. Hon. Physician to Skin Dept.  
*Newcastle-upon-Tyne, Royal Victoria Infirmary.*—Jun. Surg. Reg. £150.  
*Norwich, Norfolk and Norwich Hospital.*—Cas. O. Also H.S. to Spec. Depts. Each £120.  
*Nottingham Children's Hospital.*—Res. H.P. At rate of £150.  
*Nottingham General Hospital.*—H.S. At rate of £150.  
*Nottingham General Hospital, Gregory Boulevard Branch.*—Res. Surgeon. £250.  
*Oldham, Boundary Park Municipal Hospital.*—Res. M.O. £350.  
*Oxford, The Warneford.*—Jun. Asst. M.O. £350.  
*Plymouth, Prince of Wales's Hospital, Greenbank-road.*—Res. Surg. O. At rate of £225. Also H.S., Res. Anaesthetist, and H.S. to Spec. Depts. Each at rate of £120.  
*Poplar Hospital for Accidents, East India Dock-road, E.*—Second Res. Officer. £175.  
*Princess Beatrice Hospital, Earl's Court, S.W.*—Res. M.O. At rate of £150. Also Hon. Asst. Surgeon to Ear, Nose, and Throat Dept.  
*Queen's Hospital for Children, Hackney-road, E.*—Psychiatrist.  
*Queen Mary's Hospital for the East End, Stratford, E.*—Hon. Asst. Surgeon, Res. M.O., and two Cas. and Out-patient Officers. Each at rate of £150. Also H.P.'s, H.S.'s, and Res. Anaesthetist. Each at rate of £120.  
*Radium Beam Therapy Research, &c., 16, Riding House-street, W.*—Asst. M.O. At rate of £250.  
*Royal Cancer Hospital, Fulham-road, S.W.*—H.S. At rate of £100.  
*Royal Free Hospital and London (R.F.H.) School of Medicine for Women, W.C.*—Res. Asst. Pathologist. At rate of £150.  
*Royal Naval Medical Service.*—M.O.'s.  
*Royal Northern Hospital, Holloway, N.*—Hon. Radiologist.  
*Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.*—H.S. At rate of £100.  
*Royal Westminster Ophthalmic Hospital, Broad-street, Holborn, W.C.*—Cruise Clin. Res. Scholarship. £100.  
*St. Mary's Hospital, W.*—Jun. Asst. Radiologist. £75.  
*Salvation Army Mothers' Hospital, Lower Clapton-road, E.*—Jun. Res. M.O. At rate of £80.  
*Seamen's Hospital Society, Greenwich.*—H.S. for Tilbury Hospital. At rate of £140.  
*Sheffield, Jessop Hospital for Women.*—Res. M.O. Also H.S. At rate of £150 and £100.  
*Sheffield Royal Infirmary.*—Ophth. H.S. At rate of £120.  
*Sheffield University.*—Demonstrator in Anatomy. £300.  
*Smethwick County Borough.*—Asst. M.O.H. and Asst. School M.O. £350.  
*South Eastern Hospital for Children, Sydenham, S.E.*—Hon. Cons. Surgeon. Also Jun. Res. M.O. At rate of £100.  
*South London Hospital for Women, Clapham Common, S.W.*—H.P. and two H.S.'s. Each at rate of £100.  
*Stoke-on-Trent, North Staffordshire Royal Infirmary.*—H.S. £150.  
*Taunton and Somerset Hospital.*—Sen. House M.O. At rate of £150.  
*University of London, King's College, Strand, W.C.*—Asst. Lecturer and Research Worker. £300.  
*Walsall County Borough.*—Asst. M.O.H. £350.  
*West Bromwich, Hallam Hospital.*—Two H.P.'s and H.S. Each at rate of £200.  
*West London Hospital, Hammersmith-road, W.*—Res. Asst. Surgeon. £200. Also Res. Anaesthetist. At rate of £100.  
*West Malling, Kent, Leybourne Grange Colony for Mental Defectives.*—Asst. Res. M.O. £350.  
*Wickford, Esser, Runwell Hospital.*—H.P. At rate of £150.  
*Wilkesden General Hospital, Harlesden-road, N.W.*—Hon. Clin. Assts. for Out-patients' Dept.  
*Winchester, Royal Hampshire County Hospital.*—H.S. At rate of £125.  
*Windsor, King Edward VII. Hospital.*—Cas. H.S. At rate of £100.  
*Woking and District Victoria Hospital.*—Res. M.O. At rate of £120.  
*Wolverhampton Royal Hospital.*—H.P. Also H.S. At rate of £125 and £100 respectively.  
*Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.*—Hon. Asst. Obstet. Surgeon. Also two H.S.'s. Each at rate of £100.  
*Worksop, Victoria Hospital.*—Sen. and Jun. Residents. £150 and £120 respectively.  
*Zelland County.*—County M.O.H. £700.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Bromyard (Hereford) and Exeter (Devon).

## Appointments

APPLEBEE, MOYA, M.B. Belf., D.P.H., has been appointed Hon. Assistant Physician to the Devonshire Royal Hospital, Buxton.

BATTEN, GRACE, B.M. Oxon., D.M.R.E., Research Assistant to the William Morris Research Fellow at Mount Vernon Hospital.  
 BELL, A. C. H., M.B. Lond., F.R.C.S. Eng., Hon. Gynecologist to the Edenbridge and District War Memorial Hospital.  
 BROWN, BESSIE, M.D. Leeds, Resident Surgical Officer at the Leeds Maternity Hospital.  
 EWING, J. B., M.D., F.R.C.S. Edin., Resident Medical and Surgical Officer and Registrar at Wigan Infirmary.  
 GATES, E. A., M.D., M.R.C.P. Lond., Hon. Physician to the Italian Hospital, London.  
 GOODGER, JOAN, M.R.C.S. Eng., D.P.H., Assistant Medical Officer for Kensington.  
 GREEN-ARMITAGE, V. B., M.D. Brist., F.R.C.P. Lond., Hon. Gynecologist to the Italian Hospital, London.  
 HOWARD, STANFORD, B.M. Oxon., F.R.C.S. Eng., Hon. Assistant Surgeon to the Poplar Hospital for Accidents.  
 KEDDIE, J. T. C., M.B. Manch., D.P.H., Medical Officer of Health for Oldham.  
 LYNCH, C. F., M.B. Belf., D.P.H., Assistant Medical Officer of Health for Manchester.  
 MARINKOVITCH, R., M.D. Leeds, Venereal Diseases Medical Officer for Salford.  
 PETHER, G. C., M.D., M.R.C.P. Lond., Hon. Assistant Physician to the Devonshire Royal Hospital, Buxton.  
 REID, ANNA M. M., M.B. Edin., D.P.H., Assistant County Medical Officer for the County of Northumberland.  
 SIMPSON, W., M.D. Glasg., First Assistant Medical Officer at Barnsley Municipal General Hospital.  
 SPINK, M. S., M.D. Camb., Resident Medical Officer at the City General Hospital, Leicester.  
 WEBSTER, R. C., M.B. Irel., Assistant Medical Officer at the Venereal Diseases Treatment Centre, Salford.  
 King Edward VII. Welsh National Memorial Association.—The following appointments are announced:—  
 THOMAS, D. M. E., M.R.C.S. Eng., Assistant Tuberculosis Medical Officer;  
 MEWTON, J. L., M.B. Liverp., F.R.C.S. Edin., Resident Medical Officer;  
 MORRIS, G. J., M.R.C.S., Assistant Resident Medical Officer.  
 Certifying Surgeon under the Factory and Workshop Acts: Dr. D. C. PIM, M.C. (Calvert District, Bucks).  
 Medical Referee under the Workmen's Compensation Act, 1925: T. L. CLARK, M.D., F.R.C.S., of Halifax, for the Halifax County Court District (Circuit No. 12).

## Births, Marriages, and Deaths

### BIRTHS

BARBOR.—On May 7th, the wife of Dr. Ronald Barbor, of Hoddesdon, Herts, of a son.  
 BROMLEY.—On May 2nd, at Bury St. Edmunds, the wife of James Wilfred Bromley, M.B. Camb., of a daughter.  
 CAMERON.—On May 3rd, at a nursing-home, Aberdeen, the wife of Dr. T. W. F. Cameron, of Chatham, of a son.  
 GOSSIP.—On May 4th, at Sutherland-avenue, W., the wife of Dr. James Gossip, of Warwick-avenue, W., of a daughter.  
 HOPE.—On May 4th, the wife of Dr. J. P. Hope, Sheffield, of a son.  
 PIMBLETT.—On May 2nd, at a nursing-home, Lincoln, the wife of Flight-Lieut. H. C. S. Pimblett, M.D., R.A.F., of a son.  
 POST.—On May 3rd, at Devonshire-place, the wife of Dr. H. W. A. Post, of a daughter.  
 SIMPSON.—On May 4th, at Kensington Park-road, W., the wife of Reginald Hugh Simpson, M.D., F.R.C.P. Lond., of a son.

### MARRIAGES

MCPHERSON—SUTHERLAND.—On April 30th, Alexander Roberts McPherson, M.B. Edin., to Agnes Sutherland of Gilwern, Abergavenny.  
 TYRRELL—STENNING.—On April 25th, at St. Andrew's Church, Holborn, Timothy Martin Tyrrell, F.R.C.S. Eng., to Beryl Mary Gwendoline, daughter of Mr. A. E. Stenning of Philbeach-gardens, S.W.

### DEATHS

COHEN.—On May 4th, at the London Hospital, Dr. Alan E. Cohen, youngest son of Mr. M. E. Cohen, Didsbury, Manchester.  
 COOKE.—On May 4th, at Woodlands, Wootton, I.W., Reginald T. Cooke, M.R.C.S. Eng., aged 60.  
 FRASER.—On May 11th, at Melville-street, Edinburgh, John Smith Fraser, M.B., F.R.C.S. Edin.  
 HAINES.—On April 15th, at Longford, Tasmania, Hugh G. Haines, F.R.C.S. Edin., son of the late Lieut.-Colonel Gregory Haines and the Hon. Mrs. Haines, aged 82.  
 LEICESTER.—On May 3rd, George Frederick Leicester, M.B. Edin., of Castlemain-avenue, Bournemouth.  
 LINEHAN.—On April 12th, 1936 (Easter Sunday), at a private nursing-home, Dublin, Bridget Linehan, M.B. N.U.I., D.P.M. R.C.S.I., late A.M.O. County Mental Hospital, Lancaster, and Millstreet, Co. Cork, Ireland, R.I.P.  
 SHAW.—On May 9th, at his home, Littlehampton, Harold Batty Shaw, M.D., F.R.C.P. Lond., F.R.C.S. Eng., late physician to University College Hospital, London.  
 SLADE.—On May 3rd, at a nursing-home in London, John Godfrey Slade, M.D. Camb., aged 59.  
 WYLLYS.—On May 11th, at Great Yarmouth, Henry John Mackesou Wyllys, F.R.C.S. Edin.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## NOTES, COMMENTS, AND ABSTRACTS

## PHARMACY JARS

By C. J. S. THOMPSON, M.B.E.

HON. CURATOR, HISTORICAL COLLECTION OF MUSEUM, ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE study of the pottery used in pharmacies in various European countries, from the Middle Ages to the eighteenth century, is one of considerable interest to those engaged in the practice of medicine. Many of the specimens still existing are very valuable not only for their artistic beauty but also for their inscribed labels which throw a light on the history of medication. Dioscorides (A.D. 40-90) is the first to tell us something about the storage of drugs in the early Christian era. He says that "for liquid medicines containers of silver, glass or horn should be used, also of earthenware that is not porous," and we still have numerous specimens of the clay vessels employed for the purpose in Greek and Roman times.

But the beauty and interest of the vessels used in pharmacy really dates from the introduction of enamelled pottery into Europe after the invasion of Spain by the Moors. The oldest centre for making Moorish faience was at Malaga, when as early as 1350 it is recorded that "its beautiful golden pottery was exported to the most distant countries." This Hispano-moresque pottery is a distinct class and is decorated with Moorish designs painted in metallic lustre produced by means of copper. The Italians adopted the brilliant prismatic hues of the Moors whose pottery excited their admiration, and soon they produced results which surpassed those achieved

by their instructors. The industry spread to Majorca, and Majolica, the ancient Tuscan name for the island, became the general designation for the early Italian pottery.

It is impossible in the space of a short article to give more than an outline of the development of Italian majolica between the fourteenth and the eighteenth centuries, or an indication of its great artistic beauty and importance; but the chief shapes of the vessels used for drugs and their preparations can be indicated. The commonest shape of the jars used for solids is the albarello. It is cylindrical in form with slightly concave sides, and varies in height from four to sixteen inches. The tops in early times were covered with bladder or parchment and, before labels were employed, were distinguished by armorial designs or strips of metal bearing the name of the contents, attached by a wire. For liquids, the ewer was used with a spout for pouring and a handle. The tops were covered in the same way until metal lids came to be employed.

Even before glaze was used, there was a pottery where pharmacy jars were fashioned at Oviedo in the fourteenth century and another at Pesaro is recorded in 1300. What is called the first period of Majolica began before 1500, when Faenza became famous for its productions. Dated specimens are known from 1500, and two fine examples, here reproduced from the collection of Sir StClair Thomson, are worthy of note for their characteristic decoration. One is painted with the portrait of a man wearing a crown and is inscribed "Villa Nova," while the other bears the head of a woman in profile. Two specimens of Castel Durante in the collection are dated 1569. They are remarkable for their fine

## PHARMACY JARS FROM THE COLLECTION OF SIR STCLAIR THOMSON

1 and 4. A pair of Faenza drug jars. XVI. century.  
2 and 3. A pair of Castel Durante in polychrome. Dated 1569. Label Lead Ointment.

## EWERS AND JARS FROM THE SAME COLLECTION

5. Pharmacy Ewer. Castelli. XVII. century. Label Oxymel of Squills.
6. Drug Jar. English Delft. XVII. century. Label Pill Mastic.
7. Pharmacy Ewer with stopper. Urbino. XVI. century.
8. Drug Jar. English Delft. XVII. century. Label Pill Rhubarb.
9. Pharmacy Ewer. Castelli. XVII. century. Label Syrup of Ground Ivy.

decoration in polychrome: green, blue, and yellow.

What may be termed the second period of majolica dates from about 1500, when the famous pottery of Urbino was founded. For colour and artistic beauty the pharmacy jars of Urbino are unsurpassed. Great artists such as Battista Franco and Raffaele del Colle were employed to carry out the designs in which figures, armorini, and landscapes formed part in brilliant colouring, a rich yellow, blue, and green being predominant. A famous set of pharmacy jars were made at Urbino to the order of the Duke of Guidobaldo for the pharmacy attached to his palace, which had the distinction of being the costliest pharmacy vases in the world. It is said that Queen Christina of Sweden, offered for them their weight in gold, as did also Louis XIV. The Grand Duke of Florence wanted to exchange them for silver vases of equal size, but Guidobaldo would not be tempted to part with them. On his death his heir presented them to the shrine of Our Lady at Loreto. Sir StClair has a beautiful example of Urbino in his collection. It is a pharmacy ewer painted with scenes and figures, carried out in brilliant colouring, and is specially interesting on account of having the original wooden stopper for insertion in the spout.

In the sixteenth century many other cities in Italy became famous for their pottery, most of which may be recognised from their distinctive designs and colourings. Among those celebrated was Castel Durante which dates from 1361. Its characteristic decoration consists of coats of arms, armorini and garlands, or patterns of a geometrical type, trophies, grotesques and medallions, many of which were the work of Sebastian di Marforio. Another early pottery was that of Deruta, which was famous for its yellow lustre edged with blue, and equally beautiful were the products of Gubbio, mainly the work of Maestro Georgio, which was noted for its peculiar ruby lustre and later for its shades of blue. Sienna must also be mentioned with its characteristic colourings of dark blue, brown, and black, and pharmacy jars from its pottery are extant dating from 1501.

Other famous potteries were carried on at Caffagiola which belonged to the Medici princes, Venice,

Florence, Treviso, Montelupo, and Castelli, the last named being remarkable for its beautifully executed landscapes and figures, some fine examples of which are in Sir StClair's collection. Caltagirone, the capital of Sicilian majolica, with its florid rich colouring of blended reds, blues, and yellows, is easily recognisable, as also the pottery of Savona notable for its varied shades of blue and artistic decoration. For the purpose of study and comparison many beautiful specimens of Italian majolica may be seen in the British and Victoria and Albert Museums, and also in the Wallace Collection at Hertford House.

In Sir StClair's collection are also many fine examples of pharmacy jars of Dutch and London Delft which it is not the object of this article to describe.

## TIMELY ISSUE OF GADD'S SYNOPSIS

THE issue of the thirteenth edition of Gadd's Synopsis of the British Pharmacopœia, 1932 (London: Baillière, Tindall and Cox, pp. 200, 3s.), coincides with the appearance of the new Poisons List and Rules, and the opportunity has been taken of incorporating a synopsis of them. In the table of chemicals, drugs, and preparations of the B.P., 1932, the statutory poisons are assigned to their respective parts of the Poisons List and Schedule 1 poisons are indicated. A note is also made of drugs and preparations, falling within Schedule 4, which can be supplied on prescription only. This table provides a ready means of reference to all official substances and preparations. The utmost care has been taken in its compilation, and it is remarkably free from typographical errors. Fifty-four pages are devoted to a summary of the Poisons Laws and the Dangerous Drugs Act and Regulations. This could be improved by the insertion of such common names as novocain, benzocain, &c., as examples of substances of the aminobenzoic ester series, synthalin as typifying the guanidines, and so forth. A few minor errors are noticeable; phenetidylphenacetin is spelt wrong on p. 154. The synopsis presents a concise account of the subject and should prove valuable to practitioners who wish to discover their obligations under these Acts and Rules.

### "LACK OF HINGHAM"—A COUNTRY PRACTITIONER OF VICTORIAN DAYS

THE death of Dr. Thomas Lambert Lack, a widely known Norfolk practitioner, which occurred recently in his ninety-fourth year, suggests to one who knew him, and knew intimately all the district where he worked, a retrospect; the way in which a country practice in a sparsely populated county was conducted between early Victorian days and the end of the nineteenth century was well illustrated by the life of this nonagenarian. "I remember," writes our correspondent, "the daily routine of the country doctor's life from the 'seventies onwards, that is, not only before the coming of motor-driven vehicles, but before many of the fundamental discoveries in medicine of the last century, and before the general revision of local government, which set a pattern to country practice; and this in its turn has been fundamentally changed from the old shape by the coming of motor traffic.

"Lack of Hingham"—in Norfolk always so styled—was an excellent exponent of the country practice of his time. He was born in Norfolk in the little town of Swaffham, and received his early education at the local grammar school. He became a student at King's College Hospital and qualified some 70 years ago, in accordance with universal practice, as M.R.C.S. Eng., L.S.A. After the usual period as an assistant he moved to the neighbouring town of Hingham, and for over 60 years carried on there a large general practice. He was a sound doctor, the part-time medical officer of health of the district, and general adviser on sanitation of the neighbourhood, and became, which must have been useful to the community, a justice of the peace for the county. My own father, who was 30 years Lack's senior, was also a country practitioner in the vicinity, and the daily round was similar in each case. Norfolk, still a typically agricultural country, was more strictly so 70 years ago, and the medical man had a very hard and responsible life in dividing up the 16 hours or so of his working day between parish and club work and the claims of a private practice. A successful practitioner like Lack had an assistant resident in the house or the surgery-dispensary adjoining, and his day ran like this. He rose early and the first part of the morning would be occupied in supervising or helping his assistant in dispensing. Then morning work in the surgery would cover the range of an out-patient casualty department. There was treatment of minor ills, injuries and ambulatory cases generally, diagnosis of medical cases, with a sharp eye for infectious disorders, and there would be frequent tooth extraction. Much of the details fell upon the assistant, and assistants themselves were divided into two classes, though their intent may have been to belong to the first class only. All were serving by apprenticeship the first period of their medical curriculum; while learning to dispense and conduct minor surgery they obtained from their principal a knowledge of anatomy, physiology, and therapeutics, and the elements of book-keeping. Some of them went on to a medical school and became duly qualified; others remained as unqualified assistants, finding the range of knowledge which they were able to acquire commanded a satisfactory payment while they served under qualified men. In the period of which I write many of these men were doing valuable work and filling a definite place in the pattern of practice, but abuses followed which need not be detailed and which ended in the abolition of the unqualified assistant.

As soon after 10 as duties in the surgery allowed, the doctor would be in the saddle or the gig, making rounds, visiting private homes, and, where the practice was extensive, calling at local centres either for messages or to deposit medicines for distribution in the villages. Luncheon or midday dinner the doctor obtained at the hour when the round was finished, rather than at any specified time; after which, in the afternoon, the proceedings of the

morning were repeated through another area of the practice. The end of the second round was the fluctuating time for the evening meal, and then there remained for the doctor, with the help of his assistant, to make a record of visits paid and cases to be noted, to write up his books, and to arrange the programme for the next day. Also some of the medicines which had been found necessary during the rounds had to be dispensed, and these were great days for the pill, potion, and plaster. Norfolk was sparsely populated and serious cases, medical or surgical, among rich or poor, had for the most part to be treated in their own homes. Only in exceptional instances could resort be had to a hospital and the methods of transport were exceedingly difficult, while their arrangement fell upon the doctor. No emphasis need be laid on the difference of the responsibilities of those days and the situations that arise since the arrival of motor traffic and the multiplication of cottage hospitals. But the doctor had more leisure than such a day as I have described would seem to offer. It is true that often he took no regular holiday, and certainly did not conceive the idea of being, through a period of weeks, away from his practice save on account of illness. But breaks would occur in the drudgery, society was more informal, and the doctor had many chances of indulging a love of sport. Many supported the local cricket-club, to some there fell the chance of a day with the hounds, while many country doctors shot over a large area with the land-owners and farmers of the neighbourhood. Lack was a keen and good shot and pursued his favourite sport when chance offered until late in life.

Our correspondent's picture has been drawn before, but it will bear the repetition. The class to which Lack belonged and which indeed he ornamented, is gone, but such a man's life-work was based on the same qualities which his analogue to-day, with his high equipment and advanced methods of transport, brings to bear in the conduct of practice.

### HOSPITAL LIBRARIANS

LESS than three years ago the librarians voluntarily engaged in distributing books to patients in English hospitals decided that it was necessary for the advancement of their work to form themselves into a Guild. The organisation attracted attention in foreign countries with the result that the membership includes a number of nationalities. France has recently formed a National Hospital Library Committee under whose auspices the second annual meeting of the Guild was held in Paris during the week-end from May 9th-11th.

The Duc de Broglie, as president of the French committee, supported by General Weygand, greeted the gathering at the opening session on Saturday when Dr. René Sand presented the annual report and welcomed the Guild as an accession to the social services connected with hospitals which have developed since the war. After a discussion upon the recruitment and training of hospital librarians opened by Mrs. Roberts, the honorary secretary of the Guild, M. Henriot, the inspector of the municipal libraries in Paris, gave an account of the collaboration of the library organisation with the public assistance authorities in establishing this service. The hospitals are supplied from one centre. The only exception is the new Hôpital Beaujon which has its own library provided with the assistance of a generous bequest. In the afternoon the visitors had an opportunity to see the fine new building which is described as a Gallicised adaptation of American hospital architecture. Among the special features in the care of the patients which especially demonstrate thoughtful consideration are the entirely separate admission of night emergencies so as not to disturb other patients and the allocation of a separate ward to mothers, whose babies are stillborn, whereby they do not have a reminder of their disappointment through association with mothers with babies. On Sunday morning Madame Getting, the president of the hospital social service, welcomed the visitors at the

Hôpital de la Pitié which contains the central library for many hospitals on the analogy of other necessities such as food-supplies which are distributed from a centre. Madame Houel, who acted as honorary secretary of the conference and has the direction of the distribution of the books, explained the arrangements made, through a committee who read all the books, for providing for the various requirements according to sex or the nature of their illness. The features of the organisation are that it is under the direction of a professional librarian, and that the library has been established with new books instead of being dependent upon the goodwill of donors of secondhand books as is usually the case in England.

Mr. C. E. A. Bedwell, chairman of the English Guild, opened the proceedings on Monday morning under the chairmanship of M. Chenevier, secretary-general of the Public Assistance, with a description of the relations in England between the hospital and library authorities. Voluntary hospitals as well as municipal hospitals, especially in London, are supplied by the voluntary organisation of the Red Cross, while some municipal libraries are supplying voluntary hospitals as well as municipal hospitals. The conference also considered the development of the Guild. It decided to enlarge the international council and to encourage the formation of national committees to be welded into an international federation.

The English visitors were particularly impressed by, and grateful for, the cordiality of their welcome. The whole gathering was a great encouragement to those who believe that books and the reading of them, if adequately organised, can make a real contribution to the progress of patients in general and mental hospitals. Much interest was shown in the *Book Trolley*, the quarterly organ of the Guild as well as a pamphlet, "How to Run a Hospital Library," which are both published from the headquarters of the British Red Cross Library at 48, Queen's-gardens, London. It remains only for the hospital and library authorities, encouraged by the members of the medical profession who appreciate the value of this work for their patients, to give such support to the Guild that it may be enabled to maintain the reputation of English hospitals in this branch of hospital activity.

#### INVALID CHILDREN'S AID ASSOCIATION

At the annual meeting of this association, held in London on Tuesday, with the Archbishop of Westminster in the chair, Sir Maurice Cassidy said that some 12,000 people in this country died every year from rheumatic heart disease—a disease which he believed would, before very long, prove to be preventable. The majority of those who died had been cardiac cripples for many years, and a large number died in childhood. In 1934 there had been more than 2000 children in special schools of the London County Council suffering from heart disease, and something like two-thirds of all victims of acute rheumatism died before the age of 50. Any scheme for tackling the rheumatic problem should have certain features: (1) rheumatism should be made notifiable; (2) research into the factors aggravating and predisposing to it should be encouraged; (3) treatment should be secured for all children suffering from the disease. It was vital that such children should be put to rest for at least three months under ideal hygienic conditions, this treatment to be followed by a long period of convalescence. The I.C.A.A. had special homes for children in both stages.

Sir Kingsley Wood spoke of the importance of environment. The good work done in a home or hospital was often largely undone if a child had to go back to overcrowded or unhealthy living conditions. As Minister of Health he appreciated all that municipalities were doing in the field of public health, but he could not overlook the great pioneer work of voluntary associations.

A resolution, pledging those present to obtain the necessary financial support for the work of the association, was formally proposed by Dr. J. Fawcett and seconded by Miss Helen Simpson. She had

referred to THE LANCET of 1828, and compared the torture meted out to Lord Byron in the unsuccessful attempt to cure him of crippledness in childhood with the skilled and kindly treatment available for the poorest man's child to-day. The I.C.A.A. was constantly interfering with the course of history by changing the outlook of crippled children. Many were cured, and those who could not be cured were helped to get work they could do. Miss Yvonne Arnaud added a moving plea for financial help, and votes of thanks were proposed and seconded by Mr. H. S. Souttar and Sir John Broadbent.

#### NEW PREPARATIONS

**MANDELIX** (Elixir of Ammonium Mandelate, B.D.H.).—In THE LANCET of April 4th, 1936 (p. 769), H. E. Holling and R. Platt reported favourably on the treatment of urinary infections (pyelitis) with ammonium mandelate. This was prepared by the British Drug Houses Ltd. (London, N.1) in the hope that its use would obviate the necessity of giving ammonium chloride, which many patients find nauseous, whenever mandelic acid treatment is required. The elixir tried by Holling and Platt contained the equivalent of grs. 30 (2.0 g.) of mandelic acid per fluid ounce; but the preparation now marketed under the name of Mandelix contains in 2 fluid drachms the equivalent of the full therapeutic dose (3.0 g.) of mandelic acid. It is issued either separately or as part of an outfit embodying all that is necessary for a week's treatment. This includes 28 doses, a dozen capsules of ammonium chloride (for supplementary use if required), and equipment for determining the pH of the urine.

**CANNED PINEAPPLE JUICE, "DOLE" BRAND.**—This is the natural (unsweetened) juice of ripe Hawaiian pineapples and has been approved by the Committee on Foods of the American Medical Association. It is expressed from the shredded fruit, heated to 60°C., and centrifuged to remove suspended matter; it is then placed in cans which are sealed under "vacuum," heated in a cooker at 88°C. for less than ten minutes, and promptly cooled. According to the manufacturers the nutritional value of the raw pineapple is almost unimpaired by these processes. The vitamin-C content is slightly reduced but the juice remains, according to published investigations, a good source of vitamins A, B<sub>1</sub>, and C, and also contains B<sub>2</sub>. Among the advantages claimed for its use are that it raises the alkaline reserve of the blood plasma, increases renal elimination of waste products (urea), and stimulates the digestion of proteins in the stomach. Apart from these or other qualities it is an attractive addition to the diet, especially of children. The distributors are J. K. Husband and Co., Ltd., 10 Eastcheap, E.C.3.

THE May issue of the *Prescriber* is devoted to endocrinology, being the sixteenth annual issue on this subject. Each chapter treats of a ductless gland, and after a brief statement on its functions reviews the published advances of the past year. The journal is published from 65, Castle-street, Edinburgh 2.

**A POCKET TRANSILLUMINOSCOPE.**—Dr. M. E. El-Ibiary, writing from Ancylostoma and Bilharzia Hospital, No. 20, Cairo, refers to the "pocket transilluminoscope" described by Mr. Hamilton Bailey in THE LANCET of April 18th and informs us that two years ago he gave an account of a somewhat simpler instrument serving the same purpose which he named the "transoscope" (*Proc. Clin. Soc., Kasr-el-Ainy Hosp.*, 1934, vol. ii., No. 1.)

**A NEW SCREW-CAP.**—The United Glass Bottle Manufacturers, Ltd., have produced a double-shell metal cap for bottles and pots. This cap has all the advantages of the ordinary screw-cap, but by the use of two layers the outside presents a smooth, unbroken surface. This not only improves the appearance but also enhances the value of the receptacle, because the side of the cap ordinarily occupied by the thread of the screw is smooth and available for labels or designs. Any required lining can be fitted.

## ADDRESSES AND ORIGINAL ARTICLES

THE BIOCHEMICAL LESION IN  
VITAMIN B<sub>1</sub> DEFICIENCYAPPLICATION OF MODERN BIOCHEMICAL  
ANALYSIS IN ITS DIAGNOSIS \*

BY RUDOLPH A. PETERS, M.C., M.D., F.R.S.

WHITLEY PROFESSOR OF BIOCHEMISTRY IN THE  
UNIVERSITY OF OXFORD

WE are so accustomed to the detailed analysis upon the fixed tissue which is made possible by refined histological methods that we do not readily adjust to the idea that a new type of analysis is being steadily perfected by modern biochemical research. So far as the separation of one cell from another is concerned and the elucidation of differences in its pathological state, modern biochemistry is still very crude. We cannot work upon much less than 50 mg. of wet tissue, but we can obtain information from this of changes too subtle to be revealed upon the fixed histological specimen, changes in the behaviour of essential enzyme systems present. It really constitutes a new approach to pathological analysis, and has been exemplified in part by the work of Warburg,<sup>1</sup> Dickens,<sup>2</sup> and colleagues upon glycolysis and the cancer cell.

B<sub>1</sub>-DEFICIENCY IN THE PIGEON

An object of the present paper is to present an outline of one analysis of this type which is now in progress in the biochemistry department at Oxford. Our work had its origin in the wish to improve the pigeon test for vitamin B<sub>1</sub>. Anyone who has fed pigeons upon B<sub>1</sub>-deficient diets (such as polished rice) soon knows that there are two fairly well-marked different states produced, the acute and the chronic. The chronic are characterised by varying degrees of wing and leg weakness and spasticity; they often take a long time to cure upon accepted sources of vitamin B<sub>1</sub>; in young birds leg weakness may take a month of such treatment to effect a cure. In these it is easy to imagine the existence of a true polyneuritis, though it is doubtful whether it has been proved (Woollard,<sup>3</sup> Prickett<sup>4</sup>).

The acute symptoms are quite different from the chronic; they clear up with the greatest rapidity if vitamin B<sub>1</sub> is given, in under an hour when injected under the skull.<sup>5</sup> There is no evidence of histological change, nor could this be expected. Pigeons with these acute symptoms have been much described. It suffices to note here that they usually show opisthotonus, but more rarely forward symptoms, "emprosthotonus."<sup>6</sup> The bird either remains with the back of the head nearly touching the back, or exercises cartwheel convulsions. Previous to this the bird sees badly and does not respond when the finger is placed close to the eye. Exercise, noises, and strong light excite and exaggerate the symptoms; rest in the dark makes them quiescent. In the terminal stages there are usually failures of temperature regulation. Much work had been done upon this condition previous to the start of our own, about 1927, without the emergence of any definite conclusion as to their origin. It was the conviction that the secret of the condition lay in the brain rather than elsewhere that led naturally to the development of the following story.

\* The substance of a lecture delivered at the National Hospital, Queen-square.  
5882

Our first observations (Kinnersley and Peters<sup>7</sup>) were made by older biochemical methods, analysis of fixed tissues. Brains taken with a special T-shaped guillotine were plunged into liquid air within ten seconds of death. Speed is essential if the biochemical state of brain at death is required; about one minute suffices for the post-mortem conversion of the sugar present in a brain at death into lactic acid.<sup>8</sup> We concluded from this early work that there was more lactic acid than normal present at death in the brains of birds showing the acute symptoms, and that this increase took place especially and first in the optic lobes and lower parts of the brain. No changes could be detected in the cerebellum. The increased lactic acid had two possible origins, either from the blood or from local changes in the tissues. Increases of lactic acid in the blood of three avitaminous pigeons had been previously described by Collazo and Morelli.<sup>9</sup> We argued that the lactic acid change was local because of its uneven distribution and its failure to keep step with blood lactic acid. As a matter of fact there seems to be a difficulty in removing lactic acid in other parts of the body in the B<sub>1</sub>-deficient organism. The Japanese workers Hayasaka and Inawashiro<sup>10</sup> found that lactic acid disappeared more slowly from the blood in beri-beri patients after exercise, and R. B. Fisher<sup>11</sup> showed in Oxford that in the deficient pigeon after exercise lactic acid disappeared more slowly from the heart and muscles.

## ABNORMALITIES IN TISSUE RESPIRATION

With these abnormalities in the brain as a guide, the enzyme systems were next analysed by more modern methods. It will be realised now that tissue systems can be studied after removal from the body in various states of organisation. The most organised of such systems is the slice of tissue (Warburg), and the least the isolated single enzyme. The one chosen for study will depend upon the aim and upon local conditions. Owing to the nature of our material, pigeon's brain, we have found it best to work with brain tissue teased with a blunt bone spatula. It is well known that tissue preparations of this type take up more oxygen in presence of certain substances such as glucose than when studied alone. Study of the behaviour of such tissue systems in vitro in glucose and other solutions is now generally believed by biochemists to be of value in interpreting the biochemistry of such tissues in the body. The phenomena are not too artificial to be of value.

Accordingly we studied the oxygen uptake of the brain tissue in Barcroft microrespirometers with and without addition of glucose. This had been done before without paying attention to the parts of the brain, and without addition of this substrate.<sup>12</sup> It must be realised that the tissue must be fresh for this purpose. Freezing or leaving the tissue to stand inactivates the subsequent tissue respiration in vitro. With 100 mg. of brain and 3 c.cm. of Ringer phosphate solution, no certain difference between the respiration of normal and avitaminous pigeon's brain has been observed (Gavrilescu and Peters<sup>13</sup>). But with glucose present, there was no doubt that the respiration was lowered and, as in the case of the lactate accumulations, especially in the lower parts of the brain. Cured birds showed an increase. As we know now, the same phenomenon is found in vitro with lactate (CH<sub>3</sub>.CHOH.COOH) and pyruvate (CH<sub>3</sub>.CO.COOH), both of which substrates

must be regarded as lying within the field of intermediary carbohydrate metabolism. With Meiklejohn and Passmore<sup>14</sup> we became quite certain that the lowered oxygen uptake was specific for the lowered vitamin B<sub>1</sub> and was not due to the accompanying general inanition. The birds dosed with vitamin B<sub>1</sub> alone in water and not allowed to feed showed the improved brain condition.<sup>15</sup>

Summarising the evidence up to this point, we see that there are two differences found in these brains, both more marked in the lower parts, (a) increased lactate and (b) diminished tissue respiration in glucose or lactate solution.

CATALYTIC ACTION OF THE VITAMIN

So far the experiments did not decide absolutely whether the vitamin itself was missing from the tissue. It was natural to try the effect of adding vitamin B<sub>1</sub> in the early experiments with the concentrates and in the later with the pure crystalline vitamin B<sub>1</sub> which became available.<sup>16</sup>† We had the good fortune to find that the addition of vitamin B<sub>1</sub> largely restored the oxygen uptake in vitro. Moreover, there was a regular relation between the effect of vitamin on O<sub>2</sub> uptake and the amount of vitamin added up to a certain maximum amount. To make this precise, with the amount of tissue and solution used, as little as 1/10,000 mg. has a perceptible effect and 1/500 mg. is maximal in action. The vitamin is definitely a catalyst; with small amounts much more oxygen is taken up than would be required to oxidise the vitamin B<sub>1</sub> added; further an increase of the vitamin to 1/5 mg. (100 times) produces no further increase in O<sub>2</sub> uptake.<sup>17</sup> Fig. 1 shows the effect of vitamin in increasing the oxygen uptake over an hour period of respiration in the presence of pyruvate from a recent experiment.<sup>18</sup> The action

FIG. 1.—Illustrates increases in oxygen uptake in vitro of avitaminous pigeon's brain tissue due to addition of increasing amounts of crystalline vitamin B<sub>1</sub> (hydrochloride). Period 1-2 hours from beginning of experiment. Medium Ringer phosphate containing pyruvate.

is so regular that it can be used as a test for estimating the vitamin.<sup>16</sup> A very important point is that there is practically no effect of the vitamin upon the normal brain. To the above points (a) and (b) we can now add (c) that the lowered oxygen uptake in glucose, lactate, and pyruvate media was

† See note upon Chemistry of vitamin B<sub>1</sub> at end.

This work will not be clear to those unacquainted with the biochemical field without a slight digression. As a result of much labour, biochemists have produced a scheme for the coordination of certain essential features in tissue respiration, which probably represents a fairly close approximation to the facts. Oxygen is picked up from the blood (or elsewhere) by the cell by one enzyme system (known as the Warburg system) and passed by means of an inter-

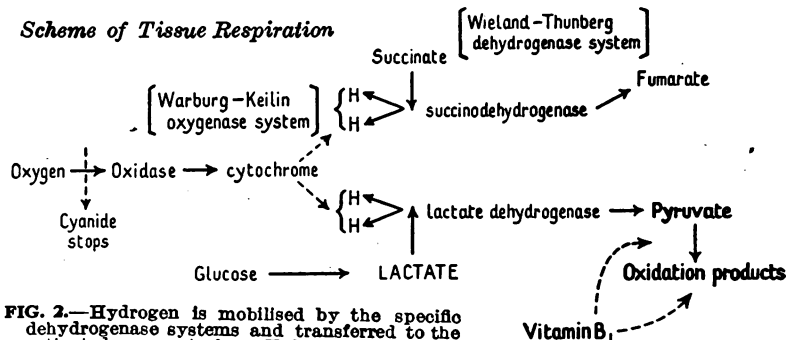

FIG. 2.—Hydrogen is mobilised by the specific dehydrogenase systems and transferred to the activated oxygen to form H<sub>2</sub>O<sub>2</sub>.

mediary carrier (Keilin's cytochrome) to the specific enzyme systems which activate lactate or other substances. Keilin's cytochrome (and probably the Warburg enzyme) are both porphyrin compounds allied to the blood-pigment.<sup>19</sup> Diagrammatically it is as in Fig. 2.

It should be emphasised that these are not mere paper schemes; the various factors have been isolated and can be made to work artificially by putting them together in vitro. It will be noted that KCN and narcotics interrupt the activity of the system at different sites. KCN for instance will inhibit the O<sub>2</sub> uptake for both the succinoxidase system and the lactate system. Succinate is a 4-carbon compound (COOH.CH<sub>2</sub>.CH<sub>2</sub>.COOH) present in the body in small amounts. The enzyme which oxidises it to fumaric acid (COOH.CH=CH.COOH) is widely distributed in brain and other tissues. Its importance as a test lies in the fact that it does not belong to the carbohydrate intermediary series of substances. Hence it forms a useful test in this connexion as to where the vitamin is acting, whether upon the oxidase or upon some specific dehydrogenase system. In strong contrast to the results with lactate, pyruvate, and glucose, we found no difference at all between the behaviour of normal and avitaminous brain tissues when succinate was used as the substrate.<sup>14</sup> Hence we can say definitely that B<sub>1</sub>-deficiency is affecting the sugar metabolism at some point related to the 3-carbon stage. Another fact in support of the carbohydrate concern of this vitamin is to be seen in observations on the respiratory quotient of the isolated tissue. Sinclair found that addition of vitamin B<sub>1</sub> raised this nearer to the true value for carbohydrate, upon average from 0.68 to 0.86.<sup>20</sup> I should add here that though most of our work has been done with phosphate solutions, the phenomena occur also in the more physiological bicarbonate media.

FURTHER OBSERVATIONS ON ITS ACTION

The facts so far considered really give substance to the two old theories of the action of vitamin B<sub>1</sub>: (1) that it was especially concerned with carbohydrate metabolism,<sup>21</sup> and (2) that it was connected with tissue respiration.<sup>22</sup> We can now decide that both views are correct; it is a catalyst needed for the

oxidative removal of one of the lower degradation products of carbohydrate metabolism.

Continuance of the work soon gave proof that the vitamin was not a lactate oxidase co-enzyme. The first shock arose from the work by Meiklejohn<sup>23</sup> in which he estimated the lactic acid removed by the respiring brain systems with and without vitamin. In spite of the increased oxygen uptake when vitamin was added, there was no increase in the lactic acid which disappeared. Hence B<sub>1</sub> was not directly increasing the removal of lactic acid. We therefore inspected the system more closely, and we found that the vitamin effect could be increased by warming the tissue during preparation and that addition of pyrophosphate also improved it. About the same time that this work with Sinclair<sup>24</sup> was proceeding Embden and Meyerhof<sup>25</sup> with their colleagues produced their new scheme for the stages of degradation of sugar in muscle, in which the energy of the sugar is made available by a rather detailed series of successive phosphorylations, and in which stress was laid upon the importance of pyruvic acid as a precursor of lactic acid. Long known in yeast fermentation, the significance of pyruvic acid was now raised for the animal. In the Embden-Meyerhof experiments the pyruvic acid was detected by the use of poisons; to this extent it could still be argued that its presence was an artefact. Qualitative tests for pyruvate (Simon and Piaux) are simple, a modified Rothera with more nitroprusside and strong ammonia, a blue-green colour indicates the presence of pyruvic acid. The pyruvate reaction is given strongly by the brain which has respired in lactate without addition of vitamin and is reduced by adding vitamin. It is not given by the normal brain unless this has been poisoned with iodoacetic acid. The metabolism of pyruvate in vitro was studied with Thompson<sup>26</sup> quantitatively and the following things established about it:

(1) It was never present with the normal respiring brain in appreciable amount.

(2) It was formed from lactate with avitaminous brain in vitro in absence but not in presence of vitamin.

(3) Vitamin caused the disappearance of added pyruvate.

(4) The ratio  $\frac{\text{extra oxygen taken up}}{\text{pyruvic acid disappearing}}$  with addition of vitamin was variable but for pyruvate had average 450 mm.<sup>3</sup>/mg.

(5) Practically no pyruvate was present in avitaminous brain at death.

We concluded that the vitamin was definitely concerned with the removal of pyruvate, but not directly. The experiments clinched the importance of pyruvic acid as an intermediary metabolite. In recent unpublished experiments with K. G. McGowan, the ratio  $\frac{O_2}{\text{pyruvic acid}}$  has been more accurately determined upon normal brain for pyruvate and oxygen uptake. It indicates roughly the same value (435 mm.<sup>3</sup>/mg.) as for the extra pyruvate disappearing, and that most of the pyruvate is actually burnt. Hence the vitamin must be concerned with this in the normal brain.

The next step in this work was to look for pyruvate elsewhere. Thompson found it in the blood of the avitaminous bird. The accompanying Table shows the values obtained by Thompson and Johnson<sup>27</sup> for the pyruvate in the blood of avitaminous pigeons and also rats at a similar stage of vitamin-B<sub>1</sub> deficiency. The increase is definite and there is a reduction upon cure of the animal. The pyruvate has been identified by the best chemical methods by Johnson.<sup>28</sup> It may be mentioned that an investigation with O'Brien has been conducted upon the

rats' brain<sup>28</sup>; the same abnormalities were found as in the pigeon but they were more difficult to demonstrate, and there was no evidence of localisation in the lower parts. It is really fortunate that circumstances compelled us to use the bird's brain for these studies, as the phenomena seem to be exaggerated in the pigeon as compared with the rat.

In the human, the presence of pyruvate in the blood in ordinary diseased conditions has not been

Table showing mg. Pyruvic Acid\* per 100 g. Blood

\* Estimated as bisulphite-binding substance. About 2.8 mg. is not actually pyruvic acid, so that the actual increase of pyruvic acid is larger than the figures indicate.

found by Johnson, Meiklejohn, Passmore, and Thompson<sup>30</sup>; in contrast to this a fascinating preliminary note by Platt and Lu<sup>31</sup> draws attention to the presence of pyruvate in the blood and c.s.f. of beri-beri patients in the Orient!

#### WHAT HAS BEEN LEARNT

We may now take stock of the position. A purely in-vitro research with brain tissue of the bird was started in the first instance to improve the test for vitamin B<sub>1</sub> and later extended to elucidate the enzyme with which the vitamin co-operated. It has not only helped to settle these problems but it has proved the existence of pyruvate in normal metabolism. It has also shown that an in-vitro research upon brain tissue which takes advantage of the in-vitro labours of biochemists, can be applied to in-vivo events. This is an important step in this field. It is further encouraging that the work has led to the detection of pyruvate in the blood of beri-beri patients, which may well prove diagnostic. Surely we could not have a better instance of the ultimately practical value of a purely academic research.

*Further intimate analysis of the condition.*—The finding that pyrophosphate improves the respiration in presence of vitamin B<sub>1</sub>, taken in relation to the work of Meyerhof and Lohmann, suggests that it improves the synthesis of adenosine triphosphate in the tissue; a direct test of this point with Sinclair gave a negative answer. At first there seemed to be no experimental support for the view that lactate was converted into pyruvate, which was then oxidised with the co-operation of vitamin B<sub>1</sub>. Both iodoacetic acid and fluoride were found by Peters, Rydin, and Thompson<sup>32</sup> to eliminate the vitamin effect, though the former inhibited pyruvate appearance and the latter increased it, with lactate as substrate. Upon this they put forward the view that vitamin B<sub>1</sub> in presence of pyrophosphate led to the formation of some substance (unknown) which then interacted with the lactate pyruvate system, to produce an increase in oxygen uptake. In more recent unpublished work,<sup>13</sup> the experimental evidence against the view that lactate is directly oxidised to pyruvate, which then interacts with vitamin B<sub>1</sub>, has been to some extent reduced, so that it is possible that this is the course of events, lactate (with pyrophosphate) → pyruvate, the latter being directly oxidised in presence of vitamin B<sub>1</sub>. Vitamin B<sub>1</sub> does not catalyse the interaction of pyruvate and α-glycerophosphate, a reaction which does not occur in brain,<sup>33</sup> nor does it act as catalyst in vacuo in the presence of methylene-blue (Rydin).

This finding of pyruvic acid is not the only instance of discovery of an intermediary carbohydrate metabolite in vitamin-B deficiency. In children, Geiger and Rosenberg<sup>34</sup> have described the appearance of methyl glyoxal, which is stated to clear up when giving vitamin-B concentrates. There has also been the claim that in animals methyl glyoxal will appear in vitamin-B deficiency.<sup>34</sup> In the case of the pigeon

where we seem to have a fairly pure vitamin-B<sub>1</sub> deficiency in the brain, there is no evidence at all that methyl glyoxal is present in the animals during these symptoms.<sup>13, 29</sup> It is still possible that the methyl glyoxal may arise as a result of some entity of the vitamin-B complex other than vitamin B<sub>1</sub>.

To return now to the *acute symptoms* themselves, we have been able to relate these definitely to biochemical changes in the brain; there is evidence that they are initially located in the optic lobes and lower parts of the brain. No biochemical change has so far been demonstrated in the cerebellum. Two views can be taken as to their origin: (1) they are due to toxic products, of which the only ones at present known are lactate and pyruvate; or (2) they are the result of the deficiency of the factor only. Both these views have been much debated. The question of some general intestinal toxæmia seems now eliminated. After the discovery of the lactate accumulations we inclined to the toxic view, lactate in excess being considered to be toxic<sup>7</sup>; but we ourselves and others<sup>36</sup> have not been successful in inducing symptoms by injections of lactate. There is therefore not much actual support for the toxicity of the lactate increases; in any case it is a normal metabolite. In the case of pyruvate the amounts present in the blood are very small, and there is not evidence of increased pyruvate in the brain at death. Hence experimental support for the idea of toxicity even by the accumulation of a normal metabolite in the brain-cells is non-existent. This leaves open the second view (2) the purely deficiency view. Upon this the absence of an important factor in the development of energy from carbohydrates would be sufficient to stop the normal functioning of some groups of nerve-cells. Those which normally had most work to do might be expected to run out of their supply of the catalyst vitamin B<sub>1</sub> sooner than others. In other words, interrupt the normal metabolism of glucose at any stage, and brain-cells do not function properly. As has been pointed out elsewhere,<sup>5</sup> several circumstances may lead to the development of these symptoms in pigeons, most of which can be considered to be interference with some stage of the sugar metabolism; we may mention asphyxia, insulin overdose, cyanide poisoning, and anaesthetics such as chloroform. This is particularly interesting in view of a rather similar analysis to the above which was carried out independently and at the same time by Quastel and colleagues<sup>37</sup> upon the action of narcotics. They found that narcotics influenced the lactate oxidations far more than the succinate. As a result of interference with the metabolism of the cell, we get failure of function. It is not necessary to invoke the idea of a toxic agent as such unless this view was extended to include H<sub>2</sub>O in the wrong place in a cell!

The prolonged nature of the *chronic symptoms* and the length of time needed for cure suggest some more extensive cell change. In the valuable work by Prickett<sup>4</sup> there are described lesions in the CNS. in rats due to vitamin-B<sub>1</sub> deficiency, or rather it would be more correct to say due to the heat labile entities of the vitamin-B complex, since the symptoms correspond more nearly to the B<sub>6</sub> rats. The lesions were disseminated foci of hæmorrhage or intense congestion of one or both sides, involving the nucleus of Deiters, the chief vestibular nucleus of Bechterew and nucleus solitarius, in approximately three-quarters of the animals. No changes in the peripheral nervous system could be satisfactorily correlated with the B deficiency. In spastic beri-beri in pigeons, disseminated foci of hæmorrhage were

found in pons, medulla, or cerebellum, and to a lesser extent in optic lobes and cerebral hemispheres. Such hæmorrhages have been observed in this laboratory. In the animals with chronic symptoms, Rydin has found evidence of vitamin-B<sub>1</sub> deficiency in the cerebral hemispheres with little change in the rest of the brain.

In conclusion it may be said that it is realised that the present studies are fragmentary and defective in several important respects, but there is no doubt as to the emphasis which they throw upon the importance of biochemistry in the central nervous system; it can reasonably be claimed that they are sufficiently promising to justify further studies upon these lines.

#### SUMMARY

New methods of biochemical enzyme analysis have been applied by workers in the Department of Biochemistry, Oxford, to the problem of the origin of acute opisthotonus symptoms in pigeons suffering from vitamin-B<sub>1</sub> deficiency. There is found to be a defect in the power of oxidising certain carbohydrate intermediates in the central nervous system (especially in the lower parts of the brain); the most important substances concerned specifically with the avitaminosis are lactic CH<sub>3</sub>CHOH.COOH and pyruvic acids; of these the "biochemical lesion" is most closely related to the oxidation of pyruvic acid (CH<sub>3</sub>COCOOH). Addition of minute amounts of crystalline vitamin B<sub>1</sub> in vitro to the avitaminous (not normal) brain tissue restores the diminished tissue respiration. This is not only the first clear instance of the experimental realisation of an in-vitro action of a vitamin, but it constitutes a useful method of assaying vitamin B<sub>1</sub>. This vitamin is a catalyst used by the tissue at some stage in the combustion of carbohydrate. Defect in this stage within the central nervous system will lead readily to convulsions. The researches decide that two prominent theories of the action of vitamin B<sub>1</sub> were both partly true. Both avitaminous pigeon and rat brain (but not normal) produce pyruvate in vitro; the presence of added vitamin B<sub>1</sub> removes this pyruvate. The blood of these animals with vitamin-B<sub>1</sub> deficiency has present pyruvic acid in relatively large amount, which disappears upon dosing with vitamin. In China, pyruvate has also been detected in the blood of beri-beri patients; so that there is a direct connexion between the animal and human conditions. These observations emphasise the importance of biochemical studies in relation to the central nervous system.

*Note upon chemistry of vitamin B<sub>1</sub>.*—This compound has now been isolated from yeast and rice polishings in crystalline form as the hydrochloride in several laboratories; the crystals are either thin plates or needles. It contains sulphur and has the formula

and according to the latest suggestions is a pyrimidine-thiazole compound. The thiazole nucleus has the skeleton—

The compound will cure pigeons in a daily dose of 2.0γ (0.002 mg.) which also constitutes the international vitamin B<sub>1</sub> unit. It is precipitable in very dilute solution by phosphotungstic acid, and gives a specific diazo test under special conditions. For references to literature see (38).

## ANÆMIA IN PREGNANCY

BY JOHN A. BOYCOTT, B.M. Oxon.

ASSISTANT IN THE PATHOLOGICAL DEPARTMENT AND HON.  
ASSISTANT IN THE OBSTETRIC UNIT, UNIVERSITY  
COLLEGE HOSPITAL, LONDON

THESE observations are based on the examination of 222 unselected patients attending the antenatal clinic at University College Hospital, the object of the inquiry being—

1. To investigate the frequency and degree of anæmia at this clinic.
2. To define the hæmatological characters of this anæmia.

All the patients were pregnant. None were seen before the third month of pregnancy; the majority were first seen during the fifth month. The patients were seen at irregular intervals, generally three or four times, and in some cases once or twice also in the puerperium. The period of pregnancy was calculated from the date of delivery, allowance being made for pre- and post-maturity.

A small proportion of the subjects were very poor, and a few had family incomes in the neighbourhood of £5 a week; the majority were of an intermediate status. No obvious connexion between the incidence of anæmia and social status, parity or age could be traced but the numbers involved were small.

## Methods

Hæmoglobin estimations were made with the Haldane hæmoglobinometer standardised at an oxygen capacity of 18.5 c.cm. per cent., equivalent to 13.8 g. of hæmoglobin. Red cells were counted by dilution with normal saline in a Bürker chamber. This was done as a routine only when the hæmoglobin level was below 80 per cent. Cell diameters were measured by the Price-Jones method. The films were fixed and stained in Jenner and counterstained with 0.5 per cent. aqueous eosin. Reticulocytes were counted by a wet method.<sup>1</sup> Test-meals were not done in many cases; the technique described by Strauss and Castle<sup>2</sup> was used.

## Criteria of Anæmia

The mean normal hæmoglobin of healthy non-pregnant women (100 cases) was found by Price-Jones<sup>3</sup> to be 98% on the Haldane scale; by the + and - 3 × the standard deviation rule he calculated a possible normal range of 85%-111%, and found an observed range of 90%-110%. Davidson<sup>4</sup> takes the normal for women as 98% (Haldane) ± 10%, i.e., 88%-108%. Other figures are difficult to compare exactly because other methods of determination have been used; in all cases quoted I have converted them to the Haldane equivalent. Osgood and Haskins<sup>5</sup> found 99.5%, Wintrobe<sup>6</sup> 99.7%, Jenkins and Don<sup>7</sup> 100%, Jerlov<sup>8</sup> 99.8%, all mean values for healthy women based on fifty or more observations. In most cases the observed range was more extensive than that found by Price-Jones.

In view of these findings I have thought it reasonable to regard those cases with Hb. > 80% as not grossly abnormal. The remainder will be labelled "anæmic" with the important exception of those in Table II. (v. seq.).

## Incidence of Anæmia Among Pregnant Subjects

Of my 222 cases 172 (78%) always had Hb. > 80%, 50 (22%) had Hb. < 80% on at least one occasion, and 25 (11%) had Hb. < 70%.

From a large group in Aberdeen Davidson<sup>4</sup> obtained the following figures:—

—	Ages.	No.	Percentage of women with—					Mean Hb.
			Hb. 90% +	80-89%	< 80%	< 70%	< 60%	
Pregnant women	15-44	819	12.5	38	49.5	17.5	5.5	78.1%
Parous women*	15-44	603	36	31	33	16	10	81.3%

\* Not pregnant.

The difference in mean Hb. between parous and pregnant women in the same age-group is not

significant. Both categories show a higher incidence of anæmia than the nulliparæ and parous women aged 45 + which he examined in the same period.

Mackay<sup>9</sup> examined two groups: mothers (not pregnant) bringing children to hospital, and pregnant girls in a home. Of the latter 56% had Hb. 70-84% and 4.5% Hb. < 70%. Davies and Shelley<sup>10</sup> examined fifty patients in a London antenatal clinic. Of these six became anæmic; no definition of anæmia is given but the hæmoglobin range of these was 41-68%. The remainder showed an average fall of 8% in the hæmoglobin during pregnancy which was not considered significant. Davidson, Mackay and Davies and Shelley all used the standard Haldane hæmoglobinometer.

There are several other series of observations on the occurrence of anæmia in pregnancy in which the method of hæmoglobin estimation makes comparison more difficult. Balfour and Drury<sup>11</sup> examined 311 pregnant women in Durham and Tyneside with a Dare hæmoglobinometer calibrated in Haldane equivalents. 14.5% had Hb. < 80% and 7.4% Hb < 70%. Galloway<sup>12</sup> found that, of 222 pregnant patients, 65% gave hæmoglobin readings less than 65% on the Sahli scale, equivalent to 81% (Haldane) if the Sahli instrument is standardised at 17.3 g.%. Lyon<sup>13</sup> examined 177 patients at term by Sahli's method and found them to range from 50-95%

(= 62-118%, Haldane). About an equal proportion (32%) of these and a control group of gynæcological patients had Hb. < 88% (Haldane). Bland, Goldstein and First<sup>14</sup> examined 1000 pregnant women with a Dare instrument. As no standardisation of the hæmoglobinometer is given comparison is impossible, but the findings appear to be of the same order as those of Lyon.

Richter et al.<sup>17</sup> examined 99 white and coloured patients with a Sahli hæmoglobinometer calibrated at 14.8 g.% = 100%. Many were of poor social standing, with dietary insufficiency and focal sepsis the rule. 78% had Hb. < 75% (Haldane). Harvey<sup>18</sup> found a mean hæmoglobin of 64.5% for 100 women in labour, using a Sahli instrument calibrated at 21.3 g.% = 100%. This is equivalent to 99% on the Haldane scale. Adair<sup>21</sup> reports that, of 1176 new patients admitted to an antenatal clinic, 23% had less than 10 g.% hæmoglobin (approximately 72% on the Haldane scale). Mussey<sup>16</sup> found that of 82 patients all showed a fall in hæmoglobin values during pregnancy but only 16 were to be regarded as "anæmic." The figures of Galloway, Lyon, Bland, Richter, Harvey, Adair, and Mussey are all derived from the U.S.A. Adamson and Smith<sup>23</sup> in Canada found that 20% of 116 normal pregnant women had Hb. < 74% (Haldane.) McGeorge<sup>24</sup> in New Zealand, out of 100 consecutive cases at an

Da. = Dare: calibrated in Haldane equivalents.

antenatal clinic found 16 with Hb. < 75% and 2 with Hb. < 60% (Haldane).

Jerlov<sup>8</sup> in Denmark, using an Autenrieth hæmoglobinometer, examined 1143 pregnant women of whom 74.1% had Hb. > 76%; of the remainder 2.7% had Hb. 43-54%, 13.9% Hb. 55-65%, and the rest Hb. 66-76% (Haldane equivalents). Gram,<sup>15</sup> also in Denmark, examined a short series of pregnant women, some of whose hæmoglobin values fell 20% below the normal which he had established for healthy women.

Schultz<sup>20</sup> found only 3% of anæmic patients among 567 examined; he believed these to have been anæmic before pregnancy. Esch<sup>22</sup> examined 700 women in pregnancy, of whom 500 were primiparæ and 200 multiparæ. The estimations were made with a standardised Sahli hæmoglobinometer. The range of values was 56-112% (Haldane) and the majority lay between 75% and 93%. Brindeau and Theodorides<sup>19</sup> found a mean hæmoglobin of 13.58 g. % (98% Haldane) in 30 normal pregnant women, with a tendency for the values to be lower than in normal women. These authors worked in France, and Esch and Schultz in Germany.

The sum of experience seems to be that the average level of hæmoglobin is lower among pregnant than among non-pregnant women. Individual patients may show a small decrease in hæmoglobin values in pregnancy with recovery about the time of delivery. Different authors, however, give very different figures for the occurrence of anæmia of more than a slight degree in pregnancy (Table I.). This is well shown in the figures from this country. Davidson in Aberdeen found a considerably higher number of anæmic patients than were found by Davies and Shelley, or myself in London, or by Balfour and Drury in Durham and Tyneside. Mackay's figures show an even lower incidence than the other London observations but, as the subjects were living in an institution, are hardly comparable with those derived from hospital clinics. Some of the American and continental figures seem to indicate a greater prevalence of anæmia in pregnancy than in England, but the comparison must not be pressed too far on account of the different methods employed. Richter's figures from U.S.A. show a considerably higher incidence than those of any other author. The possible factors which may explain these differences will be discussed later.

**Hæmatological Characters of the Anæmia**

Of the 222 cases observed at University College Hospital, fifty (22%) were found to have Hb. < 80% on at least one attendance at the clinic. From these we may exclude for the time fourteen who had either associated disease or a history of hæmorrhage; eleven had Hb. < 70%. They will be discussed later. Of the remaining thirty-six, ten (two of which had Hb. < 70%) were not fully examined and will not be dealt with further. The rest were divided into two groups, those with colour indices 0.91-1.07, the limits of normality described by Price-Jones,<sup>3</sup> and those with colour indices less than 0.91 (Tables II. and III.). No case was found with a colour-index greater than 1.07.

It will be seen that, of the thirteen cases whose colour-indices lie within normal limits (Table II.), none shows a hæmoglobin level below 67%, and several have values below 80% on one occasion only. The colour-indices vary from 0.91 to 1.05. The mean diameters are always within normal limits; one case (1278) shows a rather high mean diameter

which was maintained in two post-partum estimations (not shown). The variability is in all cases within normal range but rather higher than the mean established by Price-Jones.<sup>25</sup> The reticulocytes were never found to be increased. Except for the low hæmoglobin level and corresponding fall

TABLE II.—Thirteen Cases having Colour-indices 0.91-1.07

10 never showed Hb. < 70%.  
3 showed Hb. < 70% on at least one occasion.  
Lowest recorded value of Hb. = 67%.  
No case showed more than 5% hypochromic cells.  
The percentage of reticulocytes was never found to be raised above normal.

Normal M.D. = 7.202µ ± 0.172µ ; normal variability = 6.326 ± 0.331 per cent (Price-Jones<sup>25</sup>).  
M.D. (mean diameter) and v. (variability); nil in Cases 1296 to 1556.

in the red cell count there is no ground for considering these cases abnormal hæmatologically. There is no observed constant direction of change in the hæmoglobin level to correspond with the stage of pregnancy, as is seen when all the normal cases in the series are examined together (v. seq.) but the numbers concerned are small.

In contrast to these cases the thirteen with low colour-indices present abnormal features (Table III.). The hæmoglobin levels are lower; the red cell count is often low but never to an extent to correspond with the hæmoglobin level. The colour-indices vary from 0.89 to 0.6. The mean diameters are below the normal mean in all cases. Many of them fall within normal limits but they bear, usually, a fairly close relation to the hæmoglobin level. This is well illustrated by Case 1358, where the progressive fall in hæmoglobin 90%-80%-70% is accompanied by a fall in the mean diameter 7.223 µ-6.881 µ-6.613 µ. One case (1333) shows no change in mean diameter. The variability is usually increased, but does not appear to run so closely parallel with the hæmoglobin level as does the mean diameter (e.g., 1358 shows a slight decrease in variability as the mean diameter falls). Hypochromic cells are numerous in the more severely anæmic cases and appear to occur in an inverse ratio to the hæmoglobin level. I am not convinced that the technique of staining for these

cells is satisfactory for differential counting, since different results could be obtained in different parts of the same blood film. The reticulocytes were never increased except when iron treatment was given. In all these particulars the blood films are indis-

tinguishable from those from cases of Witts's hypochromic anæmia. Price-Jones<sup>28</sup> quotes the figures of eight cases of Witts's anæmia before and after treatment, which are of the same order as those observed by me. In neither Witts' anæmia nor this hypochromic anæmia of pregnancy is there spontaneous remission, but both diseases appear to respond to adequate iron treatment—e.g., Case 1272. It is not however suggested that the diseases are identical except as regards the blood picture produced and the response to treatment. Several of the cases which have been excluded as having some

complicating feature have blood pictures of this type.

In Price-Jones's figures for Witts's anæmia and in my series (Table III.) there is a tendency for the mean diameter to be low and the percentage of hypochromic cells to be high with a low level of hæmoglobin. In my figures this is confirmed by significant coefficients of correlation between hæmoglobin and mean diameter ( $r = +0.735, \pm 0.109$ ), and hæmoglobin and the number of hypochromic cells ( $r = -0.704, \pm 0.122$ ). No correlation was found between hæmoglobin and variability. In pernicious anæmia Price-Jones found a significant correlation between hæmoglobin and variability but none between hæmoglobin and mean diameter.

It was thought worth while to examine some of each class in the first week of the puerperium. Those of normal colour-index showed a tendency to improve spontaneously while the others showed no change. Since the blood losses at delivery are approximate estimations, it is improbable that observations at this time are of value unless a large number of cases are examined. An attempt was made to examine the patients and their children between six and nine months after delivery to detect any cases of the anæmia occurring in the children of anæmic mothers (Strauss<sup>29</sup>). This appeared to be a possible way of separating a nutritional iron deficiency in the mother from other conditions causing a low hæmoglobin level. No case of such anæmia could be found among those examined (about half those written for), but the majority of the children of those severely anæmic had been artificially fed and were attending welfare centres.

In comparing these two classes (with normal and subnormal colour-indices) there were noticeable clinical distinctions. Those of normal colour-index were apparently healthy women, who made no complaint of the subjective features of anæmia, breathlessness, faintness, or "palpitations." The majority of the second class were in poor general health; symptoms of anæmia were common. The obstetric histories of neither group were obviously worse than those of the 172 cases classed as normal, but two cases with subnormal colour-indices had severe postpartum hæmorrhages. Except in two cases (both in the second group) the family income of these cases was up to the general standard, and (with these two exceptions) the patients appeared to have adequate diets. Nevertheless the difficulties in assessing the actual diet of out-patients are too great to make any conclusion on this ground of value. Fractional test-meals, when performed, did not show any difference between the two groups; hypochlorhydria or achlorhydria, even after histamine, was found in all cases.

From this evidence it has been assumed that two conditions may be distinguished, a true anæmia, and lowering of the hæmoglobin level probably due to dilution of the blood. In future the thirteen cases in Table II. will not be referred to as "anæmic." That the blood volume is increased in pregnancy is an old observation, but much of the early evidence is conflicting. Recently Dieckmann and Wegner<sup>29</sup> have reviewed the evidence and find that the majority of observations show an average increase in blood volume in pregnant women of 10–20%. Their own experiments were made by the dye method of Keith and Rowntree<sup>30</sup>; this is probably less accurate than the carbon monoxide method but has an advantage peculiar to these observations that the placenta is impermeable to the dye employed. They found an

TABLE IV.—*Hæmoglobin Level in 152 Normal Pregnant Patients: 419 Observations*

Duration of pregnancy in weeks ..	12-15	16-19	20-21	22-23	24-25	26-27	28-29	30-31	32-33	34-35	36-37	38-39

Whereas no two adjoining columns show significant differences, there is a statistical difference between the highest and lowest means—e.g., 22-23 and 32-33 weeks.

average increase in blood volume of 23%, beginning in the first three months of pregnancy and continuing to term. The increase was mostly in the plasma volume. A notable feature of their results is the inconsistency of the increase, some cases showing none or even a decrease. Richter<sup>17</sup> examined the blood volume (by a dye method), red cell count and hæmoglobin in fourteen cases before and after delivery. There was fairly close inverse correlation between blood volume and hæmoglobin. Schultz<sup>20</sup> considered that 50% of the patients he examined in pregnancy showed a dilution of the blood and only 3% were truly anæmic.

Some fall in the hæmoglobin level in normal pregnancy has been reported by many authors (Gram,<sup>15</sup> Einar Rud,<sup>31</sup> Kerwin and Collins,<sup>32</sup> Suwa,<sup>33</sup> Nalle,<sup>34</sup> McGeorge,<sup>24</sup> Davies and Shelley<sup>10</sup>). This has usually been described as the "physiological" anæmia of pregnancy in distinction to the severer grades of anæmia which cause symptoms. Kühnel<sup>35</sup> examined fifteen women at fortnightly intervals from the second month of pregnancy, and found a progressive fall, of hæmoglobin and cells equally, until the thirty-second week, when a slight rise occurred. Shortly before delivery there was a fall in the hæmoglobin only. Mussey<sup>18</sup> found that of 82 pregnant patients, 71% showed an equal reduction of red cells and hæmoglobin, while the colour-index of the rest fell to some extent. Both these observations support the idea of hydræmia as the cause of the physiological anæmia of pregnancy. Jerlov's findings,<sup>8</sup> that, of 141 untreated patients, 64% showed a fall of hæmoglobin in pregnancy, 19% showed no change and 17% a rise, agree with the observation that the increase of blood volume is inconsistent. If this fall in hæmoglobin is due to hydræmia, treatment with iron should have no effect and recovery should be spontaneous. Of 50 cases, Bland and Goldstein<sup>52</sup> report spontaneous return of the hæmoglobin to normal after delivery in all but four. Richter<sup>17</sup> found little difference between cases treated with iron and liver and those untreated, but the former showed a quicker post-partum recovery. Jerlov<sup>8</sup> however reports that 90% of women treated with iron during pregnancy show a slight rise in hæmoglobin: the hæmoglobin levels do not return to normal. The incidence of anæmia in his series was high (Table I.) and it is reasonable to suppose that iron deficiency was common in the group he examined. Irving<sup>36</sup> showed that there is a demonstrable improvement in red cells and hæmoglobin in eighteen pregnant women treated with iron and copper compared with forty-three untreated cases. No attempt was made by this author to distinguish those cases which responded to treatment from those who showed no change, and the improvement is an average one. It seems probable that iron shortage is not uncommon in a slight degree (v. seq.) but that the main cause of the fall

of hæmoglobin, apart from frank anæmia, is a dilution of the blood.

#### SUMMARY

Twenty-six cases having Hb. < 80% were examined in detail; their histories and present states gave ground for supposing that the low level of hæmoglobin was due to pregnancy alone. It was found that they were equally divided into those with normal and those with subnormal colour-indices. These two classes could also be distinguished on clinical and hæmatological grounds. There is evidence to show that there is an inconsistent increase in the plasma volume in pregnancy causing a dilution of the red cells, and it has been suggested that the existence of the group with low hæmoglobin figures and normal colour-indices is explicable on this basis. On the grounds of hæmatological resemblances and satisfactory response to iron treatment the group with low colour-indices have been assigned to the class of anæmia due to iron deficiency. The two groups are not mutually exclusive.

#### Normal Hæmoglobin Level in Pregnancy

Although it is impossible to exclude a slight degree of iron deficiency, if this really exists in some patients, it has been thought worth while to construct Table IV. from the hæmoglobin figures of those cases whose histories were accurately known, who had no complicating disease and whose colour-indices lay within normal limits. It will be seen that the mean hæmoglobin level for each fortnight forms a fairly regular curve, reaching a minimum at 34-35 weeks and rising slightly before delivery. The variability in any fortnight is large, and examination of the data of individual cases shows that many maintained a constantly high level throughout pregnancy. Such a variation between individual cases was a feature of Wiekmann and Degner's blood volume estimations.

#### Nature of the Anæmia

Strauss<sup>37</sup> makes a clear distinction between hydræmia and hypochromic anæmia occurring in pregnancy, and reserves the name "physiological" anæmia of pregnancy for the former. The hypochromic anæmia of pregnancy he regards as an iron-deficiency anæmia arising either from deficient diet or from deficient gastric secretion. To either of these must be added the drain of the foetal demands for iron. Of the cases which he examined, those whose gastric secretion was normal had a diet deficient in animal protein and green vegetables. It is at present uncertain if the cause of this anæmia is a true deficiency of iron or a failure, perhaps due to defective acid secretion, to utilise iron except in large doses. The latter appears more probable. I use the words "iron deficiency" without prejudice. The foetus is born with five times the iron content of the adult per unit body-weight and receives no appreciable amount from the milk. Strauss<sup>28</sup> has

shown that there is a correlation between maternal hæmoglobin in pregnancy and the infant's hæmoglobin some months later—i.e., when the iron store of the infant is reaching exhaustion. This agrees well with Mackay's findings in nutritional anæmia in infants.<sup>38</sup> Both maternal and infantile anæmias respond to adequate iron treatment.

Table III. shows thirteen cases of anæmia which must be regarded as of this type. Where these cases have been treated there has been a response to iron. An attempt to find nutritional anæmia in the children failed (*v. ante*). The hæmatological similarity to Witts's hypochromic anæmia gives confirmatory evidence of a similar essential ætiology, iron deficiency.

Schultz<sup>20</sup> and Mussey<sup>16</sup> suggest that anæmia exists before pregnancy in these cases. This is a possibility hard to disprove. Each patient was closely questioned and, where the answers suggested a pre-existing anæmia, was excluded from this series. Five cases were rejected for this reason. It is possible that iron deficiency in pregnancy is more common than the number of anæmic patients in this series would suggest. Such a case as 1296 (Table II.), where the colour-index is at the lowest level of normality, may well be a case of combined hydræmia and anæmia. Cases 1444, 1413, and 1293 (Table III.) are probably examples of a relatively slight iron deficiency. The existence of such cases would help to explain the beneficial effect of iron treatment in unselected cases (Richter, Jerlov, Irving, *v. ante*).

The fourteen cases in which there is reasonable ground for recognising a cause of anæmia other than pregnancy may be divided as follows :

1. Five which had (or were reasonably suspected of having) anæmia prior to pregnancy ; four had Hb. < 70%. Of these, one showed the signs of Witts's hypochromic anæmia ; a recent examination of the patient after intensive iron treatment showed considerable improvement in the anæmia and disappearance of the "spoon nails." One was a case of myxœdema.
2. Three had hæmorrhage during or immediately before pregnancy. All had Hb. < 70%.
3. Three had pyelitis. Only one had Hb. < 70%.
4. Three had heart disease with histories of recurrent attacks of failure. Two (733, 1247) had been anæmic in previous pregnancies. All had Hb. < 70%.

Of those with pre-existing anæmia or a history of hæmorrhage all were of the iron-deficiency type except one. In cases of pyelitis it was very noticeable how quickly the hæmoglobin fell with the onset of fever. The three cases of severe heart disease met with among 222 patients all came into this group. If this is more than a chance occurrence it is difficult to explain ; possibly atrophic changes occur in the gastric mucosa consequent on prolonged congestion. The proportion of poor general health and bad obstetric histories among this group of "complicated anæmia" was remarkably high. No case of the macrocytic anæmia of pregnancy was met with in this series. It does not seem to be related in any way to the hypochromic form.

#### SUMMARY

Twenty-seven cases of anæmia are discussed. Thirteen of these have been ascribed to iron deficiency, due to the demands of the fœtus in combination with either dietary insufficiency or defective utilisation of iron. The remainder occurred in patients who had some complicating disease ; the majority of these were of the hypochromic type.

#### Factors Contributory to Anæmia

Of 222 patients 27 were found to be anæmic, of whom 13 may reasonably be supposed to have

developed anæmia as the direct result of pregnancy. Comparing the anæmic and non-anæmic groups there did not appear to be any connexion between anæmia and toxæmia or any other complication of pregnancy beyond those mentioned above. The numbers of these are too small to be anything but suggestive. Gram<sup>15</sup> found no hæmatological abnormality in 3 cases of eclampsia. O'Sullivan<sup>39</sup> found that 15 of 19 patients with albuminuria and 21 of 32 with pyelitis suffered from hypochromic anæmia in pregnancy ; iron treatment raised the hæmoglobin level and improved the albuminuria. Steiglitz<sup>40</sup> found that the presence of renal or cardiovascular disease hindered the treatment of anæmia in pregnancy. Moore<sup>41</sup> found nephritic patients to show a lower hæmoglobin level than normal pregnant patients. Richter<sup>17</sup> attributes the high incidence of anæmia in pregnancy in a mixed group of whites and negroes to, among other things, the prevalence of focal sepsis. That such diseases concurrent with pregnancy should cause or exaggerate anæmia fits in with clinical experience in non-pregnant patients. Iron treatment in such cases is often unsatisfactory until the primary disease is controlled.

Other possible factors are social status, age, and parity. As has been stated no correlation could be found between these factors and anæmia in this series. However, the high incidence of anæmia in Aberdeen (Davidson, Table I.) as compared with that found by Davies and Shelley and myself in London suggests that the first may influence the occurrence of anæmia. Davidson<sup>4</sup> describes his subjects as "a cross-section of the poorest classes" ; many did not present themselves on account of symptoms of ill-health. He states that a large number came from families in which the wage-earner was unemployed. The class of patient at the Royal Free Hospital (Davies and Shelley) is probably of the same nature as that I have examined, in which unemployment, although not unknown, is relatively uncommon. I am informed by those who have experience of Aberdeen and this part of London that there is a real difference in the class of patient attending antenatal clinics in the two areas. Balfour and Drury<sup>11</sup> compared the number of cases of anæmia in pregnancy among the wives of employed and unemployed workers attending antenatal clinics in County Durham and on Tyneside. No patient was admitted to the employed group whose weekly family income did not amount to 10s. or more per head, or to the unemployed group whose income was more than 8s. per head. They found that, of a total of 311 patients, divided about equally between the two groups, 11.2% of the former and 16.4% of the latter had Hb. < 70% (Haldane). The numbers examined were small, and the figures would be more striking if they showed a higher incidence of anæmia than those derived from the apparently better-to-do working-class population in London. The authors consider that many of the most undernourished cases were too feeble to attend the clinic. Although the family income was always recorded in my series, no correlation between this and the incidence of anæmia was apparent. Harvey<sup>42</sup> from the study of 100 pregnant women in the U.S.A. came to the conclusion that social status (and parity) had no effect on the incidence of anæmia. If social status is to have effect it will most probably do so through the patients' diet. Davidson<sup>4</sup> has shown that the population which he studied is on the border-line of iron starvation, and Strauss<sup>37</sup> that the absence of animal protein and vegetables from the diet is

conducive to anæmia in pregnancy. Data however are lacking for the proof that a barely sufficient diet will, in more than a minority of cases, produce anæmia, even under the strain on the hæmatopoietic system caused by pregnancy. Although, as has been shown, hydræmia may produce a pseudo-anæmia in pregnancy, this does not seem to invalidate the comparison of the incidence of anæmia in different groups. There is, of course, a possibility that there are unrecognised factors influencing the increase in blood volume (Green-Armytage<sup>42</sup>).

Age is recognised as a dangerous factor in obstetric risks as a whole (Robinson,<sup>43</sup> Douglas and McKinlay<sup>44</sup>), but it is difficult in a small series to separate it from multiparity. Since the majority of cases of anæmia in pregnancy are due to an iron deficiency, it is reasonable to suppose that repeated pregnancies would be a drain on the iron stores of the body. 13.5% of the subjects in this series were in their fifth or later pregnancy. Of the normals 13% and of the anæmic 16% came into this category, findings which cannot be considered significant. Davies and Shelley<sup>10</sup> found that a large proportion of women anæmic in the puerperium had born upwards of seven children. Kerwin and Collins<sup>32</sup> also found a greater tendency to anæmia in old multiparæ than in the remainder of their patients. Davidson<sup>4</sup> regards menstruation and repeated pregnancies as a potential source of anæmia. Douglas and McKinlay,<sup>44</sup> from the study of maternal deaths, state that the liability to death from "severe anæmia" (usually apparently of the macrocytic type, v. seq.) increases with age and parity. Moreover a large number of pregnancies is traditionally associated with the type of subject likely to suffer from poor circumstances and a deficient diet. Nalle<sup>34</sup> makes the interesting observation that, at the same period of pregnancy, there is a close correspondence in the hæmoglobin level in successive pregnancies.

#### SUMMARY

Although the numbers in this series are too small to establish the pre-eminence of any factors as a cause of anæmia in pregnancy, the evidence goes to show that diseases which cause anæmia in the normal subject also predispose to anæmia in pregnancy. Although the data are suggestive, it is not proved that social status, age, or parity affect the incidence of anæmia.

#### Effect of Anæmia on Pregnancy

Mackay<sup>9</sup> has suggested that anæmia may be a predisposing factor in maternal infection on the analogy of the greater susceptibility to infection of anæmic infants. Four cases of puerperal morbidity occurred in my series with no fatality; two were among the anæmic and two among the normal cases. Two of the anæmic cases in Table III. (263/35 and 1272) had severe postpartum hæmorrhage, but apart from these the obstetric histories of the 13 cases were uneventful. The 14 cases of "complicated anæmia" showed an unduly high incidence of obstetric catastrophes, but it would not be just to attribute these to the anæmia alone. It seems probable that anæmia does not become dangerous in pregnancy (apart from the tendency to anæmia in the child) until a hæmoglobin level is reached, lower than is common in this country. Evans<sup>45</sup> reports that no case of "severe anæmia" occurred in 4083 consecutive patients at Queen Charlotte's Hospital in 1926-27. Balfour<sup>46</sup> quotes one case in 12,000 deliveries at the Rotunda Hospital (1921-23), one case at Queen Charlotte's Hospital in 1800 (1923), and

no cases at the Simpson Memorial Hospital, Edinburgh, in 1600 (1923). Douglas and McKinlay<sup>44</sup> classified 19 of 2527 maternal deaths in Scotland (1928-32) as due to severe anæmia. Most of these were known to have been of the pernicious type and deaths from "secondary anæmia" were classed under the primary condition. The macrocytic anæmia of pregnancy and pernicious anæmia occurring in pregnancy have deserved, at any rate before the introduction of liver treatment, a poor prognosis (Osler<sup>47</sup>) but these diseases are evidently rare in temperate climates (Whitby<sup>48</sup>). The tropical macrocytic anæmia is apparently responsible for a very high maternal and fetal mortality (Balfour,<sup>46</sup> McSwiney<sup>49</sup>). McSwiney says that it is unusual for a pregnancy to proceed to term and stillbirths are common. King<sup>50</sup> considers that the anæmia alone is the cause of the frequency of abortion and premature labour in patients suffering from hookworm disease. Wickramasuriya<sup>51</sup> in discussing the effect of hookworm infection on pregnancy says that where the hæmoglobin is less than 30 per cent. obstetric shock and postpartum hæmorrhage are frequent, the degree of shock depending on the degree of anæmia. I have seen no case in this series with less than Hb. 48%, but recently have had the opportunity of examining a pregnant patient with Hb. 30% and an anæmia of the hypochromic type, who subsequently had an uneventful labour and puerperium. Where obstetric disasters have occurred in this series poor general health has usually been a more prominent feature than anæmia. Reviewing the evidence it appears that anæmia of a hypochromic type, likely to be dangerous per se, is uncommon in this country (Table I.).

#### Conclusions

1. 22 per cent. of the patients attending the University College Hospital antenatal clinic had less than 80 per cent. hæmoglobin (Haldane). This incidence is compared with that recorded from other sources. It is of the same order as that observed elsewhere in England and rather less than in Aberdeen.

2. The common anæmia of pregnancy in this country is of the hypochromic type and would appear to be due to iron deficiency.

3. Increase of blood volume may cause an apparent anæmia in pregnancy by reason of the temporary fall in hæmoglobin and red cells. Such a condition may be distinguished from a true anæmia by the blood picture, but may coexist with a true anæmia.

4. Anæmia is probably not a serious risk in pregnancy in this country.

5. The effect of intercurrent disease, social status, age, and parity on the causation of anæmia is discussed.

6. The common anæmia of pregnancy responds well to adequate iron treatment unless there is complicating disease.

My thanks are due to Prof. F. J. Browne for the opportunity to investigate his cases and to Mr. J. G. H. Ince for his assistance with clinical details.

## ACUTE SUPPURATIVE THYROIDITIS

By ROBERT COOPE, M.D., B.Sc. Liverp.,  
M.R.C.P. Lond.

HON. ASSISTANT PHYSICIAN, LIVERPOOL ROYAL INFIRMARY;  
VISITING PHYSICIAN, MILL-ROAD INFIRMARY, LIVERPOOL;  
HON. PHYSICIAN, LIVERPOOL HOSPITAL FOR CONSUMPTION  
AND DISEASES OF THE CHEST; AND

L. FINDLAY, M.D. Liverp.

MEDICAL SUPERINTENDENT, MILL ROAD INFIRMARY,  
LIVERPOOL

ACUTE thyroiditis is rare. Hagenbuch in 1921 found only 43 cases in nearly 46,000 surgical and medical admissions at the Basle Clinic over a period of ten years. Joll (1931) has seen only 2 cases in a series of over 2000 patients admitted to hospital with goitre. Acute non-suppurative inflammation of the thyroid may resolve after about seven to ten days; rarely it may progress to abscess formation. In the Lahey Clinic (Clute and Smith, 1927) only 1 case of frank suppurative thyroiditis was encountered in a series of nearly 1200 cases of thyroid disease, and out of 3000 operations on the thyroid, only 3 were for thyroiditis followed by abscess. Robertson in 1911, reporting 3 cases of his own of acute inflammation of the gland, collected a further 93 from the literature; in the few instances where thyroiditis had developed as a complication of either pneumonia or of puerperal fever, he noted that suppuration invariably followed.

The inflammation may arise by direct infection (Lambert Rogers has reported an instance of abscess following a penetrating wound of the thyroid); the infection may spread from structures near by, though the fascial architecture in the neck, with the fusion of the superficial and pretracheal layers of the deep fascia to form a tough capsule to the thyroid, discourages such invasion; or the infection may be carried by the blood stream.

A distinction has been made between inflammation arising in a normal thyroid gland and that developing in a goitrous (usually adenomatous) gland, the latter condition being termed "strumitis." There seems to be little point in this difference of terminology, though some authors think that an already diseased gland is much more liable to infection. Among

Robertson's collection of 96 cases, goitre was already present in 31; and out of 67 cases of acute thyroiditis studied by Burhans (1928), adenomatous goitre was already present in 24. Moreover, an annotation in THE LANCET (1927) suggests that abscess formation is much more liable to follow acute thyroiditis in a goitrous than in a normal gland.

The most common pathway of infection is by the blood stream, either in association with generalised infections such as pneumonia, typhoid fever, influenza, puerperal fever, and various streptococcal infections; or by metastatic spread from alveolar abscess (Thorburn), tonsillitis, nasal sinusitis, gonorrhoea (Pic, Delore, and Paufigue), or urinary tract infection (Salleras and Colodrero). Crotti in 1918 said of Koher, who was the first to appreciate the usual origin of the condition:

"In the far-sightedness of his genius, although at the time he did not have bacteriology to support his theoretical views, he claimed that every acute thyroiditis or strumitis was due to metastasis of an infectious agent located somewhere in the organism, or originating from the intestinal canal. Later bacteriological findings proved the correctness of such views."

Several cases of acute suppurative thyroiditis following pneumonia have already been reported. Of Robertson's 96 cases already referred to, 6 occurred as a complication of pneumonia; bacteriological examination was made, however, in only 7 of the whole series, in 4 of which pneumococci were isolated from the pus of the thyroid abscess. Of Burhan's 67 cases of acute thyroiditis, 9 followed pneumonia; of Hagenbuch's 43 cases, 9 followed pneumonia. Eberts, Fitzgerald, and Silver in 1929 described a case of pneumococcal suppurative thyroiditis in a man of fifty who had pneumonia four weeks previously. Lanzani and Docimo also report instances.

We bring forward a case which illustrates neatly the mode of infection via the blood stream. The patient was admitted to Mill Road Infirmary on the first day of her acute illness, suffering from a Type II. pneumococcal pneumonia. Type II. pneumococci were isolated from the blood. Desperately ill, the patient was treated with serum and she recovered from the pneumonia; an acute thyroiditis developed five or six days after the onset of the pneumonia, progressing to abscess formation. The abscess was

eventually incised, Type II. pneumococci were grown from the pus, and the patient slowly recovered.

Miss A, a nurse aged 53, was admitted to Mill Road Infirmary on Nov. 9th, 1935. She had been aware of an adenomatous swelling of the thyroid for at least eleven years, and eight years previously, owing to symptoms of pressure on the trachea and œsophagus, the right lateral lobe and the isthmus had been enucleated at operation.

The morning of the day of her admission to hospital, she had felt an acute pain at the base of the right lung, aggravated by deep breathing; she vomited twice; she had a short painful cough, dyspnoea, and some cyanosis. The temperature was 103° F., there were signs of early consolidation at the base of the right lung, and rhonchi were heard over both lungs. She looked desperately ill and "toxic," and she was immediately given 20,000 units of Type I. pneumococcal serum and 20,000 units of Type II. serum. Meanwhile 10 c.cm. of blood was taken for culture, and after 36 hours Type II. pneumococci were isolated by Dr. H. A. Osborn. The morning after admission the same dose of mixed serum was repeated, and the general condition improved a little. On the third day there was herpes of the lips, blood-stained sputum was coughed up, and a film taken by the portable X ray unit confirmed the presence of a right basal pneumonia. It also showed a shadow filling the superior mediastinum, and pushing the trachea over to the right—a retrosternal prolongation of the adenomatous thyroid swelling. For a day or two the temperature hovered between 98° and 100° F., and the patient seemed much better. On the fifth day, however, the temperature rose again to 101° F. and then to 102° F. The following day she complained of pain over the upper part of the chest in front, and the cyanosis increased; only the front of the chest was examined, rhonchi and coarse moist sounds being heard over both lungs.

The outlook appeared so grave that a note was made about her testamentary capacity. Atropine and oxygen were given, and a further 20,000 units of Type II. pneumococcal serum were injected intravenously. While the serum made no difference to the temperature, the general condition improved slightly. The next morning she complained of severe pain over the left side of the neck, brushing her hand continuously and distressfully across the front of the neck. Extension of the neck made the pain worse, and she kept her head bent forward on the chest. She felt a "choky feeling," but could swallow fluids reasonably well. The dyspnoea was still severe. Now there was some dilatation of the superficial veins over the neck, and the thyroid swelling was larger. It was difficult to detect any movement of the gland with swallowing. The next day it was larger still, with obvious redness of the skin over it. Her condition, however, was better, and after consultation with Mr. S. V. Unsworth, the visiting surgeon, it was decided to wait to see if fluctuation developed. During the next ten days she slowly improved; Mr. Unsworth then aspirated about 30 c.cm. of green pus from the now fluctuating thyroid abscess. This pus contained Type II. pneumococci. Two days later Mr. Unsworth incised the abscess transversely and released a copious discharge of pus, leaving in a small rubber drain. The temperature began to subside and she made slow progress to recovery. She was eventually discharged from hospital on Jan. 29th, 1936; a radiogram of the chest then revealed complete resolution of the basal pneumonia and the marked displacement of trachea and œsophagus to the right side by the substernal thyroid mass.

Seen again on Feb. 24th she was well, save for obvious symptoms of pressure on the trachea and œsophagus. In view of the recent inflammatory reaction and scarring which must have taken place around the thyroid, it is not considered advisable at present to attempt the difficult task of operative removal of the substernal mass.

In the early stages of inflammation of the thyroid the process is confined within the tough capsule of the gland, and any fluctuation in or even enlargement of the thyroid is difficult to detect because of the overlying muscles and fascial layers. It is clear,

therefore, that pain is likely to be an early symptom before there is any obvious inflammatory swelling. If the inflammation extends to the fascial layers, adhesions may form and tie down the gland so that it cannot move normally with the movements of swallowing. Moreover, extension of the neck will cause compression of the inflamed gland by the fasciæ and muscles and increase the pain. As the inflammation progresses, the enlargement of the gland may produce pressure on the trachea and œsophagus, resulting in dyspnoea, perhaps a hard, dry, irritating cough, and dysphagia. The spread of œdema to the larynx may give hoarseness; the overlying skin may eventually become a little œdematous, the superficial veins dilated, and finally redness of the skin may indicate the underlying inflammation. Occasionally the abscess may burst into the trachea, and pus and blood be coughed up. Obvious fluctuation in the neck is a late sign. Rarely the symptoms of toxic goitre may supervene. Once the inflammation has extended outside the thyroid capsule, there is danger of the formation of a deep cervical abscess, with extension downwards to the mediastinum.

#### SUMMARY

A case is described of acute suppurative thyroiditis in a woman of fifty-three who had had a long-standing adenomatous goitre; it developed some five or six days after the onset of a Type II. pneumococcal pneumonia; Type II. pneumococci were isolated from the blood. Type II. pneumococci were grown from the pus obtained from the thyroid abscess.

## THE INTRAVENOUS ROUTE

### A NEW METHOD AND APPARATUS

BY C. G. K. THOMPSON, M.B. Edin.

ASSISTANT MEDICAL OFFICER, THE BROOK HOSPITAL, WOOLWICH

In children intravenous medication always presents a problem, chiefly owing to their restlessness and fear. The repeated wriggings and twistings of the arm during injection dislodge the needle from the vein, and an annoying hæmatoma may result. There is a great temptation to hurry, but this is to be strongly resisted if undue risks of shock are to be avoided. I have therefore evolved a method to satisfy the following five essentials: (1) it is the least disturbing to the child; (2) it provides the easiest access to the vein; (3) it does not tire the operator; (4) it allows the fluid to be injected at a constant blood-heat; and (5) it is the least liable to be interfered with by the restlessness of the patient. The whole difficulty is in the apparatus in contact with the patient's arm. The aim is to get rid of as much weight as possible, but the 20 c.cm., or occasionally

50 c.cm., syringe hitherto in general use had to be detached from the needle in the vein, refilled, and reconnected. The weight of these syringes is considerable when filled, and the slightest movement of the patient's arm is enough to dislodge the needle from the vein. The operator's hand also adds tenfold to the inertia of the syringe, which is already rendered more unwieldy by having its piston fully withdrawn. The ideal, therefore, would be to have only the needle and no syringe in contact with the arm. This unfortunately is not always practicable, and I compromise by using a very small syringe, which acts only as a means of holding the needle while puncturing a vein and as a window to show the blood coming back through the needle. It was introduced to me by Dr. H. S. Banks, medical superintendent of the Park Hospital, Hither Green, and is known as the B. D. Kaufman Luer syringe.<sup>1</sup> Although the same size as a 1 c.cm. Record syringe, it differs in that the body has an extra nozzle or adapter fused to its side about  $\frac{3}{4}$  in. from the needle nozzle. When the piston is drawn back it uncovers this second nozzle and thereby acts as a valve. The piston is chained to the body of the syringe, and this prevents withdrawal of more than an inch altogether. The whole syringe is very light and easy to manipulate, being long enough to control the direction of the needle while entering a vein; special needles with a Luer base and a medium acute bevel are used.

As this apparatus has been chiefly used for administering large intravenous doses of diphtheria anti-toxin and of dextrose, it will be assumed that the patient is suffering from the toxic type of faucial diphtheria.

Besides the Kaufman syringe, the apparatus is composed of a 100 c.cm. Pyrex all-glass syringe to act as a reservoir, two pieces of  $\frac{3}{16}$  in. rubber tubing, and a glass insert. The serum is placed in a water-bath at about 110° F. One piece of the rubber tubing 3 in. long is slipped over the nozzle of the 100 c.cm. syringe, which has been previously oiled with liquid paraffin and sterilised by dry heat. An adapter is connected to the distal end of the rubber tube and inserted into a cannula. The ampoules should now be opened. Before drawing up the serum, 10 c.cm. of air is drawn into the syringe first, and when the last ampoule has been emptied another 10 c.cm. of air is allowed to enter, with the nozzle held vertically. The rubber tube is removed and replaced by the other piece, which is about 15 in. long and has the glass insert at one end; the short piece is used to connect the side nozzle of the Kaufman syringe to the glass insert (Fig. 1).

FIG. 1.—Apparatus for intravenous therapy.

One hand holding the big syringe vertically, piston-head up, the other takes hold of the small syringe in such a way that its piston is fully drawn back, when it will be noticed that the serum, by the weight of the piston in the big syringe, will pass down the tube through the glass insert and up into the small syringe. To avoid bubbles of air during the injection, syringes are alternately raised and lowered. When all the air has been

expelled from the tube, the serum is allowed to enter the small syringe until a bubble of air, the size of a small pea, lies near the needle base; this is gently expelled by pushing the small piston, which by this action should have just, and no more, closed the aperture of the side nozzle, cutting off the supply. The 20 c.cm. of air is left

in the big syringe to act as a cushion between the piston and the serum, and so that the last drop of serum can be expelled from the tubing, which holds about 7 c.cm. The apparatus is now ready for use. On entering a vein the intravenous back pressure is transmitted to the piston of the small syringe, which moves back uncovering the side nozzle, and the serum starts to flow into the vein. Meanwhile the big syringe is held up by a nurse so that the delivery tube rests in a kidney dish of water at 110° F., and until the operator has fixed the small syringe to the forearm with two pieces of strapping—one over the needle butt, and the other over the body of the syringe immediately behind the side nozzle. The operator can now take the big syringe and control the rate of injection, the temperature of the serum being kept constant by having the delivery tube in the water-bath.

If the small syringe is securely fixed to the arm it will not be dislodged by sudden movements, and forcible restraint of the child is not necessary, but merely limitation of the range of movement. So unaware is the child of any discomfort that he often goes off to sleep and is only aroused by the removal of the plaster after the injection is completed.

This apparatus was used over three hundred times in the Brook Hospital last year to give injections of serum and glucose in amounts varying from 50 c.cm. to 100 c.cm. and alarming symptoms were never encountered. I attribute this mainly to the freedom from anxiety and apprehension about the needle coming out, which enables one to slow down the rate of injection with impunity.

#### A Calorifier

The usual method of keeping blood or other fluid for transfusion at proper temperature requires considerable and unceasing work for the assistant. However often the water-bath for the reservoir is changed, there is always some variation in temperature. A water-bath for 500 c.cm. of saline or blood must be kept at 130° F. for the patient to receive it at 100°–101° F. The heat loss is increased in the gravity-flow method because about four feet of rubber tubing is used. With regulated pressure flow it is less, owing to the smaller amount of tubing, but the constant attention needed makes the method a complicated one. On the other hand, the gravity feed requires no attention and the transfusion can be prolonged to diminish the risk of shock; there is however the one drawback, of temperature regulation, and I have attempted to lessen this by devising a calorifier.

It consists of a vacuum flask, a spiral piece of  $\frac{3}{16}$  in. bore pyrex glass tubing, a thermometer, and two pieces of ordinary glass tubing fitted to the rubber bung of the flask, as shown in Fig. 2. The spiral alone forms part of the conduit to the vein, and must therefore be boiled before use. To avoid breakage it is made inseparable from the bung. The spiral is made of glass to enable one to see if it is clean, and also to be sure of eliminating bubbles of air. The vacuum flask gets rid of the main cause of heat loss, but there is still some loss owing to the absorption

FIG. 2.—The calorifier.

<sup>1</sup> British agent, C. F. Thackray, 252, Regent-street, London, W.1.

of heat by the fluid passing through; to compensate this the other two tubes are fitted (Fig. 2). Tube A is connected to the suction end of a Higginson syringe, and B by rubber tubing to a convenient source of hot water at about 180° F. As soon as the temperature drops 5° from 110° F. on the calorifier thermometer, a light squeeze of the Higginson bulb will suck some of the cool water out from the top of the flask, at the same time drawing in hot water at the bottom to replace it. When the blood or saline is flowing at the rate of 90 drops a minute, the temperature in the flask drops at the rate of 1/2° F. a minute, so that, roughly, the temperature will have to be adjusted every ten minutes. Further, by connecting the calorifier in the circuit as near to the needle as possible, the radiation from the rubber tubing can be made negligible: the length need not be more than 24 in. The apparatus may be hung near the patient, or laid on the bed.

The calorifier has been used frequently, and found to work perfectly with the minimum of trouble and attention. The apparatus has been made for me by Messrs. Down Bros., London.

### PROGNOSIS OF RESECTION IN CARCINOMA OF THE STOMACH

BY WILLY ANSCHÜTZ, M.D.

PROFESSOR OF SURGERY AND DIRECTOR OF THE SURGICAL CLINIC IN THE UNIVERSITY OF KIEL

#### (1) CAN GASTRIC CARCINOMA BE DIAGNOSED EARLY ?

WHEN a patient comes to his doctor on account of gastric symptoms and has a carcinoma in the stomach it is our experience, and that of very many radiologists, that the carcinoma can be shown with almost absolute certainty by X rays. At all events, the X ray picture is not a normal one. Further, in our experience 94 per cent. of gastric carcinomas have occult blood in the stool. Even the smallest carcinomas are already ulcerated and, in consequence of the angioplastic reaction of the tissue, continually excrete blood. Carcinomas the size of a lentil (Versè, Konjetzny) have been found already ulcerated. *A normal radiogram and the absence of occult blood make the presence of a carcinoma improbable in the highest degree.* Then we do no diagnostic laparotomy. From the accompanying Table may be seen precisely what in the clinic here is regarded as the indication for intervention.

#### Scheme to Illustrate the Indication for Intervention

—	Occult blood.	Radiogram.	Probability of carcinoma.	Treatment indicated
1	Pos.	Typical filling defect.	Very probable.	Immediate operation.
2	Pos.	Uncertain.	Doubtful.	Diagnostic laparotomy.
3	Pos.	Normal.	Very improbable.	Keep under observation.
4	Neg.	Normal.	None.	—
5	Neg.	Uncertain.	Improbable.	Consider diagnostic laparotomy.
6	Neg.	Pathological.	Almost to be excluded.	„

In order to test the trustworthiness of this method of diagnosis I have re-examined, after a period of 2 to 15 years, all the gastric cases in which the diagnosis was not made certain by an operation. These are cases which were discharged unoperated with the diagnosis gastritis, adhesions, simple ulcer, suspicion of ulcer, ectasia, ptosis, and so forth. In a total of 375 such cases only 4 have been discovered in which what was certainly a carcinoma developed later. Reinvestigation of these cases has however shown

that in all four of them the radiogram was not quite normal or was not sufficiently exact, for in two cases the fundus in which carcinoma later developed had not been examined. I am convinced that a gastric carcinoma, even when it gives rise only to general symptoms such as pallor, wasting, or debility, can be diagnosed.

#### (2) ARE THE SO-CALLED EARLY DIAGNOSES ALSO EARLY IN THE SENSE OF TUMOUR GROWTH ?

That is difficult to say; for it is not a question of the size of the carcinoma but of the reaction of the body to it whether the carcinoma gives rise to metastases early or not. In regard to the duration of the symptoms and the possibility of resection, for over thirty years I have repeatedly found the following almost paradoxical relation—and this is true not only for the material of the Kiel clinic but also of that at Breslau and Heidelberg. As a rule the relation has been much as follows:—

#### Relation of Duration to Operability

Out of 1000 cases with duration of symptoms in months } ..	3	6	12	More than 12.
The tumour was capable of removal in.. ..	27	29	28	30 per cent.

That is to say, the duration of the symptoms before operation plays no perceptible rôle in the possibility of removal of the tumour and therefore of cure. Even when the cases are arranged according to the site of the tumour (pylorus or fundus) the operability does not alter in relation to the duration of symptoms. Probably a still better proportion of operability and operative results would be obtained if it were possible to resect earlier in the cases with longer anamnesis, but even that is not certain. I return to this point when I speak of the later outcome of resection.

#### (3) DOES EARLY DIAGNOSIS ENSURE THE HOPE OF RECOVERY ?

The answer to this, which is the main question, may be deduced from what I have already said. The question can, I think, only be answered with a conditional Yes. The problem of the cure of carcinoma lies on the biological side. If the carcinomas are divided into three groups, as shown in the Figure, the astonishing fact comes to light that the very small and easily operable carcinomas, in which when the operation is finished the surgeon is satisfied that a good result will follow, do not actually do better than the big adherent carcinomas in which operation is difficult. Naturally the immediate operative mortality of the first group (small tumour: no adhesions) is much smaller, latterly only 15 per cent., than that of the second group (large tumour: dense adhesions) where it is 30 per cent.; but once the operation is over the two groups have about the same prospect of cure—the second group indeed somewhat better! It almost seems as if the carcinoma which has called forth a severe local reaction and has invaded neighbouring tissues is less dangerous than the small non-adherent growth which gives rise early to distant metastases.

The mortality of the resection itself depends entirely on its extent and on the patient's general condition. In my clinic the total mortality has not fallen materially in recent years because we have continually widened the indication for resection. The proportion of resections has risen from 26 per cent.

in 1908 to 58 per cent. in 1933. Of the 183 cases in Group I. 18 per cent. died; of the 102 cases in Group II., 37 per cent. died, or, including stomach-colon resections, 44 per cent.; of the 145 cases in Group III., in which carcinomatous glands or metastases in omentum and peritoneum were left behind, 31 per cent. The considerable increase in these merely palliative resections continually prevents any fall in mortality. Besides that we have continually pushed up the age limit of operation. In the last five years 44 per cent. of our patients were over 60 years old, against 26 per cent. earlier. Under such circumstances it can hardly be expected that the general mortality of the resections should drop very much. With carcinoma before him the surgeon must resect whenever he can. That is shown by the figures of survival after palliative resection (Group III.).

Gastro-entrostomy we hesitate to do for gastric carcinoma. The average length of life after operation in 190 cases averaged six months. Only 6 undoubted cases of carcinoma survived more than a year. After palliative resection, on the other hand, 50 per cent. of the patients survived a year, 30 per cent. two years, and 20 per cent. three years. In considering the duration of the results in general and in the separate groups (see Figure) it must be borne in mind that

*Years of Life in Patients with Gastric Carcinoma Who Have Survived Resection*

GROUP I. (149 cases).—Uncomplicated cases with no adhesions: regional glands: regarded at operation as favourable.

GROUP II. (64 cases).—Severe cases: carcinoma firmly adherent: less favourable cases.

GROUP III. (99 cases).—Palliative resection: glands or metastases or carcinomatous tissue left behind: unfavourable cases.

Group III. shows in the first three years considerably more deaths than the other two groups. From then on the survival curves approach each other and from the fifth year on run almost parallel to the normal survival curve (N) for that age.

in a large number of the cases the patients are elderly folk. For comparison we have drawn in the normal survival curve (N) for the fifty-fourth year of age which corresponds to the average age of our resection cases (the expectation of life for each year can be obtained from the life assurance societies). From this it appears that five years after the operation the survival curve of the resections runs parallel with the average curve at that age. After five years there are 14 per cent. and after ten years 11 per cent. of cures, but on the other hand a certain number of cases relapse still later or a new carcinoma appears in the large intestine. I must emphasise that all the

surviving resection cases have been followed up. We were under the impression that the more freely growing carcinomas occurring with special frequency on the greater curvature did better than those infiltrating the pylorus and smaller curvature, but even with the latter we can record results lasting ten years or more.

#### CONCLUSION

All in all, gastric resection must be recommended urgently in carcinoma, and the operation done as early as possible, even at advanced age. The prospects of cure are in fact materially better in the older patients than in the younger. Of those under 40 years 5 per cent. survived five years or more; of the 40-60 year old group 18 per cent.; over 60 years 28 per cent. The percentage of operable and of surviving cases among the total number of gastric carcinomas is certainly not large, but there remain quite a number of cases. In my clinic we have to do more radical operations for gastric carcinoma than for carcinoma of the breast. Attention should not be directed so much to the hopeless cases which are not to be cured by resection as to the considerable number in which resection can be done with prospect of survival for long years.

## Clinical and Laboratory Notes

### TUBERCULOSIS TREATED WITH MERTHIOLATE

BY D. P. LAMBERT, M.D. Edin., D.T.M. & H.  
CAPTAIN, INDIAN MEDICAL SERVICE

In the Medical Research Council's annual report for 1933-34 (p. 61) it is stated that "the synthetic antiseptic known as 'merthiolate' has been found to be particularly effective" in killing the tubercle bacillus, with very slight effects on its antigenic properties. There is no suggestion in the report that it has any specific action on *B. tuberculosis*, and I certainly am making no such claim. The makers, Eli Lilly and Co., describe the drug as "sodium ethyl mercurithio-salicylate," and present it in a 1/1000 solution. In a healthy male volunteer, weighing 11 stones, ten intravenous injections of 10 c.cm. on alternate days produced no toxic effects and the drug was then used in hospital.

CASE 1.—Female, Mohammedan, aged 19. Was admitted for tuberculosis of the metatarsal bones with sinus formation, but was found to have extensive tuberculosis of both lungs. The sputum contained tubercle bacilli and the temperature swung daily from about 97° to 102° F. Malaria was excluded. The patient was treated on general lines for ten days with no improvement. On the eleventh day 5 c.cm. of merthiolate was given intravenously, followed by a like dose on alternate days up to six injections. The patient then discharged herself. After the second injection the temperature showed an unusual reaction, becoming stabilised round 100° with a daily range of not more than 2.5°. There were still tubercle bacilli in the sputum and the physical signs were unchanged.

CASE 2.—Male, Hindu, aged 33. Admitted for left-sided pleurisy with effusion of two months' duration. The effusion reached almost to the clavicle and was causing great distress, which the aspiration of four pints of fluid relieved. But absorption of the remaining fluid was slow and was not accompanied by reduction of the temperature which ranged from 99° to 102° F. Tubercle bacilli were absent on repeated examinations, and after six weeks injections of merthiolate were started, with

5 c.cm. intravenously on alternate days. After the second injection the temperature became normal, and it was still normal when the patient left hospital on the following morning.

**CASE 3.**—Male, Hindu, aged 37. Admitted for bilateral pulmonary tuberculosis, with extensive cavitation, and intestinal tuberculosis. Tubercle bacilli were plentiful in the sputum, and the patient was very wasted. His temperature swung irregularly from 97° to 101° F. with peaks up to 103° occasionally. Merthiolate injections, 5 c.cm. intravenously on alternate days, were started on the seventh day. Four were given without the slightest effect, and the patient then died.

**CASE 4.**—Male, Hindu, aged 22. Admitted with a psoas abscess, for which he refused aspiration or any other active treatment. He refused to remain recumbent or wear a plaster. His night temperature was raised to 99° or 100° F., the morning temperature being normal or sub-normal. Ten days after admission merthiolate injections (5 c.cm. intravenously on alternate days) were begun. From the third injection onwards the temperature remained normal, but after the fourth the patient discharged himself.

**CASE 5.**—Male, Mohammedan, aged 33. Admitted with bilateral pulmonary tuberculosis. Tubercle bacilli were found in the sputum, and there was a medium-sized cavity at the right apex. The temperature swung irregularly from about 99° to 103° F. Merthiolate injections (5 c.cm. intravenously on alternate days) were started on the seventh day, and continued till seven had been given, when the patient left hospital. After the third injection the temperature became stabilised round 101° F., the daily swing not exceeding 2.5°. Tubercle bacilli were still present the day before he left hospital.

**CASE 6.**—Male, Mohammedan, aged 13. Admitted with a cold abscess of the back, apparently arising from the ninth right rib. The abscess was aspirated and ordinary general treatment was carried out. The temperature ranged from normal to about 101° F., and despite repeated careful examinations no other cause than the rib tuberculosis could be discovered for it. The cold abscess responded well to aspiration, but the temperature remained high till the fifth week when injections of merthiolate (3.5 c.cm. intravenously on alternate days) were started. Seven injections were given, after which the patient's father removed him. In this case the temperature became normal after the third injection, but next day it rose again, remaining high for two days. Thereafter it remained normal. Seen again five weeks later this patient was apparently quite well, and had no fever.

**CASE 7.**—Male, Mohammedan, aged 25. Admitted with active bilateral pulmonary tuberculosis. There was no evidence of cavitation, but tubercle bacilli were present in the sputum. His temperature was 97°–102° F. On the eighth day injections of merthiolate were started. After the second injection the temperature was normal, but it continued to swing irregularly over about 2° round the normal line till he left hospital. By this time he had gained weight and said he was somewhat better.

**CASE 8.**—Male, Mohammedan, aged 36. Admitted for bilateral pulmonary tuberculosis, with a large cavity on the right side. The sputum contained many tubercle bacilli. The temperature swung from 97° to 103° F. On the third day 4 c.cm. of merthiolate was injected intravenously, and on alternate days doses increasing by 1 c.cm. at each injection were given till a dose of 8 c.cm. was reached. Supplies of the drug then became exhausted. After the third injection the temperature never rose above 101° F., but no improvement in the general condition took place. The patient discharged himself two days after the drug was stopped.

No toxic effects were seen in any case. All except Case 3, in which the patient was probably beyond human aid, showed reduction or stabilisation of the temperature after the exhibition of the drug, and in Case 7 there was also a gain in weight and subjective improvement. It remains to be decided whether the action of the drug (if any) on tuberculosis is merely

due to the antipyretic properties of its salicylate component. The best means of giving the drug and the optimum dose also need to be determined. Accurate controlled work is not possible in an Indian district hospital, and I hope that someone more fortunately placed will continue the investigation.

I am indebted to the inspector-general of civil hospitals, United Provinces, for permission to record these observations.

Saharanpur, U.P.

## A RAPID METHOD OF DRESSING INCISIONS

BY KENNETH MCFADYEAN, M.R.C.S. Eng.

THE device to be described is a firm but comfortable dressing that allows easy and painless access to closed operation wounds. The necessary materials, Elastoplast bandage and Rasco lightning bandage fasteners, are in common use.

First, cut two strips of 2 in. elastoplast bandage, each 2 in. longer than the incision to be covered. Lay one length adhesive side uppermost and cover  $\frac{1}{2}$  in. of its width with the protective supplied. Then

(a) The Elastoplast strips and the bandage fasteners. The dressing has been omitted for clearness. (b) The Rasco fastener.

fold the strip in half throughout its length and press the uncovered opposing surfaces firmly together. Finally remove the protective, separating the two non-adherent  $\frac{1}{2}$  in. faces and open them out at right angles to the remaining double thickness of bandage. Repeat this with the second length of bandage.

Now place one of these strips on each side of the incision, leaving  $\frac{1}{2}$  in. between the inner edge of each strip and the margin of the stitches or clips. Having applied iodine or other medicament to the closed incision, cover it throughout its length and 1 in. further at either end with a thick layer of sterilised gauze. This may now be held firmly in place by attaching two, three, or more rapid bandage fasteners to the free edges of the upstanding portions of the elastoplast strips. The whole dressing maintains apposition of the wound edges and relieves tension. The measurements given may, of course, be varied to suit individual cases.

Herne Hill.

UNIVERSITY COLLEGE HOSPITAL.—The authorities of this hospital are protesting against the proposal of the London Passenger Transport Board to convert Francis-street, University-street, and Huntley-street into a turning circle for the new trolleybus service down Tottenham Court-road. It is pointed out that an alternative turning circle could be provided via Euston-road and George-street or on the other side of Tottenham court-road.

## MEDICAL SOCIETIES

## ROYAL SOCIETY OF MEDICINE

SECTION OF OBSTETRICS AND  
GYNÆCOLOGY

At a meeting of this section held on May 15th, Dr. J. S. FAIRBAIRN presiding, a discussion took place on

## Induction of Premature Labour

Mr. A. J. WRIGLEY opened the discussion by proposing a motion that induction of premature labour should not play any part in the treatment of pelvic contraction or disproportion in primigravida.

## THE DANGERS OF INDUCTION

He started by recalling a conversation with a medical colleague who asked whether one could assess the fit of an infant's head into the pelvis and thus know when to induce labour. Mr. Wrigley's answer was that no one was capable of assessing this fit, or misfit, and even if it could be done it would serve no practical purpose, as one could not forecast the efficiency of the uterine contractions, the factor upon which ultimate success or failure depended. Few would advise induction of labour before about the thirty-sixth week of pregnancy, and if the disproportion was obvious before that date, most would agree that the choice, for the sake of both mother and child, would be delivery by Caesarean section. Was it possible to estimate exactly the dimensions either of the birth canal or of the size of the foetal skull? Could these two estimates if made be properly compared, and, if so, would such comparison be of advantage to mother or child? He thought the best purpose would be served if the debate were to revolve around the question whether we were satisfied with the results of our teaching or our individual efforts. During the last few years perhaps tens of thousands of unnecessary inductions had been performed, largely because the medical attendant had been led to believe that it was safer for the mother, and better practice in doubtful cases. Even in the teaching hospitals there was a great variation in the proportion of cases which were thought to need such treatment. In 1933, of 1070 booked cases in Birmingham Maternity Hospital, induction of premature labour for disproportion was regarded as necessary in 152, or 15 per cent.; in a further 28 (2.7 per cent.) booked cases, delivery by Caesarean section was necessitated by disproportion. On the other hand, in the Croydon maternity service during 1934-35 about 2500 were under care, and induction of premature labour was performed only twice, both cases being multipara. Caesarean section was done ten times (0.4 per cent.) in the same circumstances. These figures showed a very great divergence of opinion as to indications for induction in primigravida for disproportion.

Mr. Wrigley next sought to show that such wholesale interference was accompanied by a considerable risk and loss of life. The infant mortality in cases of induction of premature labour in primigravida in five years at St. Thomas's was 16.5 per cent., and at the General Lying-in Hospital, York-road, 17.5 per cent.; patients in those institutions were drawn from the same districts of London. At King's College Hospital figures showed that induction of premature labour by surgical means in primigravida resulted in a stillbirth-rate of 20.8 per cent. With

regard to maternal risks, F. J. Browne found that out of 173 deaths in nine maternity hospitals—all staffed by experts—5 per cent. followed directly on induction. In J. H. Peel's recently published series of cases 45 per cent. showed definite evidence of uterine infection after delivery. There was also a risk of severe haemorrhage, due to separation of the placenta. Moreover, after surgical induction the action of the uterus in labour was inadequate, and the complications of inertia were to be feared. Peel showed that induction of premature labour increased the forceps rate threefold. Mr. Wrigley held strongly that the surgical induction of premature labour in primigravida was unjustifiable, and that it was not possible to estimate the fit of a foetal head into the pelvis. Better results were obtainable by other means.

Mr. FREDERICK ROQUES spoke of the "other means" mentioned by Mr. Wrigley. Caesarean section was admittedly called for in dwarfs, rachitics, and women with grossly malformed pelvis. In others, except very rarely, it was impossible to foretell, early in pregnancy, whether disproportion would become evident by term. At about the thirty-sixth week a clinical examination should be made to determine the presentation of the foetus. This discussion would be confined to the cases in which there was presentation of the vertex. The relation of the head to the pelvis should first be determined; it would either be (1) engaged, (2) engaging, or (3) floating. By *engaged* was meant that the greatest diameter of the head had passed through the pelvic brim, so that it was firmly fixed and less than half the head could be palpated abdominally. Normal labour could be anticipated when it was found that the head was engaged at this stage, for contraction of the bony outlet was not, in his experience, found apart from contraction in the other pelvic planes. Neither Mr. Wrigley nor the speaker believed that it was possible accurately to measure the outlet, and even if it were the clinical position would remain unaltered, because the head diameters could not be measured. By an *engaging* head was meant one lying low in the uterine cavity with limited mobility on abdominal palpation, though its widest part was not yet past the brim; more than half the head could be palpated abdominally. In such cases further descent with engagement could be expected during the ensuing period before term. A head *floating* above the brim could be palpated abdominally over practically the whole of its surface. An attempt should be made, by the Munro Kerr or a similar method, to determine whether the head could be caused to enter the pelvic brim. If not, the patient should be treated expectantly, except in the presence of gross pelvic malformation or complicating factors, when Caesarean section should be advised. If the head could be pushed in or if overlap was absent, another examination should be made a week or two later; and a similar policy should be pursued if the clinical information elicited was uncertain owing to the tone of the muscles of the abdominal wall, obesity, or the patient's resistance to examination. Anaesthesia would overcome these interferences, but should not be employed at the thirty-sixth week. Mr. Roques would therefore say that all cases except those with gross pelvic malformation or complication at the thirty-sixth week should be treated expectantly, and re-examined at a time nearer to term.

The methods of investigation available were:

(1) X rays, (2) clinical methods, including examination under anæsthesia. The first of these could be of great value if done by expert radiologists working with the best apparatus. As a result of those two methods of investigation a case fell into one of the two groups mentioned; that in which the disproportion was pronounced, and that in which disproportion was either absent or slight. The great majority of cases belonged to the latter group, and should be submitted to a trial labour. Some might argue that an almost exclusively expectant policy amounted to a confession of ignorance on the part of its protagonists, but he affirmed that no obstetrician could accurately foretell before labour commenced how a case would progress during labour.

Mr. ARNOLD WALKER said that it was unwise to induce premature labour with a view to avoiding mechanical trouble in primiparæ, because of the frequency with which induced labour was complicated by inertia, and the proportion of cases in which the child died. His experience was at the Willesden Maternity Hospital, where the patients were a representative lot, embracing those coming into an expanding industrial district from all parts of the kingdom; those of whom he spoke were under his personal care, a fact favourable to accurate analysis. In 1447 primiparæ there were only 18 (or 1 per cent.) in which the child failed to work its own way out. Cæsarean section was done 13 times, and all the mothers and babies did well. In only 9 of the 13 was the operation done because natural delivery at the time was not likely to result in the birth of a live child. In 6 the size and shape of the pelvis was the only indication for operation. The number of patients in his series who were not allowed to go into labour spontaneously was 6; those in whom the labour was terminated by Cæsarean section because it was feared a live baby would not be delivered numbered only 3. With regard to the meaning of the term "trial labour," his conception was not that of a battle between the fetal skull and the bony pelvis in which it was hoped that the skull would be defeated before the uterus gave up its efforts; he and his colleagues regarded it as the provision of an opportunity for a deflexed head or a conical uterine segment to right itself, and for the increased tension on the ligaments to pull down the uterus and its contents. When time had been given for readjustment the position could be reviewed afresh.

#### IN FAVOUR OF INDUCTION

Dr. HERBERT SPENCER, who opened against the motion, reminded members that five years ago when the section debated this subject there was a general acknowledgment by the participants—including Mr. Wrigley—of the value of the induction of premature labour for minor degrees of pelvic contraction or disproportion. At that date only one hospital (London Hospital) had ceased to practise induction. Though the present discussion was restricted to primiparæ, Dr. Spencer saw no reason for the limitation. The value of induction could only be estimated if full particulars of alternative methods of treatment—i.e., trial labour, forceps, Cæsarean section, craniotomy—were given, with the total deaths of mothers and children. Dr. Spencer's own use of forceps had been conservative since, 46 years ago, he learned that all the children delivered by forceps who died showed meningeal or cerebral hemorrhage. He gave the following particulars of induction and other methods of treatment during the last five years of his service in University College Hospital—

namely, 1920 to 1924. Induction for contracted pelvis ( $3\frac{1}{4}$  to  $3\frac{1}{2}$  true conjugate) was carried out in 85 primiparæ and 128 pluriparæ, 1 mother and 25 children dying. Cæsarean section for contracted pelvis was carried out in 56 cases with no maternal mortality; 2 children died. Craniotomy (3 for dead children, 2 for hydrocephalus) was carried out in 5 cases, with no maternal mortality. One maternal death from sepsis after induction was the only fatality in a consecutive series of 427 cases at the hospital, showing a mortality-rate of 2.3 per thousand, while the foetal death-rate was just under 12 per cent. Of the 85 primiparæ of this series, 10 children died, or 11.7 per cent. Only full details of all the cases treated by individual obstetricians would enable a due estimate to be arrived at as to the value of induction in the treatment of contracted pelvis. Induction had the great advantage over alternative methods that it usually did no harm to the mothers; indeed, the harm was less than in a natural labour. His opinion, therefore, was that in the treatment of cases of minor contraction or disproportion, induction should play a large part, Cæsarean section and forceps delivery a small part, and craniotomy (except for dead, damaged, or hydrocephalic children) no part whatever.

Mr. JAMES WYATT said that he and those who thought with him were only out to induce labour in a patient with a small pelvis if it seemed unlikely that the head would pass through. In a trial labour the patient was allowed to have a reasonably long second stage, in order to ascertain whether the head would go through; if it did not, Cæsarean section was performed. In all labours there were two variable factors: the strength and frequency of the pains and the size of the foetus. With regard to the idea that the pains after induction of labour were poor, much depended on the means adopted to induce labour; the pains were just as poor in patients who entered labour naturally, especially if the head was high up. Frequently the fetuses of primigravidae weighed  $8\frac{1}{2}$  to 9 lb. Risks to the infant were increased by a prolonged labour. Some of the cases after a long second stage in a trial labour would have to have a Cæsarean section, an operation which, in Mr. Wyatt's view, was carried out too often and with too little weighing of consequences, both immediate and remote. If there was a demand for so-called trial labour it should be in a second labour, when certain factors were already known. The maternal passages had already been dilated by the first infant, so the amount of force necessary to overcome resistance for subsequent ones was lessened. He felt that the anti-induction school had arisen because Cæsarean section had been treated too lightly. In one large provincial hospital Cæsarean section was performed 158 times in 2401 cases. If induction had been carried out he thought a large proportion of those babies would have been alive, and the uterus would have borne no scar.

#### GENERAL DISCUSSION

Dr. EVERARD WILLIAMS based his contribution on cases under his care at Charing Cross Hospital and at the Ilford Borough Obstetric Hospital. In the antenatal examination of an expectant mother, the general inspection of her bodily frame would indicate to which type she belonged, whether of the asthenic type with a flattening of the brim of the pelvis, or the sthenic type, in which the pelvis as a whole approximated to the male configuration. Foetal deflection was physiological until the forces

of labour set in to promote flexion. He regarded disproportion at the brim as the rarest, not the commonest, cause of the floating head. In 3714 deliveries at Charing Cross Hospital there were 187 surgical inductions for disproportion, 17 (9 per cent.) fetal deaths, and 1 maternal death (due to pulmonary embolism). At Ilford in 4301 deliveries there were 200 surgical inductions, 21 fetal deaths (10.5 per cent.), and no maternal deaths. The Ilford figures showed the maternal morbidity in the cases of surgical induction to be lower than that for the whole series of over 4000 births; this surely suggested that surgical induction, if properly carried out, was a safe procedure. The fascial supports of the pelvic organs arose from the white line of the pubes and the bone about the ischial spine. The extensive trauma inflicted on them, causing retroversions and prolapses, supported the view that it was not in the region of the brim, but in that of the cavity and outlet of the pelvis that disproportion really existed.

Mr. S. GORDON LUKER said that the general indications for the induction of premature labour were a slight or moderate degree of contracted pelvis in which the true conjugate was estimated to be not less than  $3\frac{1}{2}$  in. The fœtus should be not more than four weeks premature, as its chances of survival before this time were not sufficiently favourable. If the patient was examined at frequent intervals towards the end of her pregnancy the correct time for induction could be arrived at. The examination should include the umbilical girth of the mother, the height of the fundus uteri, and a thorough palpation to judge of the size of the fœtus. If the fœtal head could not quite be pushed into the brim of the pelvis by abdominal examination, the bi-manual method must be used, if necessary under anaesthesia. Induction was free from risk, in his view, if carried out in a proper manner. The aseptic ritual must never be relaxed. Owing to the softness of the fœtal head, forceps must not be used if that could be avoided; as the fœtus would not be as strong as a full-time child a prolonged or deep chloroform anaesthesia must not be given. He gave particulars of 110 cases under the care of Dr. J. C. Norman and himself, in which 3 infants were stillborn, and 1 died on the seventh day after delivery (less than 4 per cent.). His conclusion was that induction of premature labour was a most valuable procedure in many cases, preferable to a test labour. The increasing demand for analgesics, especially among educated women, militated against test labours, and so the alternative of Cæsarean section was carried out. The latter was a major operation, not so safe as labour after induction by bougies. The fertility following Cæsarean section was considerably diminished and moreover a subsequent pregnancy involved the risk of rupture of the uterine scar which occurred in 4 per cent. of cases.

Dr. J. C. NORMAN, speaking as a general practitioner, was still an enthusiast about induction of labour. In several cases known to him Cæsarean section had prevented women from having any more children. He had carried out premature induction not only in institutions but also in private, and as he had had no bad results he felt justified in regarding it as a safe procedure.

Mr. G. W. THEOBALD said that one of the things which had emerged from the discussion was that the particular method was of less importance than the man behind the method. Another feature was the revolt against Cæsarean section, an attitude with which he cordially agreed. He quoted with approval Fitz-

Gibbon's view that to speak of "trial labour" before the membranes had ruptured was a contradiction in terms. There was no antithesis between trial labour and induction of labour. If one wished to prevent forceps delivery and a long labour one must start at the beginning of the first stage of labour, and not concentrate on the second stage; valuable drugs for this purpose were quinine, morphine, and hyoscine.

Prof. MUNRO KERR remarked that in no other country could such a discussion as this take place, since in no other country was it thought advisable to induce labour in cases of contracted pelvis in primiparæ. It was impossible in borderline cases at the thirty-sixth week to tell whether the fœtal head would or would not go through. Adjustments might take place during the last period which completely altered the relative sizes of head and pelvis. A point not referred to in text-books was that when the examiner grasped the fœtal head above the pelvis, the patient lying flat on her back, he was apt to tilt it either forward or backward, and so to produce either anterior or posterior parietal obliquity. One could not possibly tell beforehand how the head would mould in labour, nor what would be the strength of the uterine contractions. Prognostication was only safe after labour had commenced. Obviously, therefore, in primiparæ the only reasonable course was to allow the patient to go into labour. At that stage, however, he contended that he could ascertain, within 10 per cent. of error, whether a particular head would go through. The sooner the induction method in primiparæ was banished the better.

Mr. HASTINGS INCE spoke of a series of 9762 deliveries at University College Hospital, in which there were 144 surgical inductions for contracted pelvis or disproportion. The gross fœtal mortality-rate was 11.4 per thousand. In one-third of the cases forceps had been used. His conclusion was that induction of premature labour had a place in obstetrics. Every subsequent pregnancy of a woman must be regarded afresh.

Mr. ALECK BOURNE said he had not carried out induction of labour since, in 1924, Whitridge Williams said he never did it. In the present discussion too much stress had been laid on the factors of the size and weight of the baby. Induction was done in order to obtain a smaller head; measurements showed that the reduction of the presenting head obtained by inducing at 36 weeks was not more than one-third of an inch; and he doubted whether it was worth while to interfere with pregnancy and induce labour for that small reduction. The serious argument against induction in disproportion was that the second stage of labour was too easy; too much stress was usually laid on mechanics. The quality of the contractions might change a case, and he agreed that one could not always predict the quality of pains. Induction of labour was dangerous; it was the chief aetiological factor in inertia. The mortality of inertia lasting more than 48 hours was 10 per cent., and in 28 per cent. of cases induction played a part in its aetiology.

Mr. A. L. GUNN spoke of his work at Croydon, where he handled 1300 cases a year. All who brought forward series of cases should state whether or not they were selected. In 2100 deliveries surgical induction was carried out in 2, both in multigravidæ. In 1103 second pregnancies surgical induction was not done at all. Cæsarean section for disproportion had been done in 5 cases and no craniotomies had been done.

Mr. W. R. WINTERTON spoke of 44 cases at the

Middlesex Hospital in ten years in which surgical induction for disproportion was carried out. The average length of the first stage of labour was 28 hours. There were 38 per cent. of primary inertias, and 22 per cent. lasted more than 48 hours. The forceps rate was 18 per cent.; in 15 per cent. of cases sepsis occurred, half of them following forceps delivery. There were 6 stillbirths, one of them macerated. Half of the cases were delivered by forceps.

Dame LOUISE MCILROY said that she had largely given up induction of labour, not because results were bad, but because the results which followed the policy of leaving the patients alone were as good, if not better. She did not see the need for so much criticism of trial labour, since every labour was, in a sense, a trial. One of the reasons why she had discontinued induction of labour was that having introduced a foreign body into the uterus, one had shot one's bolt. It was bad practice to use forceps thereafter; there was the added risk of sepsis, and Cæsarean section was out of the question. She did not think enough stress had been laid on the ligaments. What mattered was the "give" of the pelvis, combined with the relaxation of the soft parts, and the contractions of the uterus. Treatment preliminary to labour was useful. In the last week of pregnancy grs. 15 of chloral every night made a vast difference in the character of the labour; as also did sitz baths.

Dr. DOROTHY LOGAN commented on the different standard conjugates found in different parts of the country, and hence the fallacy of conclusions based upon an idea of a standard normal conjugate everywhere.

Mr. WILLIAM GILLIATT ranged himself on the side of the supporters of the motion. Since the beginning of January, 1932, he had not done induction of labour in primigravidae. The change in method of treatment was forced upon the staff at King's College Hospital by the unsatisfactory results to mother and child which followed induction of labour. He and his colleagues there allowed all cases to have a trial labour on the lines suggested by Mr. Theobald; no so-called trial labour was such until the membranes had ruptured. There could be no regret at the change, as in the last five years their figures had been far better.

The openers briefly replied, and the vote on the motion resulted in 40 supporting it, and 18 opponents.

## TUBERCULOSIS ASSOCIATION

At a meeting of this association, held in London on May 15th, a discussion on

### Climate and Its Relationship to Tuberculosis

was opened by Sir LEONARD ROGERS. The immense importance of tuberculosis as a cause of illness and mortality in India was not, he said, yet sufficiently realised. Post-mortem examination showed that the type of disease was often that of chronic fibroid phthisis, healed pulmonary, and even intestinal tubercle being also frequently met with; all this indicated long tuberculation of the Indian races. As 15·8 per cent. of the deaths occurred before the age of 21, nearly all in adolescents, with another 36 per cent. in the third decade the type corresponded with that of Brownlee's "young adult" group which had been recently shown to be the type most influenced by climatic conditions. There was a good deal of evidence to show that damp hot climates are harmful

to tuberculous patients. It was essential, however, when studying the influence of any climatic factor, to deal with strictly comparable populations, such as rural ones living under the same conditions, or with very large and well-populated areas with widely varying climatic conditions, such as India furnished. The scanty evidence on the effect of soil and geological formation appeared to suggest that living on damp soils predisposed to increased phthisis. Any beneficial effects of high altitudes were in all probability due to such factors as lowered temperature, lessened rainfall and humidity, long hours of sunshine, and sheltered position, and not to any virtue in high altitudes in themselves. The late W. Gordon had shown that rainfall, apart from direct rain-bearing winds, had no close relationship to the incidence of phthisis in Devonshire. In India the speaker had found a very close general relationship between a high annual humidity and a high incidence of tuberculosis. In a few cases, however, notably in Assam, the tubercle rate was low, while the rainfall was heavy and the humidity high. Here another factor was involved—namely, the remarkable degree to which the province was sheltered from strong winds. Sir Leonard showed a number of maps marking the distribution of tuberculosis in relation to rainfall, humidity, and rain-bearing winds, illustrating his general conclusion, which the work of others in Europe and America had confirmed, that the climatic factors favouring high tuberculosis incidence were considerable rainfall accompanied by strong rain-bearing winds carrying a high degree of absolute humidity to the affected areas. Those affected with or predisposed towards tuberculosis should, when possible, seek a dry, sunny, cool place with fairly low rainfall and little wind, and protection from the directions from which the main rains came. A point of interest was that maps of the distribution of pneumonia in relation to climate in India, which Sir Leonard had prepared, showed precisely the opposite incidence to that of tuberculosis—namely, very high prevalence in the winter months in the North-West Frontier Province, Sind, and Gujerat, with a dry cold climate, the maximum diurnal variation of temperature of over 30° F., and winter absolute humidity of under 0·3; and the lowest rates in Madras and Lower Burma with the opposite climate in all respects.

Dr. ANDREW MORLAND said that variations in the tuberculosis mortality-rates in different parts of the world had very little connexion with the question of climate, owing to the fact that so many other factors were involved. It was important to keep constantly in mind the dictum of the late Dr. Huggard of Davos: "Whether a climate is bracing or relaxing depends mainly on the patient's power of response; for metabolism to be increased the digestive organs must be in good enough order to respond to a demand for increased activity of function." Although there were other important factors, such as the amount of sunshine, climatic treatment depended in the main on putting the patient in an environment which either stimulated or retarded his metabolism. The metabolic rate was increased by such factors as low temperature, wind, and dryness of the air, this last acting by facilitating evaporation not only from the surface of the body, but also from the lungs. But the fresh-air treatment of tuberculosis had suffered from excessive enthusiasm, and some of its advocates had gone too far in exposing to bitterly cold weather patients whose metabolism could not respond to such a strong stimulus either because they had been too much weakened by disease, or

because they were wrongly constituted for such rigorous treatment. The thick-set, or pyknic, type of person would as a rule be able to respond to a bracing climate in a way that the asthenic type could not do. After giving a short regional survey of various countries in different parts of the world the speaker went on to discuss the question of high altitudes in more detail. The special characteristics of such a climate were, that it was cool and dry, with low barometric pressure and high intensity of light, with a considerably greater proportion of ultra-violet rays. The low barometric pressure was a great stimulus to metabolism. Even at 5000 ft. the basal metabolic rate was increased about 20 per cent. To counteract the shortage of oxygen in the air, the red corpuscles increased in number, contraction of the spleen being the first mechanism called into play, which was followed by increased activity of the bone-marrow. The effect of altitude on the nervous system was of great importance. In general, highly nervous people did not stand altitude well, and tachycardia and insomnia were frequent complaints. Sufficient attention had not, he thought, been called to the fact that people who at first derived benefit from altitude sometimes got stale later on and needed a change. Speaking generally, in the majority of cases it probably made little difference whether the patient was treated in Great Britain or in the Alps, provided that he went to a good sanatorium where the discipline was strict. Early cases, especially when there were active symptoms, were, he considered, best treated at a low or moderate altitude where their metabolism would not be excessively stimulated. Afterwards a change to a higher altitude might often be an advantage.

Dr. G. B. PRICE said that the advantages to be derived from residence in sanatoria at high altitudes—over 4000 ft.—were undeniable, but they had to be balanced against certain disadvantages, such as increased expense, unfamiliar and often monotonous diet, lack of restrictions which might allow a patient to follow his own bent in appetite and indulgence, and the necessity for “declimatisation” on returning to English conditions. Moreover, the valuable physical and psychological effect of the pure stimulating air and increased sunshine was not necessarily accompanied by a corresponding improvement in the foci of disease. Alpine treatment could not provide a short cut to a cure, nor could even the most ideal climate replace the ordinary methods of treatment. Marine climates in tropical and subtropical areas also had their drawbacks. During the war Dr. Price had charge of a large hospital in Malta situated on the highest point of the island, where 300 beds were occupied by early tuberculous cases, mainly of those invalided from Salonica. Most of these cases did well only up to a certain point, after which it was highly desirable to get them back to England. For the bronchitic type of tuberculosis, as with bronchitis, emphysema and its complications, a low altitude, humid climate free from dust and a more or less uniform temperature, summer and winter, were assets of great importance, leading to improvement when ordinary measures were unavailing.

Dr. A. SANDISON said that the experience of the Ministry of Pensions, over an average of 20 years, in the treatment abroad (Switzerland and the Riviera) of over 300 tuberculous officers and nurses was instructive. The cases could be classified in three groups: (1) from 1919–1922, when the cases had not been subject to any special process of selection for such treatment; (2) 1922–1925, when, following on a survey by the Ministry of all the cases then

abroad in Switzerland and the Riviera, the Ministry increased its control and a much more careful selection was made of cases likely to benefit from such treatment; (3) 1925 and onwards, following on a second survey, when the control was further tightened up, and responsibility for such treatment only accepted by the Ministry when it appeared likely that the resulting benefit to the patient could not be obtained by treatment in this country. A research was now being made into the results obtained in these three periods, the groups being further subdivided according to their clinical types and to the locality in which the treatment was given—Switzerland, the Riviera, or both these. The clinical types were: (1) those patients in whom tubercle bacilli had at some time been found; (2) those with negative sputum in whom a clinical diagnosis of tuberculosis had been made; and (3) those whose pulmonary condition was primarily one of bronchitis or emphysema, with no definite evidence of tubercle. The investigation being still uncompleted, no final conclusions had yet been arrived at.

## ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

THE main discussion at the quarterly meeting of the Association, which took place at the Royal Mental Hospital, Glasgow, on May 13th and 14th, under the presidency of Dr. REGINALD WORTH, was on the subject of

### Somnifaine Therapy

Dr. A. MACNIVEN (Glasgow) discussed the clinical aspect. He said that as long ago as 1870 such drugs as ether, chloroform, alcohol, and certain derivatives of opium were used for the purpose of producing prolonged periods of unconsciousness in the treatment of mental disease. The first use of somnifaine to this end was by Klaesi in 1922, when he treated 24 patients suffering from dementia præcox in this way, and obtained definite improvement in many. Negativistic patients became much less resistant, and tube-feeding could be replaced by normal meals; moreover, some mute patients became fairly talkative. In this country the first trial was that by Dawson and Barkas at the Maudsley Hospital in 1926; they came to the conclusion that it was a dangerous treatment, entailing serious risk of death from cardiac failure. Certain other workers reported a high mortality from the method. Ström-Olsen evolved a method of combating by glucose and insulin the toxic symptoms produced by prolonged administration of somnifaine, especially the ketosis. He found that by giving glucose and insulin during the treatment, such symptoms as diminished glucose tolerance, tachycardia, circulatory collapse, suppression of urine, albuminuria, and certain disturbance of coördination were largely eliminated. In 15 patients who received glucose and insulin the dangerous symptoms disappeared in 48 hours or less; in 17 cases in which glucose and insulin were given throughout treatment, no serious complications occurred. Ström-Olsen and Muriel McCowan obtained very good results by treating 107 cases in this way, particularly cases of manic-depressive psychoses. In 49 cases in the schizophrenic group, 8 per cent. recovered, 38½ per cent. improved, and 53 per cent. were unchanged. In Dr. MacNiven's cases the somnifaine was injected intramuscularly in doses of 2 c.cm.; the degree of narcosis aimed at was that approximating to natural sleep; it was not difficult to

arouse patients sufficiently for purposes of feeding and excretion. The treatment was continued for ten to fourteen days.

**Complications.**—One woman died from pneumonia contracted on the first day of the treatment; it would be difficult to blame the somnifaine. In three cases there were symptoms of cerebral irritation, with some rise of temperature; in one of them there was probably calcium deficiency, for when she was given calcium by the mouth the symptoms completely subsided. In one male patient the temperature rose to 104° F. on the fourth day of treatment. He had marked leucopenia, and though the treatment was at once stopped, the narcosis lasted two more days. The treatment was not resumed. In three cases there were indications of circulatory failure. In only one case were there renal complications, the urinary output being dangerously low on the fifth day. With alkalis the renal symptoms disappeared, and the somnifaine treatment was resumed. In eight cases catheterisation was needed at some time. So far, in the Royal Mental Hospital, Glasgow, 20 men and 20 women had been submitted to the treatment; 25 of them were suffering from manic-depressive psychosis. In 5 of the cases recovery was definitely attributable to the treatment; 10 were permanently improved, 15 temporarily so, while 10 were unchanged by the treatment.

Dr. J. MACDONALD (Glasgow) dealt with the psychological aspects of the treatment. In view of the number of drugs which had been employed for inducing narcosis he considered that in seeking an explanation of the results obtained other factors than biochemical ones had to be taken into account. A rational explanation, he submitted, could be based on the psychological and physiological laws of habit and resistance. Prolonged sleep interfered with or inhibited for the time being habitual modes of thought and action, resistance to which in the normal wakeful state had been either weak or futile. This enforced period of quiescence enabled the patient to acquire new habits of thought and action, or rendered possible the better use of ideas already acquired. This change was likely to be especially pronounced in the schizophrenic. If at the right time the patient's interest could be aroused, and healthy thoughts encouraged, the physician could make good use of all the methods at his disposal.

Mr. J. H. QUASTEL, D.Sc. (Cardiff), dealt with the physiological and biochemical aspects. He said it would be a pity if such research as this were to be abandoned because of the considerable toxicity apparently associated with it; it was desirable to obtain some idea of how narcotics worked, while efforts were being made to reduce toxicity. It was necessary to realise that the main substance burned by the brain was glucose; the dominant form of metabolism in the central nervous system was associated with the breakdown of glucose and lactic acid. This could be proved by experiments on the living animal, or with brain tissue *in vitro*. It was scarcely possible to work on human brain, owing to the difficulty of obtaining it fresh enough. Glucose and lactic acid were necessary for the functioning of the nervous system, and it was those substances whose metabolism was inhibited by the narcotics. Ether in sufficient concentration to effect narcosis inhibited the oxygenation by the brain of sugar, but as the effect of ether was cumulative, and was not easily reversible, this was not a good substance to use in treatment. Glucose and insulin were useful because they combated the toxic effects of narcotics in

organs where the carbohydrate metabolism depended greatly on the glycogen-glucose metabolism.

Dr. W. M. FORD ROBERTSON (Glasgow) said that as early as 1882 Gessinger sought to allay the excitement and restlessness of his psychotic patients by prolonged ether and alcohol narcosis. Of the numerous types of insanity which had been subjected to prolonged narcosis, the acute forms, such as mania and the manic phase of the cyclic psychosis, were the most successful. The patient suffering from tetanus, who because of sepsis was in extremis, did not respond to the anæsthetic or narcotic, his nervous system and somatic functions being at a low ebb; and this might be the case, too, with many schizophrenics. In mania, deep narcosis if given at once acted mainly in the true phylactic sense. He thought protein shock might have a place in the therapeutic scheme if carefully controlled by observation on bone-marrow activity; he urged all workers in this field to follow closely the advances being made in the knowledge of brain metabolism.

Dr. P. K. MCCOWAN (Cardiff) said he had given 300 treatments of prolonged narcosis, 200 with glucose and insulin, without a death. He emphasised the importance of carrying out the treatment in a dark, single room; this gave results with smaller dosage than when the patient was exposed to noises and distractions which militated against both narcosis and natural sleep. If acetone in the urine was found to be increasing, the treatment was stopped. As the mental disorders from which the patients were suffering were not in themselves lethal, there was no justification in submitting them to a treatment which carried the possibility of death. For this reason it was imperative to carry out frequent urinary and other clinical investigations during the treatment. He had found that in a quiet and darkened room more than two doses of 4 c.cm. each were seldom required to induce narcosis to the point at which the patient could be roused for the usual physiological functions.

## SOCIETY OF RADIOTHERAPISTS OF GREAT BRITAIN AND IRELAND

A MEETING of this society was held in the rooms of the Medical Society of London on May 15th, Mr. G. B. STEBBING, the president, being in the chair, when a discussion took place on the technique and results of

### Radiation Treatment of Carcinoma of the Rectum

Miss M. C. TOD (Edinburgh) said that the treatment of carcinoma of the rectum presented so many difficulties that no one could approach the subject with confidence. Before the position of radiation therapy could be assessed it was necessary to consider the possibility of cure by surgery and she had therefore prepared a short review of the literature published during the last five years. It was clear that no really satisfactory solution to the problem had been found. There were three main operative procedures, the perineal excision, the abdomino-perineal excision associated with the name of Miles, and the perineo-abdominal excision practised at the Mayo Clinic. Radiation therapy included the insertion of intracavitary radium, combinations of surgery with implantation, and combinations of X rays and surgery or X rays and radium. None of these methods produced very good results. Coffey claimed 60 per cent. successes but could only treat half his

patients. T. E. Jones had 52 per cent. of operated cases alive after five years, and Lockhart Mummery gave about the same figures. As to radiation statistics G. E. Binkley, of the Memorial Hospital, New York, gave full treatment to 25 out of 238 patients seen and 13 of these survived over five years. The latest report of the Radium Commission recorded 15 out of 107 alive over three years. Miss Tod showed a table giving the results in all cases admitted to the Royal Infirmary, Edinburgh, over the last four years. Although these were fairly recent, it was already obvious that the survival-rate was not likely to exceed 10 per cent., a figure borne out by a report from the hospitals of Boston, U.S.A., giving an absolute survival-rate of 8 per cent. Miss Tod submitted that the Edinburgh figures provided a fair average for any general hospital, and claimed that the necessity for further investigation and trial of radiation methods was established.

The PRESIDENT said that he was fortunate in having experience of a large number of cases. He still believed that the genuinely operable case should be treated by excision, but if this was contra-indicated by the general condition, and in more advanced cases, the results recently obtained from thorough radiation therapy were distinctly encouraging. He gave a full course of X radiation including a perineal field; the patient sat on a chair fixed above the aperture of the tube with an applicator in such a position that careful compression allowed the growth to be brought considerably nearer the skin surface. He regarded as the main essentials for success (1) the arrangement of all his applicators as near the growth as possible, and (2) the very careful aiming of the beam. External

radiation was supplemented by intracavitary radium in a special applicator designed to hold the radium at a fixed distance from the mucous membrane. It was in his opinion always advisable to perform a colostomy in advance. The patient was much more comfortable during treatment, and even if the disease was eradicated a fibrous stricture remained and the artificial anus was inevitable.

Dr. N. S. FINZI (London) gave particulars of five patients treated by him with intracavitary radium who had survived for long periods, one for over 20 years. He believed that the possibility of such results should stimulate further inquiry.

Dr. J. T. REARDEN (Manchester) described the technique employed at the Holt Radium Institute which consisted now of the implantation of long needles (13 cm.) round the rectum to include the largest possible volume of tissue. At the same time intracavitary radium either in the special applicator or in sorbo rubber was inserted. The needles were left in position for 6-7 days, the applicator for about half that time. The treatment was now given on two occasions. The results though inconclusive were encouraging.

Dr. FRANGCON ROBERTS (Cambridge) described his method of external radiation which makes the greatest possible use of the surface skin and so obtains a high dose at the tumour.

Mr. B. W. WINDEYER (London) said that he had tried interstitial radium as a palliative measure and the results obtained had been surprisingly good. It was now his intention to attempt a combined treatment on a series of cases, a course in which the discussion had encouraged him to continue.

## REVIEWS AND NOTICES OF BOOKS

### Peroneal Type of Progressive Muscular Atrophy

By JULIA BELL, M.A., M.R.C.P. Being Part 2 of Vol. IV. of the "Treasury of Human Inheritance." London: Cambridge University Press. 1935. Pp. 140. 12s. 6d.

THIS able monograph fully justifies the title of the series under which it is published, being certainly a treasury of knowledge and research. One is tempted in contemplating the miserable stories of hereditary disease retailed in successive volumes to suggest that the tragedy and not the treasury of human inheritance would seem a name more fitting for the series as a whole. Dr. Bell has made a comprehensive and critical summary of observations on the peroneal type of progressive muscular atrophy with special emphasis on its ætiology and inheritance. From her data it appears that the tendency to transmit this congenitally installed defect is strong and equal in parents of either sex; 50 per cent. of children, one of whose parents is affected, can be expected to develop this disorder, although suppression of the disease is less rare than is that of some other diseases of the same genetic type. Sporadic cases provide a much smaller proportion of the whole than in glaucoma, glioma retinae or paralysis agitans, but larger than in Huntington's chorea. One interesting observation, not readily explicable, suggests that it may prove possible to predict which of the children who carry this inheritance will develop the actual manifestations of the disease, by testing their ability to taste phenyl-thiocarbamide; the inference is that the symptoms will appear only in those who are non-

tasters. It is curious that inheritance in this condition implies not merely liability to the disease, but liability to show the earliest symptoms at just the same age, to present the same typical or atypical distribution in exactly the same sequence, and to develop the same uncommon complications. The data concerning age and nature of onset, symptomatology, duration, complications, and pathology are all discussed. No unexpected observations seem to have emerged and the picture of the disease remains that which has hitherto been accepted.

### Lobar Pneumonia and Serum Therapy

By FREDERICK T. LORD, M.D., Clinical Professor of Medicine, Emeritus, Harvard Medical School; and RODERICK HEFFRON, M.D., Field Director, Pneumonia Study and Service, Massachusetts Department of Public Health. New York: The Commonwealth Fund; London: Humphrey Milford, Oxford University Press. 1936. Pp. 91. 4s. 6d.

THIS is the first of three projected publications arising out of the study of pneumonia, originated by Dr. G. H. Bigelow and financed by the Commonwealth Fund, in the State of Massachusetts. It deals with the general principles of serum therapy in lobar pneumonia. Methods of pneumococcus typing, the selection of suitable cases for specific treatment, dosage and administration of serum, the reactions which may occur, and the ultimate results and benefits of serum therapy are discussed fairly and clearly.

If the risks of serum reactions are stressed unduly, it is probably because the authors feel that in a

crusade for the wider use of a new therapeutic measure every care must be taken to avoid accidents which might bring it into disrepute. The mortality-rates for lobar pneumonia are higher in America than in this country and rather larger doses of serum are recommended than are used here, but the results from serum therapy in the two countries are quite comparable. Practitioners who are interested in this addition to our therapeutic armamentarium should read this monograph in conjunction with the report on the subject to the Therapeutic Trials Committee of the Medical Research Council (see THE LANCET, 1934, i., 290).

### Mechanics of Normal and Pathological Locomotion in Man

By ARTHUR STEINDLER, M.D., F.A.C.S., Professor of Orthopædic Surgery, State University of Iowa. London: Baillière, Tindall and Cox. 1935. Pp. 424. 36s.

THIS careful analysis of the mechanics of gait is based on a wide study of the literature and of researches all over the world, as well as on Prof. Steindler's own investigations on a vast mass of clinical material during his long professional career. The book has thirty chapters, of which the first four and the last are devoted to general mechanical principles; one chapter is devoted to the mechanics and pathology of bone, and five to the mechanics and pathology of muscle, including fatigue. Then the human machine is discussed in anatomical order, beginning with the trunk (spine, pelvis, thorax, abdomen) and travelling down the lower limb from the hip to the foot, and down the upper limb from the shoulder to the fingers, while the final chapters are devoted to a summary of the gait, both normal and pathological. A good bibliography is appended to the chapters. It is pleasing to find stress laid on a matter often overlooked by teachers and gymnasts: the amount of work involved in "standing at ease." This work is assessed as demanding 12 per cent. over the basal metabolic rate. The important part played by the abdominal muscles in maintaining the posture of the spine, and that of the intrinsic muscles of the hand in its activity is also emphasised. In an interesting discussion on deformities due to muscle-contractions the author points out that three groups of causes give diverse effects: (1) shrinkage from *fibrosis* of the muscle gives the greatest deformity, and is most noticeable when one stretches the damaged muscle; (2) *spastic* shortening is greatest when the muscle is at its least length; once the muscle has been pulled out, the spasm disappears (e.g. the tendo Achillis relaxes in full dorsiflexion); (3) shortening of a muscle, whose antagonist is paralysed, is never extreme. These are points of great importance when treatment is under discussion, but are frequently overlooked. There is also a valuable analysis of the different types of function of the human arm—e.g., as a flail in some sports, such as golf; as a fixed rod, straight for pushing, locked in flexion for some phases of boxing; and as a tensile spring for hanging from a trapeze.

The book is well illustrated and some good photos of the range of the human spine in different planes are reproduced; this range is actually much less than it appears to be in the living form, where limb movements supplement and appear to magnify the movements. Generous acknowledgment is given to the work of Goldthwait on the function of human posture, but the photos of good posture would not satisfy that pioneer. Prof. Steindler gives an interest-

ing study of phylogenetic changes on the centre of gravity, and of the anatomy and pathology of the spinal column. One is glad to find in the pages of such a master in the treatment of scoliosis a warning against the insidious and almost inevitable development of paralytic scoliosis and a statement that almost the only prophylaxis is to develop the reserve forces of the musculature, especially by respiratory exercises and care of the abdominal muscles.

This book should be studied in detail by every surgeon whose work is with bones and joints; while practitioners in every branch of medicine will find it worth while to consider thoughtfully the conclusions which the author brings forward at the end of each chapter. Intelligent appreciation of the physical and mathematical data on which Dr. Steindler bases this study may be a strain upon those whose first professional examination is a matter of ancient history, but most will be willing to trust the word of an expert and will not attempt to follow or confirm his calculations.

### Woman

By HERMANN HEINRICH PLOSS, MAX BARTELS, and PAUL BARTELS. English edition by ERIC JOHN DINGWALL. Vols. III. London: William Heinemann (Medical Books) Ltd. 1935. Pp. 2018. 8 guineas the set.

THESE three large volumes contain the first English translation of a work which has been well known in Germany and elsewhere for years and has passed through many editions. Originally conceived by Hermann Heinrich Ploss some fifty years back, the last issue appeared about nine or ten years ago, and it is a translation by Dr. Dingwall of this edition which has now appeared in English.

In these volumes, which are profusely illustrated, it is claimed that at least most of the activities of woman are shown, to some extent, as they appear throughout the world. In the first volume the female organism is considered in her anthropological, psychological, and æsthetic aspects, including the conscious cultivation of beauty and the attitude towards women found in folklore and traditional religion. After this comes the description of the female genitalia, external and internal, and then consideration of women's social life and status and spheres in the ancient and modern world, with the influences of religion on these matters. This is followed by a discussion of the girl before puberty, prenatal, during childhood, and reaching maturity; anthropological and ethnological considerations of menstruation go with this, including the study of "puberty rites" and popular superstition on the subject. It is evident, without giving lists of the subjects in the other volumes, that the work has been planned on broad lines.

In the second volume an interesting and important section is that which deals with prostitution and with brothels. This section seems to bear the editorial imprint, and leaves a more connected impression on the reader's mind than the greater part of the book, in which all kinds of observations appear to be thrown together in a somewhat haphazard way. It is of interest to learn that Joanna I. of Naples founded a brothel with intention to benefit her people, and established laws for its proper government, one of which provided for a weekly examination of its inmates by a surgeon, with segregation when necessary. The variations in the social status of women among different peoples is discussed at considerable length. This is only one of many matters in these

volumes which have interest apart from anthropology. For example, women suckle their children up to the age of 12 or 14 among the North American Indians and the Esquimaux, while in upper Bavaria, as Waldeyer pointed out 30 years ago, this female function is despised; Toldt related this attitude in many parts of the Tyrol to the wearing of stiff clothing which made suckling difficult. In many races confinement seems to be commonly without help, and usually easy. More difficult birth is probably commoner where there is racial mixture, especially when the father comes from a larger stock; definite expert information is wanting, however, on this matter. The post-partum uterus is "put into place" in various ways; the Tanganyika woman is stuffed with goat's flesh till she can swallow no more, combining an unusually full meal with downward pressure on the uterus. The duration of the puerperium varies remarkably, without any evident association with races or peoples. The suggestions that it varies with the period of lochial discharge, or with the falling off of the cord, are not convincing. Little seems to be known about the matter, which may be connected with ideas of "uncleanness." Scattered through the volumes is an enormous amount of data which gives the impression of having been accumulated rather than assimilated. An anthropologist or ethnologist who wants to know something about woman's ways in any place will find in this book whatever may be known on the matter; what value he may attribute to it and what use he may make of it is in his own hands. He will find here many statements made by one authority and flatly contradicted by another—but to that he is probably not unaccustomed. Perhaps the greatest fault of this work is the fundamental one that it has been written throughout from the standpoint of a man who tends to see woman's activity against his own background. Albrecht's dicta on the female skull, for example, are informed by the male sense only, and there are many other and more important aspects of women's functions, perceptions, ideas, and standards which are clearly not understood by the other sex. The differences of structure are dealt with adequately enough; a just appreciation of differences of outlook and their significance for the development of the human race is perhaps necessarily lacking.

### The Individual Criminal

*Studies in the Psychogenetics of Crime.* Vol. I. Cases 1-5. By BEN KARPMAN, M.D., Professor of Psychiatry, Howard University, Washington. Washington: Nervous and Mental Disease Publishing Co. 1935. Pp. 317. \$4.50.

ANY empirical attack upon the problem of criminal psychology is welcome. Prof. Karpman has aimed at producing such a study, as the outcome of years of work among prisoners. In an earlier volume he published detailed case-studies, for which he here supplies the interpretation. He is dissatisfied with the descriptive psychiatric approach to criminal behaviour, and, on the other hand, he finds that the psycho-analytic method has failed to contribute significantly to the solution of the problem because of fallacious assumptions as to the mechanisms at work. He takes each of his five cases in turn, formulates the situation and the psychogenesis, and reviews the diagnostic aspects. Appended to three of the records are the professional comments of Mr. William Brandon, himself a patient in the Criminal Department of St. Elizabeth's Hospital: they are obviously based on

first-hand knowledge of the underworld and add to the value of the book. The psychiatric explanations which Dr. Karpman offers are debatable, but are carefully reasoned and based on an adequate psychiatric experience. His unbiased approach to the problem of therapy is plain in the essay with which the book ends: here he points out the difficulties which imprisonment puts in the way of effective individual treatment. These obstacles have apparently been more stubborn than English experience might lead one to expect: the difference probably depends to a considerable extent on the inveteracy of the criminal behaviour under consideration. It would be unsafe to generalise from Dr. Karpman's misgivings, though his main standpoint about punitive measures is no doubt valid. This well-documented and reasoned study of a few cases is a useful complement to the larger statistical surveys which are valuable in criminology.

### Essentials of Psychopathology

By GEORGE W. HENRY, M.D., Associate Professor of Psychiatry, Cornell University Medical School, N.Y. London: Baillière, Tindall and Cox. 1935. Pp. 312. 18s.

Dr. Henry seems to have aimed less at presenting psychopathology as a whole than at introducing the reader to some of its important problems, explaining to him what are the dynamic formulations of human psychology now in use, and telling him how to collect and evaluate the facts of a psychiatric case. The book is elementary and clear, though difficulties are not glossed over. There is much illustrative clinical material, which will no doubt be useful to those who have no psychiatric experience of their own to draw upon. Through these clinical records and the account of his own researches in psychiatry, the author's personal interests are made manifest to the reader and stimulate his interest. The first third of the book deals with such physiological and biological matters as heredity, constitution, cerebral function, and the vegetative and toxic factors in mental illness; the last third is concerned in detail with clinical methods of examination and description; and in the middle of the book—which should be the meat of the sandwich—comes the psychopathology proper. It is not however a meat sandwich, but one which contains paste of rather indefinite flavour—a vague account of the integration of personality, mental dynamics, and the maladjustments of childhood.

### Marriage in My Time

By MARIE C. STOPES, D.Sc., Ph.D. London: Rich and Cowan Ltd. 1935. Pp. 247. 6s.

THIS volume appears in a series which deals with contemporary institutions and activities which are in a state of transition. The author sees in marriage to-day "a flux of conflicting needs, customs and mores and from that flux the conscious evolution of something nobler and higher than humanity has yet experienced." According to Mrs. Stopes the Victorian outlook on marriage was influenced by the Pauline and Augustinian morality, which was primarily based on a false cosmogony arising from the belief that, in view of the imminence of the second coming and the end of the world, marriage was likely to be a hindrance rather than a help to Christians. The book is written with the author's well-known vigour and clarity of style. It contains little that will be of direct utility to medical readers, but most people will find the arguments interesting.

especially in the two chapters which deal with the author's activities in connexion with what she calls the marriage tax and the woman's right to retain her maiden name.

### Clinical Miscellany

Vol. II. By F. F. HARRISON, C. C. MCCOY, M. A. McIVER, G. M. MACKENZIE, M. F. MURRAY, R. M. PIKE, J. H. POWERS, D. K. SCHEIDELL, and R. C. TANZER. The Mary Imogene Bassett Hospital, Cooperstown, New York. Springfield, Illinois, and Baltimore, Maryland: Charles C. Thomas; London: Baillière, Tindall and Cox. 1935. Pp. 218. 13s. 6d.

THIS miscellany gives an account of certain more or less rare clinical conditions correlating as completely as possible the clinical and laboratory findings in each case. There are nine contributors. Dr. John H. Powers, in collaboration with Dr. Dorothy K. Scheidell, writes on cholecystitis in childhood and, with Dr. F. F. Harrison, on primary carcinoma of the Fallopian tube. He also writes on decubitus ulcers and idiopathic urethral stricture. Dr. Harrison contributes a paper on post-vaccinal polyneuritis, and another, with Dr. M. F. Murray, on anterior poliomyelitis. Other subjects dealt with by Dr. Murray are juvenile acrodynia, fatal hæmorrhage from an eroded vessel in scarlet fever, and apparent cure of mediastinal Hodgkin's disease. He also reports, with Dr. Monroe A. McIver, three cases of congenital anomaly of the intestine. Dr. McIver also writes on intussusception and carcinoma of the vulva, Dr. C. C. McCoy on undulant fever complicated by hepatic cirrhosis, and on *Staphylococcus aureus* bacteriæmia possibly associated with undulant fever. Dr. R. C. Tanzer reports cases of bacteriæmia arising from hand infection, and Dr. G. M. Mackenzie writes on various rare blood conditions. In the chapter on blood cultures he has collaborated with Dr. R. M. Pike. The cases are thoroughly and carefully worked out and followed up. A bibliography is appended to each chapter and an index to the book.

### Incompatibilities in Prescriptions

Sixth edition. By EDSSEL A. RUDDIMAN, Ph.M., M.D., Research Chemist with the Ford Motor Co., Dearborn, Mich.; and ADLEY B. NICHOLS, Ph.D., B.Sc., Assistant Professor in Operative Pharmacy, Philadelphia College of Pharmacy and Science. New York: John Wiley and Sons Inc.; London: Chapman and Hall Ltd. 1936. Pp. 337. 13s. 6d.

THE primary object of this book is to provide a compact source of information for pharmacists and to present to the physician data pertinent to the success of the prescriptions he writes. It is divided into two parts. Part I. considers the substances in alphabetical order and every conceivable incompatibility appears to be formulated. From the prescriber's point of view the book would be much improved if stress were laid on those incompatibilities which are likely to occur in actual practice. Interesting information is given on the decomposition of aspirin in mixtures containing potassium citrate, a combination which occurs in mist. acid. acetylsal. of the National Formulary. Hydrolysis to an extent of 10 per cent. occurs in one day, 50 per cent. in a week, and practically all the aspirin is decomposed within three weeks. The inclusion of acriflavine, anæsthesin, calcium gluconate, ephedrine, thiosinamine, and thyroxin shows that the revision has brought the book well up to date. The decomposition of soluble phenobarbitone in aqueous solution is considered,

and the influence of temperature on the rate of decomposition is noted.

Part II. consists of typical examples of prescriptions containing incompatibles. Some of these are much too complicated to afford much help to the prescriber. A number of the substances included, although widely prescribed in America, are rarely encountered in this country. The table of solubilities and the index of incompatibilities and prescriptions enhance the value of the book. On the whole the book has much to recommend it, being one of the most comprehensive treatises on the subject of incompatibilities but it will be more useful to the pharmaceutical student than to anyone else.

### The 1935 Year Book of Surgery

*General Surgery.* Edited by EVARIS A. GRAHAM, A.B., M.D., Professor of Surgery, Washington University School of Medicine; Surgeon-in-Chief of the Barnes Hospital and of the Children's Hospital, St. Louis. Chicago: The Year Book Publishers; London: H. K. Lewis and Co., Ltd. 1936. Pp. 838. 12s. 6d.

THIS useful review of surgery during the past year maintains the high standard set by its predecessors. The matter has been well selected and well arranged, and nothing of importance that has occurred has been omitted. These year books are almost indispensable to any actively practising surgeon, even to those who think they have kept well abreast of current literature. Those who examine one of them, notably this one, will almost certainly find papers which have escaped their vigilance. Even if their reading has indeed been exhaustive as far as the year's advances are concerned, they will still be glad to have a convenient summary of original work which they have previously noticed, or to be reminded of communications which they have forgotten.

### Life and Works of Charles Barrett Lockwood

By ERIC C. O. JEWESBURY, M.A., B.M. Oxon. London: H. K. Lewis and Co., Ltd. 1936. Pp. 103. 3s. 6d.

THE major part of Dr. Jewesbury's book was published during the past year in the *St. Bartholomew's Hospital Journal* and many may have read there the biographical notes on an exceptional man. In the medical school of St. Bartholomew's Hospital Lockwood commanded notice from many points of view. One heard him described now as anatomist, now as a pioneer of aseptic surgery, and now as an adventurous sailer of small boats; as a coiner of epigrams, and a wonderful teacher he claimed attention. Dr. Jewesbury points shrewdly to the qualities which lay behind this varied display—qualities which themselves never varied. Lockwood was always inquisitive for knowledge, untiring in the search for it, rigidly accurate, and quite adventurous; yet he was a simple man. Absorbed in his work, no man here was ever more zealous for perfection; but he equally rejoiced in play, as any will recognise who read the journal entitled "Swin, Swale, and Swatchway" kept by himself and his intimate friend Lewis Jones, as a record of experiences round the mouth of the Thames in a little sailing boat. Lockwood has been dead more than 20 years, but those who knew him are bound to remember him, and those who did not know him should learn something of him. Dr. Jewesbury has done well to republish his chapters in the *St. Bartholomew's Hospital Journal*, which form the Wix prize essay.

### Researches Published from the Wards and Laboratories of the London Hospital during 1935

London: H. K. Lewis and Co., Ltd. 7s. 6d.

THIS collection of 28 publications from the London Hospital covers an unusually wide range in subject-matter. S. P. Bedson has demonstrated the value of the complement-fixation test in the clinical diagnosis of psittacosis, while J. O. W. Bland has succeeded in obtaining, with the late R. G. Canti, a cinematographic record of the life cycle of this virus—thus confirming his earlier work with Bedson in which the existence of this cycle was first described. Some further observations upon anti-cancer sera are made by T. Lumsden and his co-workers. The unreliability of the Schubert-Dannmeyer test for cancer is demonstrated by E. R. Holiday and F. Campbell Smith. The two contributions to hæmatology in this volume are of a fundamental character: in the first E. R. Holiday, Phyllis Tookey Kerridge, and F. Campbell Smith criticise the hæmoglobinometers in common use and report the results of their investigation of the photo-electric hæmoglobinometer favoured in the Hale Clinical Laboratory; in the second C. Price-Jones, Janet Vaughan, and Helen Goddard have established and confirmed a number of hæmatological standards for health. A. C. Crooke and Dorothy Russell have shown, by differential cell counts, a marked decrease in the numerical proportions of basophil cells in the anterior lobe of the pituitary in a series of cases of Addison's disease. In another paper, which was the subject of a leading article in THE LANCET, A. C. Crooke describes a peculiar hyaline change in the basophil cells in cases exhibiting the syndrome known as "pituitary basophilism." Dorothy Russell and C. Donald have directed attention to a malformation of the hind brain in a series of cases of spina bifida and have shown how this may be the mechanical cause of internal hydrocephalus. M. A. Abbasy, L. J. Harris, S. N. Ray, and J. R. Marrack have investigated the response in adults and children to measured doses of vitamin C and have shown how urinary analysis indicates the level of intake over long periods. R. S. Aitken and C. Wilson have been unable to confirm Bohn's claim that a pressor substance can be demonstrated in the ultra-filtrates from the plasma of patients suffering from Volhard's "pale" hypertension.

On the clinical side a comprehensive review by R. A. Brews of 72 cases of hydatidiform mole and 16 cases of chorion-epithelioma leads to the conclusion that conservative treatment is rewarded by a very low rate of mortality. The value of the Aschheim-Zondek and Friedman tests is discussed. Clinical studies of actinomycosis in childhood by R. W. B. Ellis, of occupational argyria by J. M. Harker and D. Hunter, and of dyschondroplasia and other bone diseases by D. Hunter are noteworthy contributions.

## LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY

### ANNUAL GENERAL MEETING

THE annual general meeting of the society was held at Victory House, Leicester-square, W.C., on May 6th.

Sir CUTHBERT WALLACE, the president, in putting the resolution for the adoption of the annual report, said that he had presided before as the merest tyro, deputising for Sir John Rose Bradford, when he knew little about the work, but that during the last twelve months he had attended committees fairly often, and from the experience gained he had come to feel that professional life is very precarious. "A man does as well as he can," he said, "and acts the

best he knows how, and yet he gets into trouble somehow or other. It has been a revelation to me what pitfalls there are in general practice and indeed in every kind of practice. I can give the society a warm testimonial as to the tremendous amount of work it does and the collective wisdom of its council and committees. Sitting at their meetings my head has sometimes buzzed with the detail, but it seemed to produce no like effect on the heads of more accustomed members." The professional man must, he said, safeguard himself and join a society like this directly after qualification, instead of waiting as so many do for the trouble to materialise, and he was glad to know that many public bodies are insisting upon the medical members of their staff joining one of the societies in order to protect themselves.

Commenting upon the successful work of the society, he said "We have 898 new members, and the total number on our books at the end of the year was 14,455. Judging by the number of applications for advice and assistance we have had during the year (1401), 10 per cent. of our members have got into trouble of some sort. If we take the same proportion of those present at this meeting it means that four or five of us will encounter trouble before this year is out. That is an argument often heard in cancer campaigns—one in seven of those present will get cancer. Here it is one in ten who will have occasion to seek the assistance of the society.

"Another thing which interests me as a surgeon is the eternal question of swabs left in after operation. It does not appear to matter what precautions are taken, whether the surgeon counts them himself, has nurses to count them, or trusts to luck, the time will come when there will be a suspicion that a swab has been left in. On two occasions it happened that nurses reported to me that there was a swab missing, but in both cases the swab was found with very little difficulty."

Sir Cuthbert Wallace urged the necessity of the members in difficulty consulting the society at the outset, delay or attempts to help themselves were often unfortunate. He moved the reception and adoption of the annual report, statement of accounts, and balance sheet, and the resolution was carried unanimously.

On the motion of Dr. W. J. O'DONOVAN, seconded by Mr. G. F. STEBBING, Sir Cuthbert Wallace was unanimously re-elected president. The re-election of the existing vice-presidents and officers followed, when Dr. P. B. SPURGIN said that the hardest worked officer of the society was the secretary, Dr. Fegen, in saying which he was not disparaging others. They had, he said, a secretary who for many years had devoted great interest and skill to this work. He heartily proposed Dr. Fegen's re-election.—Dr. HUGH WOODS, in seconding, said that there could be no better proof of Dr. Fegen's good work than the way the society had continued to progress steadily and regularly, and the resolution was carried unanimously.

Dr. ROBERT HUTCHISON proposed a vote of thanks to the solicitors, Messrs. Le Brasseur and Oakley, who were, in legal matters, the brains of the society. For the special knowledge which they brought to bear upon the society's affairs he held that they deserved hearty thanks.—Dr. STEBBING, in seconding the resolution, expressed his admiration of this legal work and the resolution was carried by acclamation.

A vote of thanks was accorded to the president for his conduct of the chair.

## THE SCOPE OF NATURAL SELECTION

DARWIN'S main thesis in the "Origin of Species" was that the great majority of live organisms born into the world failed to reach maturity, that the progeny of an animal or plant vary spontaneously among themselves, that those which are better fitted to meet the changes and chances of life would be more likely to reproduce themselves, and that these favourable variations, if heritable, would be perpetuated and those which were unfavourable would be eliminated. His clear statement of these necessary consequences of the facts won immediate consent, and the world in general agreed, and still agrees, that they had here a tolerably rational explanation of the adaptation of live things to their surroundings. But his further suggestion that this process of "accidental" variation and consequent selection would account not only for the separation and segregation of the very obvious units known as species but for the whole of the evolutionary process was from the first looked upon with some suspicion, and biologists became more and more uneasy not about the fact of natural selection but about the variations which are its raw material and about its consequences. Thus the symposium on the subject opened last week at the Royal Society by Prof. D. M. S. WATSON led to an interesting survey of current opinion.

In thinking of spontaneous variation DARWIN had in mind mostly the small, even tiny, differences which can be seen in any brood, and he thought that these might be progressively accentuated by repeated selection to almost any degree; he knew of the occurrence of the much larger and more dramatic changes, in his day called "sports," but deliberately excluded them from his argument though he thought later on that he might have done well to give them more consideration. The experimental evidence obtained since is against his idea that small fluctuations can give such large effects as he required, though it is of course still possible that a different answer would emerge sub specie æternitatis. And there seems now to be general agreement (Prof. E. W. MACBRIDE strongly dissenting) that the sudden changes described by DE VRIES as mutations of which the precise mode of inheritance was revealed by MENDEL are the only variations which can be considered effective in evolution. Some mutations involve large changes in structure and appearance, and it was through these that their occurrence was first discovered, but there is no reason to doubt that similar capers among the chromosomes may give rise to morphological changes of any degree, and also to variations which are perceptible only by examining function. Prof. N. TIMOFEEFF-

RESSORSKY had found that small physiological mutations demonstrable by measuring viability under conditions of overcrowding were quite common in wild populations of *Drosophila*, much more common in fact than those involving gross changes in structure, which meets the difficulty made at one time that mutations were too infrequent to be of much evolutionary significance. Most mutations are not adaptive, and as Prof. R. R. GATES emphasised, have a lethal rather than a survival tendency and, acting on such material, natural selection really acts, as Prof. J. B. S. HALDANE pointed out, in keeping a species constant and preventing wild animals and plants running riot as protected dogs and cabbages do. But the occasional favourable mutation will in the same way be favoured, though considering the intimate adaptation of organism to environment such must presumably be quite uncommon.

Other points of importance were brought forward mostly by the botanists. DARWIN looked for characters of survival value chiefly in adult animals and plants, and some of his followers went to rather extravagant lengths in finding meanings and virtues in all the odds and ends of manifest structure. They did not realise that most selection takes place in the early stages, in the young seedlings of plants as Prof. E. J. SALISBURY'S observations showed—that is long before the characteristic features of the adult have appeared. The intensity of this infantile mortality must vary so largely with the number of young produced that its significance is perhaps different in different instances. In a uniform environment animals and plants maintain their numbers roughly constant from year to year, and selection in the foxglove where one individual produces half a million seeds must be quantitatively and perhaps qualitatively different from selection in bats where two yield one young one per annum. When and how the elimination of superfluous young takes place is a matter on which much more information is needed; that elimination is selective follows a priori from its occurrence, but of what quality is being selected we are almost entirely ignorant. These are points which are fundamental to the Darwinian argument, and it is singular that so few attempts have been made to discover what *does* happen compared with the immense amount of work which has been put into the investigation of the possibilities. Prof. SALISBURY also laid stress on the overwhelming influence of competition in plant communities, and Dr. W. B. TURRILL pointed out that a change of environment might produce as large an alteration in a plant as a change of gene.

Of the reality of natural selection in eliminating the individuals which try to transgress the bounds of their adaptability (as Mr. C. DIVER put it) no one expressed any doubt, and those who, like Prof. WATSON, were dubious about its selective effect seemed to overlook the plain fact that if a harmful agent kills half a population the dead must be those which are more susceptible to the agent and the survivors those which are more resistant. The agent ceases to be selective only

if it kills all or none. Of the relation of natural selection to evolution there was much less certainty. Unfortunately none of the speakers represented the orthogenetic view, advocated particularly by the mammalian palaeontologists, that evolution is a pre-ordained development with a purposive end. And no one but Prof. MACBRIDE put in a word for LAMARCK and the inheritance of acquired habits, the evidence for which is now definite and considerable. Perhaps the truth is that evolution has been achieved in a variety of ways or by combinations of different modes. Mutations, for instance, have appeared up to the present to occur at random or at the most by some system inherent in the organism concerned. It would be distinctly helpful if they could be shown to have some relation to the environment as is suggested by the observation that the typhoid bacillus will ferment lactose if it lives in its presence long enough. A learned bacteriologist might indeed have been included with advantage in the panel at the meeting.

### OPERATION FOR CANCER OF THE STOMACH

CANCER of the stomach is one of the most insidious and most fatal forms of cancer. In the past the outlook has been so serious that by some physicians surgery has been held to be inadvisable. Of 149 consecutive cases of carcinoma of the stomach admitted to St. Thomas's Hospital during the 13 years 1920-32, Sir CUTHBERT WALLACE, or a member of his firm, regarded<sup>1</sup> 122 as unfit for excision (their average survival was 3.3 months); of the 27 in whom gastrectomy was performed the average survival was 12.3 months, but 4 lived more than three years and 1 more than six. Their results were displayed in an admirably graphic way which deserves imitation. Bad though the outlook is, there is now, as Sir JAMES WALTON pointed out in an oration before the Medical Society of London which we published last week, no reason to speak of it as hopeless. He has operated upon 461 patients with carcinoma of the stomach and has made a number of original observations. Of the rarer forms, that growing at the greater curvature presents points of interest. Inasmuch as at first it causes no alteration in digestion and does not lead to obstruction at the pylorus, it is commonly of large size when first seen by a surgeon, sometimes immense. Yet this large fungating, frequently necrotic mass may be removed with good result, for the metastases are usually limited to the glands of the greater curvature. In cancer of the stomach operation should never be decided against because of the size of a palpable tumour. WALTON's figures for the incidence of carcinoma in chronic gastric ulcers agree with those of W. D. NEWCOMB, that is 10 per cent. of cancers originate in a gastric ulcer; eight of his cases apparently arose in the scar of a gastric ulcer after gastro-jejunostomy had been performed. The St. Thomas's surgeons regarded the shortness of history of gastric symptoms in almost all their

cases as a strong argument against carcinoma commonly starting in a chronic ulcer.

The silent nature of the disease makes its early recognition difficult or impossible. WALTON found only 36 per cent. of his cases had been diagnosed sufficiently early to allow a radical operation—and this in spite of improved radiography. He added that he could not but feel that the figures for operability could be improved. But how? His answer is by operating upon all patients developing dyspepsia after middle age unless a growth can be definitely eliminated by X ray examination and test-meals. But even this plan would not gather in, at an early stage, those patients in whom a cancer has been growing for some time, either with no symptoms at all or with symptoms so vague that they pass almost unnoticed. When the diagnosis has been established, WALTON's practice is only to refuse operation if there is definitely evidence of secondary deposits. He finds it possible to remove an increasing number of growths; and this is a hopeful sign although as the range of operability is increased the primary mortality does not tend to shrink. It is 28 per cent. Nor are the late results of resection good. Of 324 patients who were operated upon more than five years ago, only 20 are still alive, although single patients have survived for 19, 17, 15, 14, 10, and 7 years. One of his observations is of fundamental importance from the surgical point of view. The experience of these 461 cases has shown that no reliable deductions as to the future course of the case can be drawn from the appearance of the growth or of its disposition or situation. Small tumours apparently favourably situated for radical removal may, after resection, be followed by the rapid formation of metastases and lead to early death, whereas large masses removable only with difficulty and some hazard may be followed by years of health. This same fact is brought out by Prof. W. ANSCHÜTZ of Kiel in a communication published on p. 1175 of our present issue. The phenomenon is by no means peculiar to cancer in the stomach; it is characteristic of cancer in almost any part of the body. The outlook after operation depends more upon the defence of the organism to malignant growth than upon any other factor. This is the experience of all who have had much experience in cancer work. For early diagnosis ANSCHÜTZ lays great weight upon the X ray findings and the presence of blood in the fæces; a normal radiogram and the absence of occult blood, he says, make the presence of a carcinoma improbable in the highest degree. At the University surgical clinic in Kiel the normal operation for carcinoma of the stomach is resection, which is done even in the presence of irremovable glands or other metastases. The results from gastro-jejunostomy have been so disappointing that this procedure has been almost given up. Resection is done at the earliest possible stage and even in old people. The primary mortality is as high as that reported by WALTON, but the results are striking, and sometimes unexpected, as the graph illustrating the article shows.

## INDUCTION OF PREMATURE LABOUR

OF the three great divisions of clinical practice, gynaecology is the last to be chastened into the humility which breeds conservatism. First in medicine, towards the end of last century, and then in surgery, pride in ability to modify processes of disease and repair, or to hasten resolution, has given place to a critical attitude towards active treatment. The tendency is to require more than an impression of the efficacy of any drastic form of intervention. The demand is now for evidence (1) that patients treated otherwise or not treated at all do less well, and (2) that the harm, immediate or remote, which may result from activity is less to be feared than the outcome of expectant treatment. This more scientific attitude has led not to the abandonment of procedures favoured in the past but to restriction in their application: blood-letting is still the practice in selected cases, for example, and large portions of a colon, when clearly diseased, are removed with benefit to the patient. The discussion at the British Congress of Obstetrics and Gynaecology held last month<sup>1</sup> showed that except in malignant disease hysterectomy and oöphorectomy are now falling into disfavour, and that increasing importance is being attached to the conservation of even small portions of gland tissue. Obstetrics is also coming into line, in so far as the popularity of Cæsarean section is waning. But there is one form of intervention which has been more common of recent times in Great Britain than in other countries, following the attention paid to antenatal supervision. A chief aim of such supervision has been the detection well in advance of conditions likely to lead to difficult labour, and in many patients referred from the clinic to the family doctor or to a hospital at the thirty-sixth week with a tentative diagnosis of disproportion, premature labour has been induced for fear of obstructed delivery.

The detection of disproportion, and the management of cases in which it was supposed to be present, have long been regarded by the profession and public as one of the triumphs of antenatal work. It will come as a shock to many people therefore to learn that the benefits of this apparently sound principle should even be regarded as doubtful, let alone condemned. It is particularly noteworthy that at the debate reported on p. 1178 of this issue the motion that the surgical induction of premature labour should play no part in the treatment of pelvic contraction or disproportion in primigravidaë was proposed and supported by three of the younger men in obstetrics, and that a large section of those present voted with them. It will be recalled that Mr. J. H. PEEL recently published in our columns<sup>2</sup> an account of a hundred consecutive cases in which induction had been performed for disproportion in primigravidaë. These results were bad; there was a high maternal morbidity and a fetal mortality of over twenty, and Mr. PEEL emphasised, what few have realised

hitherto, the high incidence of uterine inertia that follows surgical induction, bringing other dangers in its train. Those who supported the motion last Friday argued on similar lines, and some depressing figures from the practices of the speakers or from hospital statistics were quoted. Even those whose faith in figures is small will have been impressed by the disturbing facts recorded. A point of particular interest emerged in the wide variation in the percentage of labours induced for disproportion at the different schools throughout the country. In one centre the inductions for this cause reached 15 per cent., in contrast to the practice, say, at Willesden and Croydon where among some thousands of cases not one premature labour was induced for disproportion. The medical officers in charge of the centres at these two places were able to show very satisfactory figures as regards maternal morbidity and foetal mortality, and also, what is of the utmost importance, extremely low figures for Cæsarean section. It might be argued that the incidence of contracted pelvis varies in different parts of the country; it seems to be common in Glasgow and Lancashire and rare in London. But Mr. ARNOLD WALKER pointed out that during the last few years the patients under his care at Willesden were drawn from all the depressed areas of the British Isles, and he therefore regards them as representative of the population as a whole.

Those who defend the premature termination of pregnancy fear that failure to induce will lead to an increase in foetal mortality and in Cæsarean section and craniotomy; but the figures supplied by several speakers should allay these fears. Indeed it was shown that the number of Cæsarean sections in any particular institution seems to vary directly with the number of inductions: the apparent paradox may be resolved by considering the proverbial danger of looking for trouble. An argument put forward on behalf of the radical policy—induction when in doubt—is that to "wait and see" leads to great difficulties in general practice. On the other side it might be said that the latter course would relieve the general practitioner of the responsibility of making the difficult decision whether to induce. By waiting until near the expected date he will find that most cases of apparent disproportion make normal progress as the foetus increases in size. In other words, the alarming non-engagement of the foetal head has not been due to a real misfit. Where this does not happen, that is, when in the last weeks of pregnancy there is still doubt whether a living child will pass through the canal, the case should be handed over to an experienced obstetrician.

Whether the obstetric pendulum has now swung too far in the conservative direction must remain in doubt for a few years. It is, however, certain that if "meddlesome midwifery" has been banned with some success from the labour ward, it has of recent years reappeared in antenatal supervision. In the course of time principles will be applied more correctly and the undoubted value of such supervision will be greatly enhanced.

## ANNOTATIONS

## SURGICAL RESEARCH

THE welcome gift of £25,000 from the Bernhard Baron trustees will make it possible for the Royal College of Surgeons of England to build and equip new laboratories. This will bring to fruition a plan for the development of surgical research which has long been taking shape in the minds of the College councillors. Some five years ago the upper floors of the College in Lincoln's Inn-fields were fitted up for surgical and pathological investigations and a little later Sir Buckston Browne endowed the research farm at Downe with a residential hostel attached. But neither in Lincoln's Inn-fields nor at Downe has it yet been possible to follow the example set by John Hunter at his Earl's Court seat. In dedicating the farm at Downe to the ideals of John Hunter, the then president of the College remarked "In the association of the surgeon with the biologist we look for the advances of surgery in the future," and the Bernhard Baron laboratories will provide research facilities for men on the staffs of London hospitals who wish to undertake investigations into problems suggested to them by their experience in hospital practice. Nor does their value end here. The College is already attracting to its laboratories men from all parts of Great Britain, from the British Commonwealth overseas, and from foreign lands, and they will now find a worthy centre for their varied activities. The College has in trust for the nation the world-famous Hunterian museum with its priceless collection of anatomical and pathological specimens. It is also the custodian of the Imperial War Collection formed during the war years and housed in the museum. The existing activities of the College in research are not confined to the field of surgery alone; it takes its share, for example, in the administration of the Imperial Cancer Research Fund. If surgical technique, as has been said, can develop little further, those who work at this London centre of investigation may find paths of future progress in biological surgery.

## BOARDING-OUT THE MENTALLY DEFECTIVE

IN public health circles increasing attention is being given to the socialisation or resocialisation of those who are unable, or likely from whatever cause to become unable, to take their proper place in the life and work of the community. Industrial and reformatory schools, rescue and preventive homes all have this object in view—there are, by the way, no preventive homes for boys. A special problem is presented by those who have suffered from mental breakdown and will require to lead a sheltered life in the future, or are the subjects of mental deficiency. A proportion of these can undoubtedly re-enter community life under suitable conditions of kindly care and supervision, when their happiness and self-respect will be increased by the knowledge that they are not shut off from the general life of their fellow beings, and that they can again be of some use in the house or on the farm. A few mental hospitals are boarding-out suitable patients in their own districts, either with relations or foster parents; recall to the hospital is at times necessary, but the results on the whole are satisfactory to the patients. They are also satisfactory in helping to break down the still widespread fear of persons who have been "under care"; further they are satisfactory from the ratepayer's point of view, for these patients cost

less and their absence helps to stave off a costly increase of accommodation at the hospital. Community care has long been in much more general use north of the Tweed than south of it; evidence of this may be found in the recent report of the Scottish Board of Control. Nearly one-third of the Scottish patients certified under the Mental Deficiency Acts are living in private dwellings, the proportion in England being a little over one in eight. In both countries a contributory cause of the boarding-out is no doubt the shortage of institutional accommodation, but in Scotland the importance is better recognised of using institutions as training places (the younger the patients are when they enter, the better) from which, when their period of training is over, they can be returned to community care if at all suitable. This resocialisation is one of the more hopeful signs for the future of mental deficiency practice.

## THE PREJUDICE AGAINST FINGER-PRINTING

WHY are we all so sensitive about the recording of our finger-print impressions? Even well-informed people, says the Commissioner of Police of the Metropolis in his latest annual report (Cmd. 5165, 1s. 3d.), are liable to misunderstand the matter. The wholly innocuous process of taking finger-prints is regarded as degrading, though it is as likely to assist in establishing innocence as in proving guilt. Few people, he remarks, object to the "identification parade" where a person is placed in a line with others in order to see whether complainants can identify somebody who is said to have committed robbery or assault. Nobody greatly minds if a suspect's arm is examined to see if he can be identified by the presence of tattoo markings. Yet the taking of finger-prints at any stage of the investigations is represented as the crowning insult to a possibly innocent man. In America there is a movement to extend the system of recording finger impressions to volunteers, in the hope that the collection will presently include the greater part of the population. No more doubts about persons who have lost their memories, no more failures to identify drowned bodies, no more mixing up of babies in hospitals.

The Commissioner notes the present difficulty in England with juvenile offenders. He denies that the recording of their finger-prints will reduce their chance of making a fresh start towards good citizenship. Without such records it is not always possible to give a magistrate the details of a lad's past history. One boy of 15, while several times in custody in London and at Hove, refused to have his finger-prints taken, as, under the present regulations, he is entitled to do. The magistrates never knew what kind of young man they were dealing with. On his last arrest in London he agreed to the impressions being recorded. The police at once were able to connect him with eight other house-breakings where he had left finger-prints; on learning this, he confessed to a further 16. It is easy to imagine the suspicion which must have fallen upon innocent persons before this identification could be established. Elsewhere in the Commissioner's report we learn the scope of the services rendered in the finger-print branch at Scotland Yard. During 1935 there were 21,767 identifications from 55,899 sets of finger-prints forwarded for search; 989 of the latter came from colonial and foreign police, and 5914 from Scotland and Ireland. The

collection now contains 563,411 slips. The regulations enabled 20,534 sets of prints to be received from prisons in England; in 13,714 cases the prisoner was found to have been previously convicted. It is doubtless the ends of criminal justice that the Commissioner has chiefly in mind when he asks us not to be so sensitive about our finger-prints.

Sir Francis Galton once wrote that there was "no prejudice to be overcome in procuring these most trustworthy sign-manuals." He was thinking perhaps of the experience of India where the inked fingertip enabled illiterates to make their mark for civil purposes and where the significance of the imprint, partly superstitious and partly ceremonial, has been comparable to the English practice of touching a seal or wafer and declaring that a document is thereby executed "as my act and deed." And yet our prejudices remain. We do not object to the registration of births, marriages, and deaths; we rely upon the evidence of these facts for purposes of identity. But, when we are invited to apply the simple method developed by Herschel and Galton, Faulds and Henry, and to furnish the means of universal identification through records which might be stored and classified by the Registrar-General at Somerset House rather than by the Commissioner of Police at Scotland Yard, we recoil from the suggested degradation.

#### EFFICIENT TREATMENT OF V.D. IN SEAMEN

VENEREAL diseases have always been rife among those whose calling means constant travel; and to treat such patients adequately is always difficult and sometimes impossible. From the public health standpoint the problem is of great importance in relation to men whose life at sea is interrupted by short calls at many ports. An international agreement signed at Brussels in 1924 provided for the free treatment of merchant seamen and watermen, without distinction of nationality, at the principal sea or river ports of the contracting countries. There are now 56 countries working this arrangement, and a revised list<sup>1</sup> of treatment centres in ports at home and abroad at which seamen can obtain treatment has just been issued by the Ministry of Health. Difficulties in the application of the agreement have been referred to the permanent committee of the Office International d'Hygiène Publique, and some important recommendations are contained in two communications from that office summarised in circular 1536 of the Ministry of Health. The "second communication" deals with the difficulties experienced by seamen in finding treatment centres open to them, as well as in ascertaining the days and hours of attendance. It is recommended that treatment should, as far as possible, be available at some time in the afternoons or evenings. Attention is drawn to the section of the agreement which requires that details of the facilities available shall be made known to the crews by masters of ships and ship-owners and by the sanitary officer at each port. Further recommendations are designed to ensure greater publicity through consuls in the ports and through the superintendents of seamen's homes and similar places. The "third communication" aims at securing more regular and uniform treatment for seamen in the earlier stages of syphilis. In the past difficulties have arisen from the fact that patients who attended many centres were treated according to many different schemes, with different drugs of varying dosage.

Under such circumstances regularity of treatment and adequate total dosage were rarely obtained. Now the excellent policy is to follow the principles of treatment laid down last year by the experts of the health organisation of the League of Nations.<sup>2</sup> Methods of adapting these schemes to the needs of seamen are discussed, and it is suggested that either the plan of intermittent treatment (I.) or the alternative continuous course (II.) be adopted. Attention is drawn to the importance of entering I. or II. clearly on the patient's personal card to indicate which course has been chosen, along with the stage reached in numbered weeks, and details of treatment and instructions given. Methods of obtaining regularity of treatment by bridging over the interval at sea are suggested and include schemes for coöperation with ships' surgeons or, in the absence of medical care, the substitution of oral remedies for drugs given by injection. The object of this standardisation is not to destroy the initiative of responsible medical officers, but to indicate satisfactory and uniform lines of treatment which may be modified at individual discretion. The recommendations should prove of great value to the medical officers of treatment centres and if carried out should bring a welcome improvement in the care of seamen.

#### AUTOMATIC VOLUME CONTROL FOR HEARING AIDS

DURING the last few years the technical construction of electric hearing aids has been greatly improved and they have become more widely used, to the advantage both of deaf persons and their friends. But they have a drawback which makes some people dislike using them and others to give them up entirely; a sudden loud sound is amplified to a degree which is unpleasant and may be even painful. For instance, in a theatre, when the volume control has been used to bring the amplification up to the level at which the performance on the stage can be clearly heard, a loud cough from a neighbour produces a disagreeable shock. The solution of the problem is an automatic volume control, which must come into operation almost instantaneously on very strong signals so as to avoid shocks of even short duration, and it must limit the loudness of sounds to a definite maximum which should be capable of variation to suit the sensitivity of various individuals; for many deaf people, especially nerve-deaf cases, are extremely sensitive to loud sounds. This control differs both in aims and in principle from the automatic volume control commonly employed in wireless receivers, where the strength of the carrier wave is used to vary the high-frequency amplification, so that strong and weak stations are received at approximately the same strength, but the relative amplification given to soft and loud passages is not affected. The Multitone Electric Company (of 17, New Cavendish-street, W.1) have developed an ingenious device which fulfils the necessary conditions very well, and which acts by allowing part of the output to bias the rest of the amplifier and so to lower the overall amplification. It is now fitted to a three-valve deaf-aid amplifier which is provided as well with the usual manual volume control for adjusting the general intensity of the sound. We have found that it is most efficient in preventing the jarring effect of even very loud noises; it is a valuable addition to these hearing aids and will enable the most sensitive to use them without fear of shock from sudden sounds. Another form of automatic control has

<sup>1</sup> Ministry of Health List 7A. (Revised.) March, 1936. H.M. Stationery Office. 6d.

<sup>2</sup> THE LANCET, 1935, I., 1170.

been evolved by the same firm for use in attachments to wireless sets and other speech amplifiers; this consists of a bridge circuit, of which the resistance of one of the arms changes with the current passing through it. This is incorporated in a unit intended for use with headphones in conjunction with an ordinary wireless set. It is an ingenious device to enable a deaf person to hear the broadcast programmes without making the radio output loud for the rest of the family; it is claimed that such a unit is very useful for practice listening and that some re-educative effect should be expected in favourable cases.

#### THE EPIDEMIOLOGICAL SCHOOL OF PETTENKOFER

LOYALTY to the memory of great men is an agreeable trait of human nature. Even those who are irritated by the Baconian theory of Shakespeare recognise the tribute to a great man. The epidemiological doctrines of Max v. Pettenkofer are of an intellectual value very different from the theories of Donnelly and Mrs. Gallup, but they are no longer popular. A small group of German epidemiologists, headed by Dr. Friedrich Wolter, remain faithful to the doctrines of the Munich master and their publications are always of interest. Dr. Wolter has recently issued two brochures,<sup>1</sup> one on the relation between climatology and epidemiology, the other on the ætiology of *Haftkrankheit*, a term not easily translated, because "gulf disease" would convey too general an idea. That epidemic diseases have long-waved and short-waved time movements has long been noticed; that there are short-waved movements in meteorological events is an equally familiar fact. Modern research suggests secular waves in climatological phenomena; the work of the late Prof. E. Brückner led him to postulate waves of short and long periods, 35 years and 200 years. Dr. Wolter seeks to bring the climatological and epidemiological waves into causal relation. How far he has succeeded is a question which different readers will answer differently. There is certainly nothing unreasonable in supposing that climatological and meteorological changes have important epidemiological consequences; but some readers may hold that diagrams never prove anything and that the arguments have a certain vague magnificence, a little suggestive of the illustrious Sydenham's language on this topic.

Dr. Wolter's second brochure deals with a subject more precisely defined. Twelve years ago much interest was aroused by a remarkable epidemic concentrated upon the Frisches Haff, a narrow gulf communicating with the Baltic. The cities of Königsberg and Danzig are near the shores of this gulf, to the north-east and south-west. Those affected were mainly fishermen and the symptomatology was much like that of the more famous Bornholm disease. There were, however, some differences; in fatal cases, actual degeneration of the muscle-fibres was noted and there was a peculiar pigmentation of the urine. In 1924 there were 600 cases with 6 deaths; in 1925 176 cases with 5 deaths. In the following two years a few cases occurred and then no more until 1932 when there was a fresh epidemic. This "new disease" was christened *Haftkrankheit*, and attracted considerable attention. W. Bachmann published a lengthy study (Arch. f. Hygiene, 1933, ex., 266; *ibid.*, 1934, cxi., 214), leading him to the

following conclusions. Coincidentally with the epidemic there was a mortality of domestic animals, particularly cats, the pathology of the disease in cats being similar to that of the disease in man. The epidemiological evidence did not point to spread by contagion and cases occurred in persons not exposed to the morning mist over the water, to which some had attributed importance. By feeding laboratory animals on fish of various kinds, obtained from the Frisches Haff, especially on the liver of the quappe, evidence of the presence of a toxic substance was obtained. It was, therefore, concluded that the epidemic was due to fish poisoning.

Dr. Wolter seeks to fit this epidemic into its niche as a particular example of a general law. The Frisches Haff is heavily polluted by the sewage of Königsberg and the outflow from various factories. Hence he finds a basis for a subsoil effect. But he identifies the new epidemic with a remarkable outbreak in 1529 in the Haff of Stettin—an outbreak which was part of the epidemiological phenomenon known as the English sweat—and stresses the analogy with the Bornholm disease which has been described in widely separated areas, among others, Wensleydale. Dr. Wolter's epidemiological hypothesis is substantially identical with that of Sir William Hamer. The general setting of an epidemic constitution is determined by climatological and meteorological phenomena in the widest sense of the terms. The particular events are determined by local conditions—for instance, the pollution of the water of the Haff and the consequent changes in the subsoil. The argument is persuasive, if a little vague. Here, however, one does have some concrete facts. Of 502 cases recorded in 1932–33, 314 were of men actually fishing the Haff and 211 of these were taken ill actually on the Haff. Among their wives were 22 cases. Nine other cases occurred in children or persons connected with the fishing industry. Among persons not connected with fishing there were 156 cases; in 39 the subjects had some work on or near the Haff, and another 89 lived within half a kilometre of it. Naturally one would have liked to have some knowledge of the general demography of the district. But if the whole explanation were fish poisoning, it is a little difficult to understand why there should be so great a discrepancy between the sexes. We doubt whether Dr. Wolter's brochures will convince those sceptical of Pettenkofer's theories, but they certainly provide material for argument.

#### PEROXIDES IN ANÆSTHETIC ETHER

It has been thought that convulsions and other undesirable after-effects of ether anaesthesia may be due to impurities and particularly to peroxides in the ether used. Hence it has been considered desirable to use fresh ether from an unopened bottle on each occasion when it is administered. S. R. Wilson, who first described ether convulsions in our columns (1927, i., 1117), was satisfied of their association with impurities in the ether used. Many other theories have been advanced, among them the very interesting suggestion of heat-stroke recently supported (May 2nd, p. 1005) by Drs. Woolmer and Taylor, who give good grounds for excluding impurities in the ether as the causal agent. Further evidence in the same direction was given at the May meeting of the Society of Public Analysts. The investigation was made at the request of the county medical officer for London by the former chemist-in-chief, Mr. J. H. Coste, in collaboration with Mr. D. C. Garratt, Ph.D. The authors confined their work to the effect of peroxides.

<sup>1</sup> Wolter, Friedrich: Seuchenentstehung und Klimaforschung. Pp. 43. Die Entstehungsursachen der *Haftkrankheit*. Pp. 56. (Kleine Hippokrates-Bücherei, vols. v. and vii. Stuttgart, 1936.)

Influenced by the probability on chemical grounds that ether itself would be more volatile than its peroxides, and by the fact that the patient breathes air with the vapour, they studied the evaporation of ether in currents of air and other gases with which it might be administered. They found that when ether was volatilised, either in the dark or in sunlight, in a current of air and the vapour condensed by means of solid carbon dioxide in alcohol, the proportion of peroxide carried over, even from ethers highly contaminated with peroxides, was negligible, although the recovery of ether was almost quantitative. The recovery of peroxide from the unevaporated residue was also almost quantitative and no indication of its formation during evaporation was obtained. This occurred equally whether the air stream was dried before passing through the ether or was of the humidity of the room air. Experiments with an open mask, even when precautions were taken to check loss of ether vapour, yielded poor recovery of ether, but that recovered was almost free from peroxide, whilst 48 to 100 per cent. of peroxide was recovered by washing the mask, after an experiment, with pure ether. The muslin of the mask was found to have no effect on the peroxide content of ether which was dropped on to it. Experiments with a Boyle's apparatus, using nitrous oxide and oxygen in about equal volumes, and allowing about half the ether in the apparatus to evaporate, yielded only very small amounts of peroxide in the condensates, almost the whole of the peroxide being found in the residual ether in the evaporating chamber. The experiments were carried out with ethers so badly contaminated with peroxide that they could not possibly have been used for anaesthetic purpose, and the authors conclude that peroxides themselves are not the cause of the after-effects which may be produced by impure ether. Dr. G. Roche Lynch, who presided, agreed that the rôle of peroxides had been exaggerated.

#### A SYNTHETIC SUTURE MATERIAL

SINCE the time of Lister there has been continuous search for a suture material which would satisfy the requirements of the operating surgeon as to sterility and absorbability while having adequate tensile strength, a non-slipping surface, and pliability. Manufacturers have found it fairly easy to obtain most of these desiderata, but at the sacrifice of one or other of them. A suture embodying all the desired qualities is apt to work out too expensive for general use. A claim is now being made for a synthetic suture material known as Synthofil, which has been tried out in several German surgical clinics.<sup>1</sup> Synthofil, which is a polymer of vinyl alcohol, can be spun in much the same way as an artificial silk fibre, but it has the advantage of being, from the beginning, sterile, strong, and pliable. The threads are perfectly homogeneous and can be made in almost any diameter, thus eliminating the necessity for spinning many threads together to produce a thicker strand. The inventors of the material claim that it can be made in two forms, absorbable and non-absorbable, but the clinical data so far published concern only the non-absorbable type. Synthofil appears not to be deleterious to the tissues, no abnormal reaction occurring around the ligature strand. When absorbed it is partly excreted by the kidneys unchanged and partly broken down in the animal body into non-toxic substances. The amount of polyvinyl alcohol which is excreted as such is relatively

small and from the experiments published it would seem that when used as a suture it is almost entirely broken up in the tissues, so that it cannot be recovered either in the blood or urine. We await with some keenness the publication of further information about the behaviour of the absorbable form of this substance.

#### PREVENTABLE BLINDNESS

THE report on the prevention of blindness drawn up by the standing committee of the Union of Counties Associations for the Blind has now been issued.<sup>1</sup> The membership of this committee includes on the one hand well-known surgeons representing the chief professional organisations concerned with ophthalmology and on the other nominees of the Ministry of Health, the Home Office, and the Board of Education, under the chairmanship of Mr. P. M. Evans, LL.D. A preliminary report, issued in December, 1931, contained a form of report and certificate of what has already been officially recommended for use (1) in the examination of persons for admission to the Register for the Blind, and (2) in the examination of school-children. The present report is divided into six chapters. The first is introductory and deals with the data on which statistical records should be drawn up. It stresses the point that to be of any value all statistical records should be based on the report of specialists in ophthalmology and that a common standard should be applied. The second chapter gives a general account of the eye in health and disease, including a short account of what is meant by errors of refraction and a summary of the chief diseases which are liable to cause blindness. The third chapter contains a detailed description of such measures as exist to safeguard the eyesight from infancy to old age, special emphasis being laid upon the precautions which should be taken to prevent the occurrence of ophthalmia neonatorum and the hospital facilities which to-day exist for the treatment of the disease if prevention fails. The fourth chapter is devoted to a study of occupational disease and accidents which occur in industrial processes. The remaining chapters contain summaries, recommendations, and suggestions for the future, of which the following are among the more immediately important.

The committee stresses the importance of a comprehensive and adequate system of antenatal supervision as a means of safeguarding the eyesight of both mother and child. It is encouraging to note that the proportion of women attending antenatal clinics in England, expressed as a percentage of total notified births (including stillbirths), rose from 27 per cent. in 1930 to 43 in 1934. The importance of close liaison between the antenatal work of an authority and the centres or clinics for the treatment of venereal disease is obvious, but where it is possible to arrange for women and children to receive treatment for venereal disease in association with a maternity and child welfare clinic rather than at the recognised venereal disease centre such an arrangement is to be preferred. Should ophthalmia develop in the newly born, the ideal to be aimed at is the admission of mother and child together into a hospital ward where the services of an ophthalmic specialist are available. In prevention the first essential is the proper cleansing of a baby's eyes at birth; the committee recommends, but does not insist on, the

<sup>1</sup> v. Brandis, H. J., König, W.: *Zentralbl. f. Chir.*, Reprint from No. 7, 1936; Braun, B.: *Melungen*, Inaugural Dissertation, 1936.

<sup>1</sup> Report on the Prevention of Blindness by the standing committee on the prevention of blindness of the Union of Counties Associations for the Blind. From the secretary of the committee at 66, Victoria-street, London, S.W.1. 2s. 6d.

application of 1 per cent. (but not stronger) nitrate of silver, these of which should be included in the midwife's training. The services of an eye specialist should be available for isolation hospitals, especially in cases of measles. Coming to school age, the committee recommends the examination of every child's sight as soon as possible after entry into school. The treatment of eye diseases at clinics should be carried out under the supervision of an ophthalmic surgeon. In the care of myopia the part played by the special school for the partially sighted is regarded as a most important problem which needs further consideration. The committee would fasten on local authorities the responsibility for ophthalmic supervision of all partially sighted children after leaving these schools, and any such scheme should apply also to children leaving the elementary school with serious eye defects. Miner's nystagmus, not being a cause of blindness, did not come within the purview of the committee, but the committee considers the risk to the eye in metal working, in chemical processes through the splashing of chemicals, and in stone dressing. One main difficulty is the prejudice of the workmen themselves against the wearing of goggles. In some instances their objections had good reason and improvements in the type of goggles themselves are suggested. A form of gauze veil advocated by the late Mr. Bernard Cridland, an original member of the committee, appears to have been an efficient substitute for goggles where it has been tried. Among agricultural workers most of the injuries to the eye happen during hedge cutting and trimming; for these as well as for other accidents occurring in country districts the main difficulty is to procure timely expert advice. This enhances the need for education in preventive measures, such as wearing goggles.

The value of this report is increased by the mass of corroborative detail in the appendices. Many of the problems on which it touches are still unsolved and the report points to the directions in which measures of reform are most urgent. It is a worthy successor to the departmental committee's report of 1922.

#### IN PERSON OR BY POST

TROUBLE of one kind or another is the raw material of the doctor's trade; he deals in it all day, and when he is off duty he does not like his friends and family to talk that kind of shop. This is one reason why medical charities are none too well supported; the busy practitioner gives much professional time and thought to people in distress, and he feels that he has done his bit when his day is over. A regrettable result, however, is that the Royal Medical Benevolent Fund, which every doctor ought to support, can offer no more than £40 a year to any of its beneficiaries—no matter how badly off. As Sir Thomas Barlow has pointed out, such an allowance, in the changed needs of the century, is inadequate, and those familiar with the work must feel thankful for the existence of the Ladies' Guild attached to the Fund which makes the little money go further and supplies help more valuable even than cash. Last year, as the annual report shows, there were more new cases than ever before—a fact both encouraging and discouraging. "It is not so much the thought of the poverty but the realisation of the dreariness of the lives of so many of our beneficiaries, which haunts me," writes the chairman of the case committee, and the Guild is not so preoccupied with coal, medicine, spectacles, dentures, convalescence, education, and

clothing that it does not also think of occupation—something to pass the hours of inactivity which must be peculiarly dreadful when spent in unaccustomed poverty. It is something to know that if there is all this unhappiness there are also many who are trying to relieve it. The Guild asks especially for more members among the younger doctors' wives, and while funds are always needed—especially for such objects as dental aid—there is hardly any domestic gift for which a use cannot be found. Clothes, curtains, carpets, furniture, blankets, towels, toys—all these, as we have said before, will be gratefully received if sent to the Ladies' Guild of the R.M.B.F. at B.M.A. House, Tavistock-square, London, W.C.1.

#### HUMAN PERSONALITY

IN the Salmon memorial lectures, now published in book form,<sup>1</sup> Prof. Macfie Campbell makes a plea for the direct study of human personality. The more impersonal investigations of human beings, made by the experimental or the comparative method, leave gaps which cannot in his opinion be filled otherwise than by a broad historical approach to man as a social unit, revealing in his aberrations from normality the deeper forces within his nature. The clinical psychiatrist has more to contribute to the understanding of human personality than a knowledge only of the symptoms and treatment of illness. He need not yield his territory to the laboratory worker or other specialist. Schizophrenic illness supplies a paradigm for the demonstration of how the psychiatrist can bridge the gap between normal and abnormal, and bring light to bear upon the structure of human personality and the forces that mould it. It would be difficult to find elsewhere so readable and persuasive an argument for the prosecution of the broad psychobiological method of study in clinical psychiatry and psychology.

THE joint congress of the Royal Institute of Public Health and the Institute of Hygiene opens in Edinburgh on Tuesday next, and will continue throughout the week.

THE next session of the General Medical Council will open at 2 P.M. on Tuesday, May 26th, under the presidency of Sir Norman Walker.

H.M. King Edward VIII., following the example of his royal predecessors from William IV. onwards, has given his patronage to the Royal Society of Medicine.

<sup>1</sup> *Destiny and Disease in Mental Disorders*. By C. Macfie Campbell, M.D., Professor of Psychiatry, Harvard University. London: Chapman and Hall, 1935. Pp. 207. 10s. 6d.

COMMONWEALTH FUND FELLOWSHIPS.—Commonwealth fellowships in medicine have been awarded to Dr. W. M. Honeyman and Dr. M. S. Jones. Dr. Honeyman intends to work at Columbia University and Dr. Jones at the University of Pennsylvania.

GRADING OF MILK.—The new Milk (Special Designations) Order made by the Minister of Health comes into operation on June 1st. As explained in our issue of May 2nd (pp. 1016 and 1036) the existing four grades of milk will be replaced by three grades designated tuberculin-tested, accredited, and pasteurised. A memorandum setting out in non-technical language the effect of the Order and the way in which it will work has been issued by the Ministry (Memo. 197/Foods) and may be had at 3d. from H.M. Stationery Office or through booksellers.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### CI.—CONGENITAL HEART DISEASE

In congenital heart disease the abnormality of the heart is a stationary lesion, and we are little concerned with such possibilities as relapsing or progressive infection or increasing degeneration. Consequently in trying to foretell the outlook for any individual patient we are in the position of being able to base our opinion, with rather less doubt than in acquired heart disease, upon those fundamental points which govern prognosis in all forms of heart disease. These are, first, the compensatory changes in the heart itself developed to overcome the handicap of the congenital cardiac lesion; and secondly, symptoms of failure on the part of the heart to maintain the circulation adequately, particularly in response to effort.

On the other hand, although the cardiac lesion remains stationary, with the growth in the development and activity of the child the calls upon the heart to maintain the circulation are increased, and so the effect of the congenital abnormality becomes relatively greater. Even though the growth of the child may be automatically retarded, as in cardiac infantilism, it is too great for the heart to respond to, and premature death results. This is the common course of events in such patients as show early signs and symptoms of cardiac inadequacy.

Changes pointing towards improvement as the child grows are quite exceptional in congenital heart disease. A baby who is severely cyanosed at birth may become rather less so in the first year or so of life, but such an improvement is probably never sufficient to make much difference to the ultimate survival of the child. In a few instances a harmless murmur, usually that associated with a patent ventricular septum, will disappear in the first five years of life. Although this may be a matter of comfort to those concerned, it is not of real importance in prognosis.

In the individual case, where the congenital anomaly is of clinical importance there will be compensatory changes in the heart, chiefly those of enlargement to the right, with (in severe cases) precordial bulging and even engorgement of the liver. Of still more importance, because easier to appreciate in the milder examples, will be the occurrence of symptoms of cardiac inadequacy. These consist of shortness of breath and cyanosis. In the milder cases, where the reserve power of the heart alone is affected, these will appear only in response to effort; but in the more serious types the power of the heart is diminished even when the patient is at rest and the symptoms are persistent, although increased by exercise. Some care must be taken in judging the accuracy of a history of such symptoms, for where an uneducated mother is asked by each doctor who examines her child if it is short of breath or goes blue on exertion, it is not unlikely that in the course of years these expected symptoms will be imagined. Personal observation by the doctor is therefore of more value. The commonest congenital lesions associated with cyanosis are stenosis of the pulmonary artery and patency of the foramen ovale. In pulmonary stenosis there is enlargement of the right side of the heart with a harsh systolic murmur most audible at the pulmonary area. At the point of the maximum intensity of the murmur there is a systolic thrill. Patency of the foramen ovale is less common and

much more difficult to diagnose than pulmonary stenosis. It is not as a rule associated with any murmur and its presence has to be surmised to account for unexplained cyanosis of cardiac origin.

In a great many instances, particularly amongst children who have survived to school age, the most careful survey will show that the congenital lesion is not handicapping the heart in any way at all. Where the circulation is maintained efficiently in all circumstances, and the heart shows no signs of compensatory change, these facts must be taken to govern the situation, and the mere presence of some abnormal sound in the heart must be regarded as quite a minor matter. It is hardly sufficiently realised in how many examples of so-called congenital heart disease the function of the heart is unimpaired and the condition negligible. In those who have reached school age this type predominates, and at later ages its predominance becomes greater and greater. The two common forms of congenital cardiac abnormality which are characterised by the presence of murmurs with no trace of cardiac insufficiency are patent ventricular septum (*maladie de Roger*) and patent ductus arteriosus, when they exist as solitary lesions. In the first there is a systolic murmur audible over most of the cardiac area, including the apex, with its maximum intensity in the fourth left interspace next the sternum, at which point a thrill may sometimes be felt synchronising with the murmur. In patent ductus arteriosus there is in early years a systolic bruit in the pulmonary area, unaccompanied by cyanosis; later a diastolic bruit develops, giving the characteristic continuous "mill-wheel" murmur. A triangle of dullness may be elicited above the third left rib next to the manubrium, and opacity in this area may be detected radiologically.

#### SUMMARY

The prognosis in congenital cardiac abnormalities depends upon the presence or absence of evidence of cardiac insufficiency. Its presence is shown by shortness of breath and cyanosis; where these are persistent the outlook is worse than where they appear only in response to effort. In the group with cardiac insufficiency adult life is not likely to be reached. There is a heavy death-rate in infancy, and only comparatively few survive to school age. As the child grows the handicap to the heart and the tendency to respiratory complications increase. An occasional case of marked cyanosis may be seen in adolescence; in such instances the abnormality consists probably of combined pulmonary stenosis and patent interventricular septum. On the other hand the cases in which there is no evidence of cardiac insufficiency are more numerous than is generally recognised. In such the murmur is discovered accidentally, and the less stress laid upon it the better. Such children should not be sent to special schools or handicapped by unnecessary restrictions.

In the rarer forms of congenital heart disease prognosis should be attempted on the general lines laid down in the opening paragraph of this article. It is thought that in all forms of congenital heart disease there is an added risk of acquired heart disease, particularly of malignant endocarditis.

Physician to St. Mary's Hospital and the Paddington Green Children's Hospital, London.

## SPECIAL ARTICLES

**THE RESULTS OF  
COLLOIDAL SELENIUM TREATMENT  
OF CANCER**

REPORT OF AN INVESTIGATION BY THE MEDICAL  
COMMITTEE OF THE ROYAL CANCER HOSPITAL, S.W.3\*

In 1934 Dr. A. T. Todd published the results of his treatment of malignant disease by Colloidal Selenium, and the claims made were so striking that we considered it of the utmost importance that the method should be tested independently. At our request, therefore, Dr. I. P. Murray was appointed to treat a series of cases by Dr. Todd's method under the general supervision of the medical staff. Dr. Murray took up her appointment on Oct. 1st, 1934, but before employing the treatment she visited Bristol and spent several days there learning from Dr. Todd the details of his technique. Since that time Dr. Murray has treated under our supervision 70 patients with malignant disease along the lines laid down by Dr. Todd, and the results of this work follow.

During the ten months October, 1934, to August, 1935, 70 cases have received selenide treatment at the Royal Cancer Hospital. Records were kept of every case, and filed according to the selenide number which was also stamped on the registrar's records, so that the different sets of notes may be correlated. These records include a clinical history of the case, measurements of the growth where possible, and diagrams with a graphic record of the weekly blood count and dosage of colloid and X rays. No selection of cases was made; all of them were in an advanced stage of the disease, and with one exception all had had previous surgical, radium, or X ray treatment. Cases were treated both as in-patients and out-patients. From the out-patient clinic patients were seen by their particular physicians or surgeons at definite intervals.

TECHNIQUE

In certain cases a preliminary "toilet operation" was carried out (surgical removal of a reasonably large part of the mass). The treatment aimed at for each patient was: (a) ionisation course (for a period of 8 weeks); (b) radio-active selenide course (for a period of 3 weeks); (c) alternation course (for a period of 4-6 months); but certain patients did not live long enough to complete the treatment; others refused to complete it and yet others began treatment so late in the investigation that the treatment was not completed during the period under review.

(a) During the ionisation course eight weekly injections of sulphur selenide were given, followed in 48 hours by X ray treatment, each dose equal to 75 r. giving a total in 8 weeks of 600 r. The initial dose of sulphur selenide was 1 or 0.5 c.cm. and was subsequently increased weekly by 1 or 0.5 c.cm. or reduced, according to whether there had been any previous reaction.

(b) Three weekly injections of radio-active selenide were given, commencing with 1 c.cm. and increasing weekly by 1 c.cm.

\* The members of the Medical Committee are Lord Horder, Mr. W. Miles, Sir James Dundas-Grant, Dr. H. Robinson, Mr. R. H. Jocelyn Swan, Dr. Stanley Wyard, Mr. Cecil Rowntree, Mr. P. P. Cole, Mr. C. A. Joll, Mr. C. E. Shattock, Mr. A. Lawrence Abel, Mr. R. C. B. Ledlie, Dr. C. O. Worster-Drought, Dr. H. W. Gordon, Mr. D. H. MacLeod, Mr. C. D. Shapland, Mr. W. A. Mill, Dr. T. B. Vaile, Prof. E. L. Kennaway, and Prof. J. M. Woodburn Morison.

The duration of the different courses was not rigidly adhered to, for in certain cases it was thought necessary to prolong the ionisation course.

(c) During the alternation course the patient was given alternate weekly injections of sulphur selenide and radio-active selenide for a period of 4-5 months. Treatment was then discontinued for a short period.

Six hundred and thirty-six injections were given over a period of ten months. In every case a rigor occurred, either immediately or up to three hours following the injection, whenever a sufficiently large dose of sulphur selenide was injected.

Dr. Todd defines<sup>1</sup> "a true focal reaction" as "a definite but moderate aggravation of the symptoms produced spontaneously by the neoplasm" and states that this reaction "sets in 3-12 hours following the injection." A "true focal reaction" was never seen in this series of cases, even with large doses of the colloid.

One case of sulphæmoglobinæmia occurred during the administration of sulphur selenide.

This was in a female, aged 49 years, with advanced carcinoma of the anal canal. Owing to poorness of the general condition no colostomy had been performed. The bowels were kept freely open with large doses of laxatives and daily rectal irrigations. Selenide treatment was commenced on March 4th, 1935. On April 8th, 1935, the patient was noticed to be a leaden-blue colour, especially marked about the lips, finger-tips, ears, and mucous membranes. She had received six injections of sulphur selenide, the total amount of colloid given was 23 c.cm., which contains 0.092 g. of sulphur, and X rays equal to 450 r., over a period of six weeks.

Specimens of blood and urine were examined spectroscopically by Mr. W. V. Mayneord, D.Sc., physicist to the hospital, who made the following report: "The specimen shows a very well-marked abnormal band in the red, together with some broadening of the green line of the oxyhæmoglobin pair. There is no obvious band in the blue. On comparison with standard spectra this is very suggestive of sulphæmoglobin. No evidence of sulphæmoglobin in the urine."

No further sulphur selenide was given for four weeks: then 3 c.cm., which contain 0.012 g. of sulphur, were injected, and the blood was examined after a period of one week. Dr. Mayneord now reported: "The blood shows a very strong absorption band in the red at a mean position of 628  $\mu$ . Artificially prepared human methæmoglobin shows a band at about 640  $\mu$  and of different structure. Sulphæmoglobin prepared from human blood gave a band of mean position 627  $\mu$ . From the general nature and position of the absorption band in the patient's blood it appears therefore that the absorption is probably due to sulphæmoglobin."

The selenide treatment was discontinued and the patient's colour gradually improved. On June 26th, 1935, acute obstruction supervened and the patient died eleven weeks after the last injection of sulphur selenide.

DRUG TREATMENT

Each patient was given the following: (a) Dry thyroid extract 1/10 grain daily. (b) Sodium iodide 5 grains three times daily. (c) Mist. calci. thiosulph. 1 oz. three times daily. (d) Radiostoleum 6 minims daily.

The analgesics used were Allonal; Mist. aspirin, phenacetin and caffeine; Tab. amidopyrin co.; Dial. Opiates were given only to patients in extremis. Of the above drugs, mist. calci. thiosulph. and sodium iodide were in some cases discontinued owing to their laxative action.

<sup>1</sup> Brit. Jour. of Surg., 1934, vol. xxi.

**PATHOLOGICAL INVESTIGATIONS**

(a) *Blood counts.*—Weekly blood counts were performed on all patients during the ionisation course, and on alternate weeks during the radio-active selenide and alternation courses, in order to ascertain the reactivity of the patient, and, accordingly, the amount of colloid to be given.

Dr. Todd has stated<sup>1</sup> that “an increase, absolute, not relative, of the small lymphocyte and eosinophil cells is favourable” and to be regarded as evidence of reactivity. Three hundred and seventy-eight total differential leucocyte counts were carried out during the period of ten months. Weekly normal control leucocyte counts on members of the staff, estimated over a period of seven weeks at corresponding hours of the day, have shown considerable variation (1) between individuals, and (2) according to the time of day at which the count is made—e.g., relationship to meals. Charts of leucocyte counts performed on patients receiving the selenide treatment showed no correlation between the dose of colloid given and the corresponding blood count obtained in any individual case. It seems probable that the leucocytosis is due to septic absorption from the fungating growth independently of any effect of the colloid injected. It would seem also that the increase of lymphocytes is in direct proportion to the total leucocyte count, and in fact no absolute increase occurs.

(b) *Blood lipase.*—Blood lipase estimations by the Rona technique were performed monthly when possible. It had been previously claimed<sup>1</sup> that the blood lipase tends to be high in cancer, but not invariably, and that a lowering level is usually favourable, and an increasing level usually a sign of advancing growth.<sup>1</sup> Sixty-two blood lipase estimations were performed over the period of ten months. The normal blood lipase has an index of 15. An error of +3 or -3 is probably due to alteration of surface tension with varying atmospheric pressure. Patients with progressing growths showed a slight rise in the lipase level followed by a definite fall, and this might have been read as an index of regression of the tumour although, in fact, on clinical grounds they were obviously progressing. The conclusion reached is that this method of control is not of any great value.

(c) *Blister test.*—The cytology of the blister fluid produced by the application of a standard-size cantharides plaster has also been regarded as a test of reactivity of the patient's tissues to a standard irritation since “the findings of a good take with increase of endothelial, lymphocyte and eosinophil cells is also favourable. Increase of epithelial cells is said to be of no importance.”<sup>1</sup>

Fifteen blister-fluid counts were performed. In these 15 cases it was found that the application of a standard-size cantharides plaster did not always produce the required blister; also it was extremely difficult to obtain satisfactory specimens of blister fluid on which an accurate cell count could be performed.

**RESULTS OF TREATMENT**

Although the treatment is long and tedious most of the patients coöperated in every possible way. Apart from the rigors which may occur the treatment is painless if the injection is given directly into a vein.

Of the 70 cases treated, 41 have died (see Table II.); 21 are still under treatment; 7 have refused further

treatment; and 1, who received merely prophylactic treatment, is still without evidence of recurrence (see Table III.).

The Medical Committee have pleasure in acknowledging Dr. Todd's courtesy in demonstrating his method of treatment to Dr. Murray. They wish also to record their appreciation of the care and zeal with which Dr. Murray has performed her duties, and the skill with which she has carried out a not always easy technique.

PORTH HOSPITAL, GLAMORGAN.—On May 12th extensions to this hospital were opened which included an X ray department and 28 bed-rooms for the nursing staff. Sir William Thomas has given 1000 guineas to endow a bed in memory of men who fell in the war.

DR. BARNARDO'S HOMES.—At the annual general business meeting of Dr. Barnardo's Homes, National Incorporated Association held on May 13th, the report showed that 118,113 destitute boys and girls had entered the homes to Dec. 31st last. A total of 15,988 children and young people were dealt with during the year, and 1464 boys and girls and babies were admitted—1332 permanently and 132 temporarily. The number in residence at the end of the year was 8182. These homes, it is claimed, have no red tape and no waiting-list; the need of the child is the only consideration. The address of the association is 18, Stepney-causeway, London, E.1.

## INTERNATIONAL CONGRESS OF PHYSICAL MEDICINE

(Continued from p. 1153)

At the meeting of the section of kinesitherapy on May 13th, held at the house of the Royal Society of Medicine and presided over by Dr. JAMES B. MENNELL, a paper was read by Major C. R. DUDGEON on

### Low Backache

He said that he proposed to make a general survey and to select certain points for particular attention. In the past, cases of low backache had been treated by applying hot irons, belladonna plasters, and liniments, and by all sorts of people; by the time the cases came to the practitioner of physical medicine the primary symptoms had become masked, and secondary symptoms had become well established. It was thus often very difficult to find out the nature of the primary causal factor in a given case. If low backache had lasted a considerable time, one condition which frequently became engrafted was that of neurasthenia, due to the long-continued pain. So obtrusive was the neurasthenia sometimes that the primary backache was almost forgotten. Yet it was the latter on which attention should be concentrated, because no efforts directed to curing the neurasthenia were likely to succeed until the cause of the backache had been discovered and treated. In an acute case it was often very difficult to arrive at a diagnosis, because the patient's only answer to the various manipulative efforts to localise the trouble was: "that hurts." When the patient presented himself to the physician he had probably been brought straight from bed to keep the appointment, and on his journey had sat on hard and uncomfortable seats in 'bus or train; and it was then good practice to put him on a bed for a time and apply infra-red rays or hot wax, and some massage for half an hour. The patient's relief was often so great that subsequent examination was much more revealing. Major Dudgeon attached considerable importance to an accurate history, particularly as to habits or unusual occurrences; not the long story of how someone left orange peel on the pavement and the twist the patient got from stepping on it, but rather an account of his general mode of life, or any periodic strains he had undergone. An instructive example was the following.

A woman of middle age complained of backache recurring on and off for several years. She said that her activities consisted of ordinary household duties. The diagnosis made was mild sacro-iliac strain, and the treatment was successful. But she returned with recurrences time and again. Eventually, after close questioning, it was ascertained that occasionally she did some glove-making at home, and to work the machines she had to adopt a cramped attitude for considerable periods. The attacks coincided with the bouts of glove-making, and when she followed the advice to stop this work the attacks of pain also ceased.

Low backache could often be classed as an occupational disease. On a cold winter morning backache might follow the laborious cranking of a motor-car. Some other causes were not so obvious. Motoring papers had had much to say recently about the need of having "anatomically shaped seats"; some recommended special rubber sponges which fitted into the back, pneumatic cushions, and so on. Generally speaking, the driver of a luxurious modern car took up a lolling attitude, probably with his lumbar curve reversed. At a stop he might get out,

stretch himself, and complain of backache; and at the end of a long journey he might be so distressed that his condition called for treatment. Passengers were not so much affected as they could relax and change their postures. The driver bestowed upon himself a series of small traumata in a false position, a factor being frequent application of the brake pedal. The pain in all but one of the cases of this kind which Major Dudgeon had seen was on the right side. One case of severe pain in the region of the fifth lumbar nerve was due to the tilt of a driver's seat, the springs having given way on one side. Previous treatment had been ineffective, but when the seat was put right his pain was cured. Mining was an occupation in which these cases occurred frequently; another was in small printing establishments, in which a man might perform a high treadle action to motivate a fly-wheel. Nurses who lifted heavy patients also tended to suffer from low backache. During the war a number of cases of so-called lumbago were due to the adoption of a stooping attitude by the occupants of shallow trenches who were sometimes burdened with a heavy pack. In cases of recurrent backache it was always wise to search for summations of slight traumata extending over considerable periods.

Treatment of low backache could be grouped as: (1) means to increase or to restore mobility; (2) means to prevent undue mobility or malposture where this was diagnosed as the cause of the pain; (3) means to stimulate local metabolism and decrease spasm.

*Means to increase or restore mobility.*—Various forms of manipulation and gymnastics were included in this group. Manipulation could be divided into (a) forced manipulation, usually under anaesthesia, and (b) the more gradual forms, including the loosening by shaking or otherwise of various parts. It was easy to abuse manipulation; in some conditions it was not only contra-indicated, but useless. A patient with fibrositis, for instance, should never be manipulated. Often manipulation was used as a shot-gun when a target rifle should have been employed. "Shaking loose" and gymnastics played but a secondary rôle in the treatment of low backache conditions. After undergoing manipulation, especially extensive manipulating, the patient should be given a respite from all weight-bearing functions; his musculature could be maintained in a vigorous condition by giving him functional exercises to carry out without weights. The muscles of the lower back were so strong, and spasm in them was so often present that, usually, it was unsatisfactory to manipulate them except under anaesthesia so deep as to ensure really good muscular relaxation. Physical training and re-education were of the first importance in the treatment of the low backache in which wrong posture was a definite factor.

The *prevention of malposture* should include all kinds of causes. Mobility might be excessive, as in constantly recurring sacro-iliac strain, or less than normal, as in patients with long transverse processes of the fifth lumbar vertebra, one of which impinged on the ilium. The aim should be to limit this movement by providing a support, or, as in lordosis, to properly distribute the strain. Webbing, with back plates, could be used, and excellent types of surgical belts and corsets were now available, which might be modified to suit the particular case. These supports must be made of inextensible material; the modern elastic or suspender belts were useless. The belt should fit firmly over the pelvis and possess means of rapid adjustment, so that most of the

counter-pressure was taken from that part of the belt or corset which was below the anterior superior spine—the only firm origin of support. Modifications could be carried out by means of front and back plates of celluloid, ebonite, or supports, such as those made of red fibre, which could be made up on the spot and fitted with a strut. Women of childbearing age who had suffered considerably from low backache should be directed to report pregnancy, for low backache was likely to recur as lordosis increased. A belt fitted with a generous back plate and adjustable to conform to a progressively altering contour, should be fitted and every effort should be made to maintain the lumbar curve during confinement and at the puerperium.

For the *stimulation of local metabolism and decrease of muscular spasm* Major Dudgeon favoured the use of pneumatic cupping which he had used with great success. The affected area of the back was thickly smeared with vaseline, and the cup was applied and then lifted, bringing the skin with it, when a sliding movement of the cup was carried out. The process might occupy ten minutes, at the end of which a definite hyperæmia was present over the area; this treatment was useful for abolishing or reducing spasm and coccydynia. The wax pack, introduced from Sweden, was also valuable. A spongy cellulose sheet which had been impregnated with wax by the makers was put on the back of the patient and covered with an electric heater. It acted in the same way as a wax bath, but without its inconvenience. The wax was left on after removing the source of heat. Muscular spasm was thus reduced, and the skin was left in an ideal condition for subsequent treatment. If cases of low backache radiating from a single sensitive spot did not yield to ordinary measures, ultra-violet rays up to the third degree of erythema might be efficacious.

Dealing with the question of coöperation by the patient, Major Dudgeon said sometimes the latter caused or aggravated the painful condition by attempts to help himself, for example, by doing gymnastics. For correction of posture or maintenance of mobility, the patient's help was essential. The type of bed used should be ascertained. A sudden change from a sagging feathered bed to a more rigid mattress might cause pain. Sometimes a lumbar pillow, or one between the knees was helpful. Sufferers from low backache should be told never to sit in a lounge chair, nor to loll in any chair, and not to choose the corner seat in a train.

Mr. A. L. P. JEFFERY demonstrated, by means of ingenious models, the mechanics of a number of the deformities and malpositions of patients complaining of low backache. He spoke of the importance not only of remedial postures and exercises, but of correct deportment and of a recognition of the lines of stress and weight-bearing. He described and demonstrated his methods of teaching students the essential points in the differential diagnosis of low backache.

On Wednesday, May 13th, with Dr. E. P. CUMBERTON (London) in the chair, a meeting of the section of electrotherapy was devoted to a series of papers on

#### SHORT-WAVE DIATHERMY AND ARTIFICIAL FEVER THERAPY

Dr. E. SCHLIEPHAKE (Giessen, Germany) gave an account of Ultra-short Waves in Internal Medicine. He said that ultra-short waves might be expected on theoretical grounds to have special depth effects and also specific effects. An increase of depth effect

had been found in the homogeneous di-electric but was much more pronounced in the substrata. Thus the distance of the electrodes from the skin determined the ratio of the heat produced in deep-lying areas and in the surface. The short-wave field directly affected certain ions, molecules, and colloidal suspensions, while adjacent parts of a different nature might be passed over. Hausser, Kuhn, and Giral had shown that side chains within a complex molecule might be affected independently. In fresh muscle an increase of hydrogen-ion concentration had been produced by short-wave penetration and the shorter the wave the greater the increase produced. Short-wave therapy was not just heat therapy. In some cases immeasurably small heat development had lasting curative effects; in others improvement had resulted where the use of heat and diathermy might have led to aggravation. The speaker had been the first to demonstrate the special effect of ultra-short waves on boils and carbuncles; demarcation, fusion, and expulsion of necrotic material was hastened by this means. He had treated 40 cases of pleural empyema and abscesses of the lung by short-wave therapy. Only two had died and in them the original disease had been peritonitis. These results were to be compared with a previous mortality of over 60 per cent. with medical and over 35 per cent. with surgical treatment. The dosage was especially important; dosage too weak had no effect, while overdosage broke down the leucocytic protective wall and the blood stream might become infected. Dr. Schliephake had had favourable results from treating rheumatism and arthritis without raising the temperature excessively, and he attributed this to the wave-length (12 metres) which he had used. Other investigators had used 30 metres. Only very weak doses should be used in the treatment of vascular diseases. Good results had been reported in angina pectoris, myocarditis, arterio-sclerosis, and spastic gangrene. Other promising fields were hypertrophy of the prostate, certain forms of tuberculosis, diabetes, and diseases of the nervous system. The scientific investigation of these fields would have to be pursued extensively and diligently without undue optimism.

Dr. RICHARD KOVACS (New York) spoke on the Clinical Comparison between Diathermy and Short-wave Diathermy. He said that in the United States short-wave diathermy had been introduced by the manufacturers. Small concerns with no experience of electro-medical apparatus had rushed into a promising field and sales propaganda had been unscrupulous. The consequence was that many inexperienced physicians had been saddled with apparatus which was both unstandardized and dangerous in its possibilities. Though competent men had by now carried out research and clinical work, the place of short-wave therapy would not be determined for several years. Short-wave diathermy differed from conventional diathermy in its greater powers of penetration and heating. In their effect on purulent skin infections he believed that short waves resembled other ways of heating and could not be considered specific. He considered short-wave diathermy safer than conventional diathermy though it had dangers—e.g. burns might result from a condenser effect by droplets of sweat. No flexible metal electrode should be used without interposition of a pad; coagulation at a depth without a burn on the surface was a further possibility. Short-wave diathermy was convenient in that the electrodes could be applied quickly and treatment could be

carried out over curved surfaces, wounds, and through plaster casts. The fact that this treatment could be administered through clothes, although advantageous to the expert, might tempt the beginner to carelessness and neglect of the rule that parts must be inspected before and after treatment. Conventional diathermy had the great advantage that in local treatment the dosage could be roughly gauged by a millimetre, and that the same dosage could be repeated. In short-wave treatments the skin sensation of the patient was the only guide for regulating current input. There was no proof that the maximum dosage was passing and there was no safeguard against burning of the skin or against damage to deeper parts in cases of deficient skin sensation. This crude method of dosage regulation was the greatest drawback of short-wave therapy, and until it was remedied many local treatments would be administered on the principle of hit or miss. In short-wave fever treatment the rise of temperature was a reliable guide. Many patients liked the absence of all faradic sensation in short-wave treatment. The speaker had had intelligent patients who doubted whether the short waves were as effective as conventional diathermy. He thought that some beneficial effects of diathermy might originate from reflex action through the skin. From the standpoint of ultimate results short-wave diathermy gave no proof of better results in the cases for which diathermy was usually of value.

Dr. W. M. SIMPSON (Dayton, Ohio) described his experience of Artificial Fever Therapy of Syphilis and Gonococcal Infections. He said that since the introduction in 1919 of malaria treatment for general paralysis of the insane the therapeutic effects of fever had come to be recognised. In a search for means of inducing fever he had tried hot air, hot lamps, hot blankets, and then short-wave therapy, and, in order to avoid burns from the condenser effect of sweat droplets during this last form of treatment, he had passed a current of hot dry air over his patients. An accidental omission to switch on the wave therapy one day had revealed that a rectal temperature of 106°–107° F. could be maintained by the hot air blast alone. He had therefore designed an apparatus which passed hot air of regulated flow, temperature, and humidity over the patient. The patient lay with only his head outside the apparatus; he was given from 2–5 litres of 0.6 per cent. saline, iced, to drink to replace the loss by sweating. Treatment had been given to 191 cases of syphilis and gonorrhoea. Twenty-one out of 27 cases of G.P.I. had obtained complete clinical remission; they had received injections of arsenic or bismuth 20 minutes before each of ten weekly sessions of artificial pyrexia. Each session lasted five hours and the course was followed by further 20 weekly injections of antisyphilitic preparations. Successful results had also been obtained by similar treatment of primary chancres; and the crisis of tabes had been relieved. For the treatment of gonococcal arthritis, salpingitis, and urethritis a rectal temperature of 106°–107° F. was induced for 5–7 hours twice weekly, and had good results. He considered the short-wave therapy apparatus too dangerous to be in the hands of any without expert training.

Dr. F. LOBRE (Paris) spoke about the Treatment of Salpingitis, Metritis and Gonococcal Metritis by Ultra-short Waves. He had concluded from experiments that the diverse effects obtainable by ultra-short wave therapy depended on their mode of application and were attributable to a transformation of the magnetic field into a current within the tissues.

Different cases required different applications of the waves; metritis and gonococcal metritis required treatment for many hours, gonorrhœa in man was treated by a local temperature of 41° C. for 10–12 hours, while salpingitis responded best to two-minute doses which were followed by reaction.

Dr. A. HALPHEN (Paris) read a paper by Drs. J. Auclair, M. R. Dreyfus, and himself on the Treatment of Gonorrhœa by Short-wave Heat Therapy. He said that the susceptibility of the gonococcus to heat was generally known. Heat therapy was therefore rational, and short waves seemed the best heating agent. Local treatment, although not suitable for gonococcal arthritis since this was but a manifestation of a systemic disease, could be used for all genito-urinary organs which could possibly harbour gonococci. By means of a special apparatus they had been able to effect a cure in almost all such cases, or at least to control the disease within a week of starting treatment. A temperature of 41° C. during 10–25 hours was essential. The method could be applied to acute or chronic urethritis and their complications in man, to gonorrhœa in women, and to vulvo-vaginitis of children.

Dr. W. D. McFEE (U.S.A.), discussing Electropyræxia, spoke of the use of this therapy to induce hyperæmia, to quicken chemical reactions in the body, and to foster movement of leucocytes. He said that fever therapy appeared to arrest the progress of cerebro-spinal syphilis and tabes. It was of value in some cases of gonorrhœa, more especially in those chronic cases where other treatment had failed; in disseminated sclerosis, asthma, and angiospasm. Contra-indications included recent tuberculosis, an age greater than 60 years, cardiac or renal insufficiency, and advanced dementia in general paresis.

Dr. W. KERR RUSSELL (London), speaking about Electropyræxia produced by Short and Ultra-short Waves, gave a detailed account of his experience of these methods during the past year. The ultra-short wave apparatus generating waves of 12 metres, although fitted with an accessory hot air circulating system, had given some difficulties: burns had occurred not only from accumulation of sweat but also from overheating of the sacrum; sometimes movements of the hands had produced sparks; and once extensive burning had been caused in a case of disseminated sclerosis with impaired sensation. The patients were admitted to hospital the day before or early on the day of treatment. The usual observations were made, including taking the blood pressure and an examination of the urine. No solid food was allowed on the morning of the treatment day and an enema was administered. Thick woollen socks and sponge rubber pads on the heels were necessary to prevent pressure sores. Restlessness during treatment was countered by Omnopon. The pulse was the best indication of the patient's condition, and signs of circulatory or respiratory embarrassment demanded that treatment should be stopped. The temperature should be kept below 107° F. for fear of heat-stroke. One fatality had occurred in a woman of 24 suffering from the parkinsonian syndrome; she had died about ten hours after receiving 1½ hours' treatment. Forty-nine cases had been treated, which included 24 of disseminated sclerosis, 12 of rheumatoid arthritis, and others of encephalitis lethargica and paralysis agitans, *B. coli* cystitis, asthma, gonorrhœa, chorea, and brachial neuritis. It was too early to judge the results. Some cases of disseminated sclerosis and post-encephalitic parkinsonism seemed better after treatment, and in a child of 8 with chorea all move-

ment had ceased after the first of four treatments. The speaker considered that electropyræxia should be administered only by expert doctors and with the help of specially trained nurses.

Dr. E. WEISSENBURG (Vienna) agreed with the French workers that very weak doses could produce definite results.

Dr. SCHLIEPHAKE considered that some cases required weak doses, others strong. Both the case and the dose must be selected.

In the afternoon of May 13th at a meeting of the section of electrotherapy held with Dr. E. P. CUMBERBATCH in the chair, papers were read on the

#### Physical Aspects of Short-wave Therapy

Mr. B. S. GOSSLING (London) discussed some Physical Aspects of Ultra-short Wave Technique. After commenting briefly on essential differences of outlook between therapy and radio-engineering he surveyed those aspects of the apparatus which had most effect on the technique of operation. An ultra-short wave therapy apparatus could be divided into four parts: the oscillation generator, the coupling, the application system including the electrodes, and the patient. The purpose of the high-frequency generator was to liberate energy in the patient. A simple calculation showed that only a small proportion of the available energy reached the patient, and that if changing technique caused a large proportion to do so dangerous conditions might arise. A generator, for instance, might have an output of 200 watts. That represented approximately the production of heat at the rate of 3000 gramme calories per minute, or the rise of 1° F. per minute in 12 pounds. Such energy if spread over the body would cause a rise of 1° F. in about 10 minutes, or if liberated in local treatment in a small mass of tissue a rise of several degrees a minute. The connecting system usually consisted of more or less parallel wires. Unexpected effects might be produced in them in special circumstances. If the length of these wires was a quarter of a wave-length, if, for example, they were 3 to 5 feet and the wave-length 6 metres, they might constitute a powerful transformer. Then a certain current at a certain voltage might enter at one end and quite a different current at a different voltage come out at the other. This transformer action could only occur if there were a marked difference in conditions at the two ends, one end being electrically more open than the other. The adjustment which had to be made at the generator end to obtain resonance would always close or open that end in agreement with the opening or closing at the patient end. In this way the output might be automatically adjusted to the geometrical form of the tissue. Considered in electrical terms, a patient generally amounted to some 10 ohms of resistance. As the current usually passed through the tissues in the course of treatment was only a few amperes the voltage required to drive that current could not be more than 100 volts or so, and the field strength in the tissues only a few volts per centimetre. The application might be made by the condenser field or the coil field method. In the condenser field method the patient was separated from the electrode plates by one or two centimetres. At the 6-metre wave-length the voltage required to drive an ampere through a centimetre cube of air was 40,000 volts, four hundred times as much as a cubic centimetre of tissue needed. Only a small proportion of the voltage therefore was applied to the patient, and it could be used to best advantage if the air gap were

small, the resistance of the patient great, and small electrodes used. The action of the alternating magnetic field of the alternating current in the coil was to produce in the peripheral regions of the tissue a voltage which drove a current round in a ring. The current had not to cross the air gap and the voltage required was low. The greatest effects were obtained here if the resistance of the patient were as low as possible. The effect of the coil tended to be superficial, while with the condenser, though possibly less intense, it could be deeper. Mr. Gossling mentioned that a weak field acting on a low resistance produced an appreciable current; he was tempted to speculate whether a nerve, acting as the conductor, might have set up a rectified current within it. The passage of even a small continuous current along a nerve could have a very marked effect on its sensitivity.

Dr. KARL M. WALTHARD (Geneva) spoke about the Heat Generated by High-frequency Currents. In the course of short-wave treatments he had wanted to gauge the amount of energy transformed into heat in the body. He had carried out experiments in which he had put glass vessels of saline of different sizes and shapes between the electrodes of a short-wave apparatus. He had then ascertained the heat generated at various strengths of current. He had not been able to determine the distribution of heat within the vessels.

Prof. B. ORNSTEIN (Vienna) described a special apparatus for generating short waves.

Dr. H. J. TAYLOR (London) had tried to ascertain whether wave therapy of any particular length had any specific effect on mouse tumours. He had been unable to detect any change in the dielectric constant of the tissue at any wave-length. Necrosis might be induced in mouse tumours by ultra-short waves, but this could only be attributed to the heat generated. He had determined the minimum effective dose, and had found it to be ineffective if a cold blast of air were blown on the tissues during treatment; one-tenth of the effective dose repeated 100 times had no effect. The necrosis could be produced at various wave-lengths. He had never seen the changes in the tissue limited to the tumour only.

Mr. B. D. H. WATERS, M.Sc. (London), described the Thermionic Valve as a Generator of High-frequency Currents. He told how the thermionic valve had evolved since its invention by Fleming in 1904 to the triode used in wireless and for the generation of high-frequency currents.

Prof. F. H. HOPWOOD (London) commented that the effects of ultra-short waves on the heterogeneous systems of physiology differed profoundly from those obtained in a homogeneous medium in the laboratory. In life local effects might, perhaps by trigger action, lead to further chemical actions.

---

**NEW SUSSEX HOSPITAL FOR WOMEN AND CHILDREN, BRIGHTON.**—In her broadcast appeal made for this hospital recently, Miss Irene Vanbrugh stressed the need for more private wards, and money to pay off the debt incurred in the building of the new nurses' home. The home is to be opened by Lord Leconfield this week. Princess Louise Duchess of Argyll has consented to become president of the institution. No fewer than 822 patients were admitted last year; 722 X ray examinations were made; 8700 treatments were given in the massage and electro-therapeutical department; 2014 investigations were made in the pathological department; and out-patients numbered 4489. Nearly all these figures show an increase compared with 1934. The deficit has grown to £469 as compared with £291 despite every care.

### THE NEW SYSTEM OF HEALTH INSURANCE

LAST July I described a new system of sickness insurance which had lately been introduced in Austria. It was originally intended to come into force at the beginning of 1936, but as it was a complete revolution and as there was justifiable fear that a serious hitch might follow rapid adoption of the new principles, the authorities decided to wait another three months before completely destroying the old institutions. Thus the public, the medical profession, and the officials would find it possible to adapt themselves to the new situation, and to find out what was useful and practical and what measures should be discontinued. On taking stock of the new system last month, it was believed that certain of the innovations were working satisfactorily. A merger of three sickness insurance institutes, comprising the employees of the commercial, the industrial, and the financial companies and businesses, has been organised, called *Arbeitsgemeinschaft der Angestellten-Krankenkassen* (coöperative institute of employees' sick clubs). All the medical men previously employed in these individual *Krankenkassen*, either at a fixed salary or on a capitation basis, can now be consulted without restriction by all members, who can choose from the 258 general practitioners and 114 specialists the one they think suits them best. There are also 92 dental surgeons at their disposal, whom they can consult free of charge, and 244 other dentists to whom they have to pay a small fee. The Coöperative Institute pays all medical men and dentists a certain fee for each consultation or call. This is not a fixed amount; it varies according to the finances of the institute, for it has been agreed with the medical profession that a certain proportion (25–30 per cent.) of its income shall be set aside for medical aid. This includes all the expenditure on fees, for medical, obstetrical, and dental treatment, therapeutic appliances, medicines, and hospital accommodation, as well as on the pensions of doctors who previously belonged to the insurance societies and are not to work under the new arrangement. The dependants of the insured persons are also entitled to obtain medical aid, but they have to pay the chosen doctor part of the fee (about 40 per cent.); the other part is paid by the institute. At present a unit of about 1s. 4d. for the ordinary consultation and 2s. for a call at the patient's home is thought to be covered by the means at the disposal of the institute, the fees for specialists being about twice that sum. But it is clearly understood that at the end of the year a committee of representatives of the profession and of the institute will meet to consider the financial situation. This committee is entitled to reduce these fees if necessary; it may however increase them, if the money is available out of the 30 per cent. premiums paid by the members. In no case will public funds be called upon to make ends meet, as was the custom previously. In order to control the working of the new system, and to prevent abuse of any kind—e.g., too frequent calls, and too much or too expensive treatment—a controlling body of medical men and officials of the institute has been appointed. Thus it is hoped that the profession, although forced to accept the lowering of fees, will find the new arrangement not wholly disappointing, while the insured employees will be able to select the doctor they want, and obtain more personal treatment.

The arrangements with the *Arbeitsgemeinschaft* of the labourers are based on somewhat different principles. Here it has become necessary, owing to the large number of insured members and the variety of their homes, to organise a special plan of appointments of medical men. In each district a certain number of doctors will be selected to minister to the needs of the insured members in such a way that the work will be more evenly distributed among them. Not all practitioners, however, will be admitted to the list of appointments. It is understood that medical men already working under the insurance system, or in the Government insurance institutes, or in the municipal services, will not be eligible in this labourers' coöperative institute. But as the dependants are also entitled to medical aid—their number is calculated at about 75,000—quite a large number of practitioners will have to be appointed to that list. It is therefore expected that the new system will allow the authorities to enable the large majority of practitioners to make some sort of living out of the new arrangements, whereas hitherto only about 25 per cent. of the Vienna doctors were employed in the services of the *Krankenkassen*. The arrangements concerning the fees are nearly identical with those of the *Arbeitsgemeinschaft* of the town employees: 25–30 per cent. of the income from the premiums of the members will be devoted solely for medical aid as explained above. But the fees will be lower by about 30 per cent.—a unit of 1s. for the office consultation, 1s. 6d. for the call at the patient's home, and about double the fees for the specialists. Again, a financial committee will regulate the value of the unit of fees at the end of each year, with power to cut it down or to raise it as is required or possible, and a control committee will see that no untoward or too liberal use of the funds is made by the members or doctors. In order to limit the expenditure on drugs each physician will be free to prescribe only up to a certain sum for each patient. If his prescriptions exceed this limit, he will be asked to refund the excess to the *Krankenkasse*.

One of the chief advantages to the profession under this system is the arrangement that all associations, committees, and corporations are based on the principle of collaboration between the profession and the insurance body, each delegating to every committee an equal number of representatives. This is expected to ensure a smooth-working organisation for the benefit of all concerned. It is however a regrettable drawback that a number of doctors will have to remain outside the list of those eligible. The arrangements here sketched will apply not only to Vienna but to the whole of the Republic. In the provinces where the overcrowding by medical men is not so serious as in the capital, the prospects of a fairly satisfactory state of affairs are very hopeful, as far as the finances of the doctors are concerned. But in any case, the entire arrangements are regarded as tentative, with a view to testing them for a year or two, before they are made permanent by legislation.

#### FOUNDATION OF AN AUSTRIAN SOCIETY FOR MICRO-CHEMISTRY

A few days ago there was founded in Vienna a society for micro-chemistry, which is intended to act as an international centre for this new branch of science. Prof. Molisch, the physiologist and botanist, is the president, whilst Prof. Emich of Graz, the originator of modern micro-chemistry, acts as honorary

president. The chiefs of thirty institutes of chemistry and pharmacology all over Europe have been elected as members, amongst them Prof. Böttges (Germany), Dr. Feigl (Vienna), Prof. Komarowsky (Russia), Prof. Miolatti (Italy), and Prof. Nieuwenburg (Holland). A museum for micro-chemistry is also being organised in the Vienna Pharmacognostic Institute, and all industrial and chemical institutions and laboratories will be free to ask for gratuitous advice on micro-chemical problems. A collaboration between medical, technical, and industrial research workers and students is aimed at so as to promote the use of these important new methods in everyday problems.

### THE LEADERS OF FRENCH MEDICINE IN THE NINETEENTH CENTURY

THE theatre of Vieux-Colombier in Paris was filled the other day by an appreciative audience enjoying a lecture by Prof. Mauriac, of Bordeaux, on the influence on their time of the medical leaders of the nineteenth century. As far as the world of letters was concerned, he was inclined to think that the austere influence of great clinicians such as Laennec was much less than that of such fantastic figures as those cut by Mesmer, by Gall, the inventor of phrenology, and by Lavater, the creator of physiognomy. Such literary giants as Cabanis, Balzac, and Goethe were carried off their feet by the airy fancies of these three worthies, and Prof. Mauriac has come to the cynically dismal conclusion that the doctor who wishes to become influential and famous will do so with the greatest ease if he invades those ill-defined regions where the mysterious begins, and where medicine joins hands with faith and superstition. "In order to make a name, a more certain effect can be obtained by titillating the pituitary mucosa and by wielding a rod with dexterity than by practising orthodox medicine. Charlatans attract because there is something inexplicable about them." Prof. Mauriac's character sketches included Pasteur and Charcot. Pasteur seems to have been rather a dull dog. After dinner, when his pupils collected about him, he would take forty winks if the conversation turned on literature and politics, but he would wake up promptly when they discussed shop. "A one-book man, but how great a book!" Pasteur did, indeed, once put up for election to the Senate, but he was beaten by a politician; this was doubtless for the best, if not for the politician, at least for science. Claude Bernard and Grasset were influential only on account of their work, whereas Charcot scored most heavily by virtue of his personality. While he lived, the prestige he enjoyed was tremendous, but events have destroyed three-quarters of what he built; and hysteria, the disease he unknowingly created, has died with the last of his disciples. One of the points to which Prof. Mauriac returned more than once was the influence of medical pioneers on contemporary literature, the most recent example being Duhamel's indebtedness to Charles Nicolle.

### THE TRAFFIC IN MEDICAL PRACTICES

Dr. Paul Boudin, legal adviser to *Concours Médical*, has summarised in a recent issue of the journal, for the benefit of the younger generation of French doctors, the legal aspects of the traffic in medical

practices. The law adopts a none too sympathetic attitude towards it, refusing to accept the goodwill of a practice as a commercial commodity. In other words, the personal confidence a doctor enjoys in his practice cannot legally be assessed in terms of money. But this technical obstacle to the exchange of money for an exchange of practices can in practice largely be overcome by selling the lease of a house, equipment, &c., instead of the goodwill. The seller may also undertake not to practise any longer in the district in question; and when differences of opinion arise between the seller and the purchaser, it is customary to settle them by arbitration conducted by three colleagues, one chosen by each of the disputants, the third by the first two. The proceedings of the three are characterised more by common sense and an intimate knowledge of the conditions of medical practice than by any great learnedness of law. But it may happen that the dispute has ultimately to be settled by a properly constituted legal tribunal. In his advice to the participants in the negotiation of a practice, Dr. Boudin seems to credit the purchaser with more innocence and less perspicuity than the vendor. The purchaser must be particularly beware of him who shifts frequently from one practice to another, combing out and removing all the operable tonsils and appendices in a district, showing substantial returns for his operative activity, and then selling the newcomer the practice swept clean of these appurtenances. Another undesirable vendor is he who has left his practice for his practice's good, his professional shortcomings, his private life, or political or religious quarrels having constituted a very undesirable legacy for the newcomer. Dr. Boudin remarks that in his youth doctors were prepared to wait patiently till patients reposed confidence in them, and he adds that it is with reason that the law courts are inclined to look askance at disputes over the traffic in medical practices.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

### INSANITARY SCHOOLS IN COUNTY DUBLIN

GIVING evidence last week before the Local Government (Dublin) Tribunal, Dr. J. A. Harbison, medical officer of health for County Dublin, commented on the overcrowded and insanitary condition of certain school buildings in the county. He said that in 1934 he had reported three schools in the borough of Dun Laoghaire as being overcrowded, but nothing could be done in the matter. The floor space per pupil required in the Irish Free State was lower than that in most other countries. He thought that the total cost of building schools should be borne by the State. It was as much a function of national education as the provision of teachers. Bad school accommodation must be removed as part of the general scheme of preventive medicine. It is not only in County Dublin that insanitary school buildings are found. In the last published report of the Department of Local Government and Public Health it was stated that defects in sanitation were general in rural schools. It is not clear whether the responsibility for this state of affairs rests with the Department of Local Government and Public Health or with the Department of Education, but it is discreditable to both that it should be allowed to continue.

## MEDICINE AND THE LAW

### The Title of "Nurse"

REGISTERED medical practitioners naturally feel aggrieved when some impostor "wilfully and falsely" takes the title of "doctor of medicine" or "surgeon" or, in the words of Section 40 of the Medical Act, "any name, title, addition or description implying that he is registered under this Act." They can therefore sympathise with the registered nurses who have a similar ground of complaint when, as in a recent murder trial, someone is described as "Nurse Waddingham" whose name is not in fact upon the State Register. Newspaper reports of the coroner's proceedings upon the death of Miss Baguley indicated that Ronald Joseph Sullivan, who assisted "Nurse" Waddingham in conducting the "nursing-home," had the letters "S.R.N." printed after his name. Neither of the two was a registered nurse or a State certified midwife. A visiting-card is said to have shown the letters "S.R.N." and "S.C.M." after their respective names. Since doctors usually desire to use the services of registered nurses only, or at least to know when for some special reason they are employing an unregistered "nurse" it is disconcerting to find evidence of such impostures. How far is the doctor obliged to go in verifying the qualifications of nurses or midwives? A few years ago an impostor not only borrowed the name of a registered medical practitioner, but also stole his framed diploma and exhibited it to assist his fraudulent impersonation. The exhibition of a registered nurse's certificate upon the walls of a nursing-home might equally not be conclusive. The principle of professional registration must evidently be protected by vigilant and incessant action to expose fraud. This involves an elaborate organisation and considerable expense for prosecutions. Not all professions are equipped on the necessary scale. To return to the case of R. v. Waddingham, it was hardly possible during the trial to make any official statement to the effect that the accused was not entitled to the qualifications in question without prejudicing her prospect of a fair hearing. Any such statement made by leave of the judge at the conclusion of the proceedings is likely to obtain little publicity in comparison with the prisoner's previous identification with those qualifications.

### Juries as Judges of Insanity

English juries have to perform many difficult tasks and, in doing so, they must be unanimous. Otherwise the administration of justice breaks down. In a probate case tried last March (In the Estate of Wright, Lambert v. Woodham) the task was to decide whether a testatrix was or was not of sound mind at the time when she executed her will. Mental capacity is regarded as a question peculiarly suitable for decision by juries both in civil and in criminal cases. This particular jury, however, had found itself unable to attain unanimity. The members came back into court and confessed their failure. The judge then gave them a common-sense homily on the virtues of agreement. Here was an estate which had already been largely consumed by litigation. Disagreement would mean fresh litigation and fresh expense. The condition of the lady's mind was the sole issue; no moral principle was at stake. The court could not accept a majority verdict; the parties would not be satisfied with it. Do not feel too strongly, said the judge, about a matter

which is a question of degree, if you can fairly see that there is much to be said on the other side. It would be unfair to everybody if members of the jury did violence to their reasoned conviction; but they should "make a real broad-minded effort to see the other fellow's point of view." The jury tried again and reached a unanimous conclusion. The losing side thereupon appealed on the ground that the court had misdirected the jury by telling the minority to abandon its own judgment and to surrender to the majority. The Court of Appeal held that the judge had merely been admonishing the members against obstinacy: he had simply told them to try to pool their views and see whether they could not, by the ordinary process of discussion, arrive at a common conclusion. The Master of the Rolls thought the judge had gone rather near the line in some of his observations but had remained on the right side of it. The finding of the jury was not vitiated, and the appeal was dismissed with costs. Twelve laymen, not immediately unanimous, are thus the final authorities upon a question of insanity. Might not such issues be better left to a judge assisted by an expert assessor?

### POST-GRADUATE TEACHING OF PUBLIC HEALTH

THE Medical Act of 1886 required the General Medical Council to register such diplomas or degrees in public health as appeared to them to have been granted under suitable conditions of education and examination. In 1888 the Local Government Act made the possession of a *registered* diploma or degree in public health a condition of appointment in the case of medical officers of health of counties and of districts with a population of 50,000 or over. Accordingly the G.M.C. issued in 1889 their first set of Rules for the guidance of Licensing Bodies which desired to have such diplomas or degrees given recognition in the Medical Register. The first post-graduate course of training in public health had been instituted 19 years before these rules made their appearance. Trinity College, Dublin, led the way in 1870 and at the first examination held in 1871 Sir John Moore, recently chairman of the public health committee of the G.M.C., was one of the four successful candidates. It is hard to realise that the public health service of this country was brought into being and reached its present stage of development all within the professional lifetime of one who happily is still with us.

The rules of the G.M.C. have been revised at frequent intervals in order to keep pace with the rapid advances in preventive medicine and public health administration, and the hope that another revision would shortly be undertaken was expressed at a meeting on May 15th of the Society of Medical Officers of Health when the post-graduate teaching of public health was under discussion. It was pointed out that the course of training in public health had suffered in much the same way as had the ordinary medical curriculum; many new subjects had been added but no old subjects had been omitted. There was general agreement that, if the rules were simplified and some of the existing requirements modified, the course would be of greater educational value. Criticism was directed in particular against "Chemistry in relation to Public Health," mainly owing to the fact that practically all licensing bodies have interpreted this as meaning practical laboratory

work of the kind ordinarily undertaken by a public analyst. It is important that post-graduate students of public health should return for a time to the salutary discipline of the laboratory, but the two laboratory subjects to which their attention should in the main be directed must surely nowadays be bacteriology, together with immunology, and physiology in its application to problems of public health. Such chemistry as is included in the course should be taught first in relation to these two subjects and secondly with a view to enabling students to interpret intelligently the various analytical reports that may have to be dealt with administratively by the medical officer of health. Much of this teaching can be given in lecture-demonstrations and the student himself need practise only a very limited number of chemical laboratory exercises. There is, too, little to be said for the retention of practical chemistry in the examination for Part I. of the diploma in public health.

Various other suggestions were put forward at last week's meeting. One speaker entered a plea for the more practical study of statistics and for the separation of instruction in hospital administration from attendance on the clinical practice of a hospital for infectious diseases. Others advocated a return to the old system of apprenticeship to a medical officer of health as an essential part of the training of an entrant to the public health service. There seems to be a tendency in certain quarters to make the course for the D.P.H. almost entirely vocational in character. Important as it is for students to acquire the technique of public health administration, the aim of post-graduate teaching should rather be to provide them with a training in scientific method, to afford them opportunities of reading for themselves some of the literature of preventive medicine and, by discussion and demonstration, to develop their critical faculties. In such fashion medical men and women will acquire something which, added to their existing medical knowledge, should form a sound foundation upon which to build their subsequent public health practice. Some speakers pointed out the impossibility of providing a really adequate course of training on a part-time basis, while others expressed the opinion that numbers of students would be prevented from studying for the D.P.H. were whole-time attendance required at courses of instruction. At many teaching centres in this country whole-time and part-time students are working side by side and there are obvious difficulties in the way of providing both types of student with equally satisfactory training. Some clearer definition in the rules of the nature of the part-time attendance that should be permitted would not now be amiss.

Public health covers so vast a field of effort that no hard-and-fast system of training can possibly equip a man or woman for all the work undertaken by members of the public health service. Hence the rules governing the course of training and the examinations should never be too rigid. They should insist on certain essentials, but should be drafted in sufficiently wide terms to enable schools to develop freely along their own particular lines. There are advocates of the institution of subsidiary courses of training for those interested in such special branches as maternity and child welfare or school medical work. There is, however, much to be said for giving all those entering the public health service the same basic training and the same comprehensive outlook on preventive medicine. The desirability of providing short "refresher courses" dealing with recent

advances in clinical work and administrative practice is recognised. Certain courses of this kind are already available and doubtless others will be arranged from time to time. In any event, it is

important that the Society of Medical Officers of Health should give thought to the post-graduate teaching of public health in which so many of its members have played a prominent part.

## PUBLIC HEALTH

### SMALL-POX, MAJOR AND MINOR

#### THE RECENT TREND OF INCIDENCE AND FATALITY

PRECISELY when "variola minor" became in recent years epidemic in this country it is impossible to determine. It was certainly widespread in 1923 and there were indications of its presence in 1919 to 1922, or even earlier. In 1911-18 the notifications of small-pox were 906 and the deaths attributed to it numbered 80, a fatality of approximately 9 per cent. In 1919-34 the notifications reached the enormously high figure of 82,012, but the deaths were only 320, a fatality-rate of less than a half per cent. Even this low figure may overstate the real fatality since the rules of tabulation demand that many deaths certified to be due both to small-pox and another cause must be debited to small-pox. The epidemic reached its peak in 1927 and then slowly died out. In 1935 only 1 case of small-pox was recorded.

The situation is not, of course, unique to England. In recent years the prevailing strain has been of the non-virulent type in the United States, Canada, and South Africa. For instance, in the United States nearly 382,000 cases of small-pox were recorded in 35 States in 1921-30 with a case-fatality of only 0.9 per cent. On the other hand in India and other countries of the Far East the prevailing strain shows no change from the virulent type observed from ancient times, while in a few countries the non-virulent and the virulent strains exist side by side. Thus in some of the Southern States of America affected by the non-virulent type, with the low fatality referred to above, importation of the virulent type has taken place from Mexico and caused severe epidemics. This position has recently been discussed<sup>1</sup> by A. W. Hedrich, Sc.D., of the department of biostatistics in the School of Hygiene and Public Health of the Johns Hopkins University. He believes that the observed fatality-rates are not inconsistent with the view that there exist two principal strains of small-pox virus, the one a malignant form which produces fatality-rates distributed about an average of some 25 to 30 per cent. (an average which is perhaps unduly high), and the other a mild form with a fatality of less than 1 per cent., while if strains of intermediate fatality exist they have not succeeded in establishing themselves as successfully as have the very mild or very severe strains. Starting from this hypothesis he endeavours to explain the distribution of the types over the different countries of the world.

In very well vaccinated countries, such as those of continental Europe, Hedrich believes that the immunity of the population is raised to such a level that variola minor with a lower degree of infectivity than variola major is unable to maintain itself. The malignant form may still occasionally overcome the induced higher degree of immunity, so that the small-pox observed in such countries will be confined to the malignant type, with a low incidence rate but high fatality-rate. In very incompletely vaccinated countries, on the other hand, such as India, China, and Mexico (or in all countries in the pre-Jennerian days)

the population makes no effective attack upon either variety, with the result that variola major becomes the predominant type owing to its greater power of infectivity and diffusion. Finally, in such countries as England and the United States the appearance of variola major leads to the most vigorous efforts on the part of the highly organised health services, by means of isolation, control of contacts, and extensive vaccination and revaccination. Variola minor, on the other hand, is combated less vigorously. The problem of prevention is indeed much more difficult. As was pointed out in the report issued<sup>2</sup> by the Ministry of Health, unrecognised cases may be numerous, the identification or notification of cases may often be delayed till too late for effective action, vaccination is less readily accepted, and the difficulties of tracing contacts are substantially increased.

The result, Hedrich suggests, is that the dispersibility of the milder form is relatively high and it becomes the predominating type. The great discrimination between the attack made upon the major and minor varieties he illustrates by the experience of Detroit. In 1923 variola minor was epidemic but in spite of active propaganda the number of health department vaccinations averaged only about 6000 per month, mostly children. When shortly afterwards malignant small-pox was imported from Canada half a million persons were vaccinated within a month and about 70 per cent. of the entire population within five months. Hedrich admits that the predominance of variola minor in such areas as South Africa and the West Indies is difficult to reconcile with his thesis, but the information available is scanty and he leaves it to the future to determine whether "other causative factors" must be sought to explain this distribution. The course of the recent epidemic of variola minor in this country shows clearly that it is a type of infection which succeeds in attacking only a small proportion of the population, in spite of the difficulties of combating it and the apparent susceptibility of the population.

The remainder of Hedrich's study is devoted to a detailed consideration of small-pox in the United States. He finds, as has been seen in this country, that the vagrant migratory labourer has been influential in its spread. There are indications that the incidence has increased during times of prosperity through intensified migration to industrial centres from rural areas where, as a report<sup>3</sup> by S. D. Collins shows, the vaccination rates are relatively low and the attack rates somewhat higher than in the cities. Conversely during the recent industrial depression the incidence has declined, though the time sequence of an epidemic disease is, of course, notoriously difficult to interpret in relation to possibly correlated factors. Collins's study of the frequency of vaccinations and cases of small-pox shows that only a small proportion of the people of the United States, perhaps 10 per cent., are revaccinated at intervals of seven years or less, and the great majority of children vaccinated at entrance to school (when a large percentage of vaccinations appear to be carried out in the States) are never revaccinated. His survey shows that for persons above 15 years of age about 65 per cent. had been vaccinated and in addition 4-5 per cent. had been attacked by small-pox. Vaccination was more frequent in the highest and lowest income classes than in the intervening income group. Of the 17 cases of small-pox that occurred in the

<sup>1</sup> Public Health Reports, Washington, vol. li., No. 14 (April 3rd, 1936).

<sup>2</sup> Rep. on Pub. Health and Med. Subj., 1931, No. 62.  
<sup>3</sup> Public Health Reports, Washington, vol. li., No. 16, 1936.

surveyed population during the year 16 were among persons never vaccinated and only 1 among persons who had been vaccinated (in this one case forty years previously). The chief risk of variola major to the States comes, according to Hedrich, from Mexico and, in lesser degree, the Asiatic ports, if immigration, including smuggled labour from these sources, should be resumed with the return of more prosperous times.

### Small-pox in East Sussex

Among the Registrar-General's notifications of infectious diseases for the week ended May 2nd appeared two cases of small-pox in Brighton and one in Hove. We learn that the cases arose in this way. Mrs. A, who had been vaccinated and revaccinated—the last time in 1930, when it seems doubtful if it took—was returning from India and probably was infected at Port Said. She left the boat at Plymouth on April 1st, felt tired on the 5th, definitely unwell on the 6th, and on the 7th she had what she thought was an attack of malaria for which she took quinine. A doctor was called in on the 8th and prescribed further doses of quinine, which the patient took in more rapid sequence than was prescribed. By the 10th the temperature fell and spots appeared. The rash was considered suspicious of small-pox by the doctor but, as he had never seen a case of it himself, on April 13th he called in a consultant who diagnosed a quinine rash.

The first warning received by the local health authorities was when a nurse, who had been with Mrs. A on the 11th, 12th, and 13th, developed a rash on the 28th. On this occasion the doctor in attendance called in the medical officer of health for Hove. Small-pox was diagnosed and the case was removed to hospital on the 30th. The medical officer of health for Brighton then went to see Mrs. A, found numerous quite typical seeds in the soles of her feet, and learned that one of her maids was at her home ill. This illness was also found to be small-pox with onset on the 26th. Practitioners in Brighton and Hove were at once informed of the occurrence of small-pox and asked to notify any doubtful rashes. No further case of small-pox has been notified to date except the husband of the nurse who had been kept under observation and was removed on

suspicion at onset and before the development of the rash.

The vaccinal history of the four cases should be mentioned. Mrs. A, as already noted, had been vaccinated several times. The nurse had been vaccinated in infancy and revaccinated; she had a typical mild attack. The maid, aged 65, had been vaccinated in infancy; she had a typical severe attack and for a time was seriously ill. The nurse's husband had been vaccinated in infancy and at the age of 9; he developed only a few spots. Contacts were kept under close observation in the interval between the end of the incubation period and a fortnight after vaccination. All known contacts accepted vaccination. Further spread of small-pox is now improbable.

### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED  
MAY 9TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1996; diphtheria, 926; enteric fever, 27; pneumonia (primary or influenzal), 931; puerperal fever, 48; puerperal pyrexia, 110; cerebro-spinal fever, 30; acute poliomyelitis, 1; encephalitis lethargica, 6; dysentery, 16; ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 15th was 5812, which included: Scarlet fever, 1056; diphtheria, 809; measles, 2677; whooping-cough, 559; puerperal fever, 22 mothers (plus 15 babies); encephalitis lethargica, 283; poliomyelitis, 2. At St. Margaret's Hospital there were 26 babies (plus 12 mothers) with ophthalmia neonatorum.

*Deaths.*—In 122 great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 63 (28) from measles, 10 (3) from scarlet fever, 29 (7) from whooping-cough, 32 (4) from diphtheria, 56 (20) from diarrhoea and enteritis under two years, and 41 (5) from influenza. The figures in parentheses are those for London itself.

Measles is now definitely on the wane, the number of deaths for the last eight weeks (working backwards) being 63, 83, 104, 102, 103, 81, 104, 114, for the country as a whole, and 40, 70, 68, 60, 43, 62, 62 for Greater London. Deaths from diphtheria were reported from 19 great towns, 4 from Liverpool, 3 from West Bromwich. Rochdale reported the only death from typhoid outside London.

The number of stillbirths notified during the week was 299 (corresponding to a rate of 42 per 1000 total births), including 47 in London.

## PANEL AND CONTRACT PRACTICE

### Spinal Jackets Again

THE Ministry of Health have recently informed an insurance committee that the Minister's medical advisers regard the term "spinal jacket" used in the Medical Benefit Regulations as including appliances known in the trade as "spinal braces." Care should however be exercised in ordering on an insurance prescription either a jacket or a brace for it is not in every case that the appliance may properly be prescribed. The regulation says "when required for treatment of fractures, dislocations or diseases of the spine." An insurance doctor recently received a letter from a hospital almoner saying that an insured person had been examined by the surgeon and recommended a spinal brace. The almoner added, "As this appliance comes under Medical Benefit will you kindly arrange to apply for the brace on your National Health Insurance form. Miss X is suffering from pseudo coxalgia of the right hip." The doctor in all good faith issued a prescrip-

tion which the patient took to a local chemist. Fortunately for the doctor the chemist, before arranging for the supply of the appliance, consulted the insurance committee, who pointed out that the affection of the hip could hardly be described as a fracture, dislocation, or disease of the spine. If the chemist had supplied the article he would have been entitled to be paid for it and the insurance committee would have had to surcharge the doctor—some eight guineas!

The moral is that in case of doubt it is prudent to consult the insurance committee before issuing a prescription for an appliance. It may be noted that the Scottish Department of Health is advised that spinal jackets when used in the circumstances indicated above may be regarded as splints within the meaning of the Scottish Medical Benefit Regulations, which, unlike the English regulations, do not specifically provide for the ordering of spinal jackets. The appliance must, however, be prescribed by insurance practitioners in the course of treatment being given

under their Terms of Service. For example, an appliance may have been required not in the course of medical treatment but for aesthetic purposes, or by way of a mechanical aid after any treatment had ceased; or the appliance may have been required for the purpose of treatment which the insured person was receiving, not from his insurance practitioner, but from a specialist not under contract with the insurance committee. In such cases the appliance would not be held to be available under medical benefit.

### Still Silent

Some months ago we referred (1935, ii., 1206) to the case of Dr. A, against whom a complaint had been made, who neither replied to the inquiries of the insurance committee nor attended their hearing by the medical service subcommittee. We pointed out that possibly Dr. A had a perfectly good answer in reply to his alleged failure to provide treatment for an insured person but he would now be asked by the Ministry of Health to explain not only this but his attitude to the committee, and that he ran the risk of removal from the medical list. The inquiry committee appointed by the Minister heard the case on Jan. 1st, but Dr. A neither appeared nor was he represented; all that he did was to send a letter saying that he wished to dispute any complaint brought against him with regard to professional attendance. He admitted he had not replied to the complaint. After the hearing by the inquiry committee, a further letter was received from Dr. A bearing the date Dec. 30th, 1935, in which for the first time he communicated the line of his defence to the charges which had been made. Certain comments in that letter have received publicity in the lay press, particularly a statement that while he was acting as superintendent of a hospital Dr. A had had to protect

and guide some panel practitioners; there were, he added, many more in practice who might be quite good as nurses, but not as diagnosticians who would take responsibility for no case other than a cold or an ingrowing toenail. He treated human beings to the best of his knowledge which was wider than that of the average practitioner and, therefore, he resented mud being slung at him.

The inquiry committee found the charges made by the insurance committee to be proved or admitted, and submitted that the conduct of Dr. A in the case of the insured person regarding whom complaint was made appeared to be a breach of Art. 8 (1) of the terms of service and to constitute negligence within the meaning of Art. 41 (5) of the regulations. They stated that the letter from Dr. A did not affect the view of the case which was formed at the hearing. He had offered therein no satisfactory explanation why he failed to visit the insured person, or to make arrangements for the receipt of messages, or how he came to charge an insured person a fee or why he failed to attend before the inquiry committee. The Minister decided not to remove Dr. A's name from the medical list; he has been informed that it was with some hesitation that this conclusion had been reached, and that he must not expect a similar degree of leniency in the event of any further representation for his removal being made and substantiated. The sum of £10 is to be withheld from the insurance committee and must be deducted from the remuneration payable to Dr. A, who also has been required to pay £5 towards the costs of the inquiry. The sequel is worthy of record as an illustration of the extent to which, under the present administration of the Insurance Acts, justice has been tempered with mercy. But it seems a woeful waste of public time and money on Dr. A's part.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. J. W. Tighe placed on the Retd. List.  
Surg. Lt. C. Ommanney-Davis to rank of Surg. Lt.-Comdr.  
Surg. Lt. E. L. Littler to *Pembroke* for R.N.B. and to *President* for R.A.F. Medical Officers' course.  
Surg. Lt. (D) H. P. L. Rhodes to *Victory* for R.N.B.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdrs. T. C. Larkworthy to *Pembroke* for R.N.B.; and J. L. Cox to *St. Angelo* for R.N. Hospital, Malta.  
Surg. Lts. R. Cormack and M. Godwin promoted to Surg. Lt.-Comdrs.; and D. R. Goodfellow to *Victory* for R.N.B.  
Proby. Surg. Lt. D. R. Maitland to *Caledon* for training.  
Surg. Sub-Lts. R. A. Stenhouse (proby.) and P. H. K. Gray to *Victory* for R.N. Hospital, Haslar.

### ROYAL ARMY MEDICAL CORPS

Maj. E. H. W. Elkington retires receiving a gratuity.  
Short Service Commissions: Capt. F. Williams resigns his commission.

### ROYAL AIR FORCE

Squadron Leader G. S. Strachan to Special Duty List while in interchange duty with the Royal Australian Force.  
Flight Lt. S. B. S. Smith to R.A.F. Station, Biggin Hill.

The vacancy as consultant in medicine, Central Medical Establishment, which will be caused by the retirement of Group Capt. H. A. Treadgold, will be filled by the appointment of Wing Comdr. A. F. Rook with effect from May 18th. He was appointed to the R.A.F. General Hospital, Palestine, last year. (*Vide* THE LANCET, Nov. 30th, p. 1262.)

### INDIAN MEDICAL SERVICE

Lts. G. R. C. Palmer, J. Revans, and T. Sommerville are restd. to the estabtd.

To be Lts. (on prob.): A. C. Taylor, E. N. Brockway (secd.), L. S. F. Woodhead, J. G. Thompson, J. R. Kerr (secd.), L. M. Kelly, and K. I. E. Macleod.

The notification in the *Gazette* of May 1st, 1936, regarding Lt. S. C. Misra, is cancelled.

The undermentioned officers have vacated appts. in India: D.D.M.S.: Maj.-Gen. T. G. F. Paterson, C.B., D.S.O., K.H.P., I.M.S. (since ret'd.). A.D.M.S.: Col. W. T. McCowen, V.H.S., I.M.S. A.D.H. and P.: Maj. J. S. K. Boyd, R.A.M.C. A.D.P.: Lt.-Col. L. Dunbar, O.B.E., R.A.M.C. D.A.D.H.: Lt.-Col. J. G. Gill, D.S.O., O.B.E., M.C., R.A.M.C. D.A.D.P.: Lt.-Col. R. B. Price, D.S.O., R.A.M.C. M.O., A.Sch. of Education: Capt. G. B. W. Fisher, I.M.S.

The undermentioned appts. have been made in India: A.D.M.S.: Col. J. B. Grogan, Brit. Serv. A.D.H. and P.: Lt.-Col. J. G. Gill, D.S.O., O.B.E., M.C., R.A.M.C. A.D.P.: Lt.-Col. R. B. Price, D.S.O., R.A.M.C. D.A.D.H.: Lt.-Col. K. Comyn, R.A.M.C. D.A.D.P.: Maj. C. D. M. Buckley, M.C., R.A.M.C.

Embn. Med. Offr., Kiamari: Maj. J. McFadden, R.A.M.C., March 9th, 1935.

### COLONIAL MEDICAL SERVICE

The following appointments have been made: Medical Officers, West Africa: Dr. R. J. C. Campbell, Dr. J. W. Pickles, and Dr. A. B. Weir; Uganda: Dr. D. G. Snell; Northern Rhodesia: Dr. K. C. P. Thomson. District Medical Officer, Windward Islands: Dr. L. M. Commissiong. Dr. J. M. Mackay becomes Deputy-Director of Health Service, Gold Coast, and Dr. P. S. Selwyn-Clarke Deputy-Director of Health Service, Nigeria.

## OBITUARY

**JOHN SMITH FRASER, M.B.,  
F.R.C.S. Edin.**

THE death occurred on May 11th, at his home in Edinburgh, of Dr. J. S. Fraser, who for the past fifteen years had been a lecturer in diseases of the ear, nose, and throat in Edinburgh University, and surgeon to the Royal Infirmary of Edinburgh in the ear, nose, and throat department. Dr. Fraser, who was 61 years of age, was born in Fife, where his father, who later was appointed a Commissioner in Lunacy, was medical superintendent of the Fife District Asylum. His mother was a sister of the late Sir John Batty Tuke. He was educated at George

Watson's College and Fettes College, and studied medicine at Edinburgh University, where he graduated with first-class honours in 1897. As an undergraduate he obtained his "Blue" as a member of the university tennis team. He held resident posts in the Royal Infirmary, both on the medical and surgical sides, and spent five years as an assistant in general practice in Lichfield. He then decided to specialise in diseases of the ear, nose, and

DR. FRASER

[Photograph by Ayton

throat, and spent some time in the study of these subjects in London and Vienna. On his return to Edinburgh in 1905 he was appointed clinical assistant in the ear, nose, and throat department of the Royal Infirmary, under Dr. McKenzie Johnston and Dr. Logan Turner, and in that year passed the examination for the fellowship of the Royal College of Surgeons of Edinburgh. In 1906 he was appointed assistant surgeon in the ear, nose, and throat department of the Royal Infirmary, and in 1921 was appointed surgeon in the department, and lecturer in diseases of the ear, nose, and throat in the University of Edinburgh.

Dr. Fraser was a man of high intellectual range, and with an infinite capacity for hard work. To quote from the words, in *The Scotsman*, of a personal friend and colleague:

"The mere enumeration of Dr. Fraser's appointments conveys very little idea of what he actually accomplished in his professional career, or of the high position to which he attained in the speciality during thirty-five years of service on the honorary staff of the Royal Infirmary. He was a happy example of the man who combined, in a somewhat unusual degree, the intellectual gifts which made him both a successful clinician and an earnest scientific investigator. From the first he threw himself heart and soul into the work of the laboratory, and during the years of waiting for practice—and, indeed, to the end of his life—he worked indefatigably at the many problems which interested him. The pathology of diseases of the ear still offered a fruitful field, calling for exploration, and, having mastered the difficult technique required in the preparation of that organ, a necessary preliminary

for its microscopical investigation, he applied himself to conscientious and painstaking research. Of particular merit is his work on congenital deaf-mutism, on tuberculous disease of the ear, on the chronic form of deafness familiarly known as otosclerosis, and in the demonstration of the pathways of infection from the ear to the brain, and its covering membranes.

"He thus laid a sure foundation upon which he built his clinical experience, his accuracy in diagnosis, and his well-deserved reputation as a successful operating surgeon. He was a prolific writer; his papers always showed evidence of very careful preparation and of his power of exact observation. A popular teacher, he expressed himself in lucid and simple language so that there was never any doubt as to his meaning or to the essential points he desired to make. In debate he was often a forceful and candid critic, enlivening the discussions at scientific meetings when they were perhaps inclined to languish. . . .

"Although handicapped by indifferent health during the past two years, Dr. Fraser faced the future with characteristic courage, and continued his work to the end. A loyal friend and a helpful colleague, with whom it was always a pleasure to work, and most considerate of the feelings of his patients, Jack Fraser will be greatly missed by a large circle of friends and acquaintances."

Dr. Fraser's work received wide recognition, not only in this country but abroad. By the Royal College of Surgeons, Edinburgh, he was awarded, in 1922, the Liston Victoria Jubilee Prize, a quadrennial award for meritorious contributions to practical surgery; from the Royal College of Physicians, Edinburgh, in 1929, the Ireland-Barbour Fellowship; and in 1930 the Norman Gamble Research Prize of the Royal Society of Medicine, London. He was president of the otological section of the Royal Society of Medicine in 1927-28, and president of the oto-rhino-laryngological section of the British Medical Association in 1934, and was an honorary member of the American and Austrian Otological Societies and of the Oto-Rhino-Laryngological Society of Madrid. He was the author of numerous articles in text-books and the medical press.

Dr. Fraser is survived by his wife, a daughter of Major Reichsritter von Bouvard of Vienna, and by two sons, graduates with honours, one in science and one in medicine, of Edinburgh University, and by two daughters.

**FRANK MAINWARING HUGHES, M.D. Brux.,  
M.R.C.S. Eng.**

Dr. Frank Hughes, who died at Cambridge on May 14th at the age of 48, was born in Assam the son of Dr. A. D. Hughes and educated at the Leys School, Cambridge. He proceeded for his medical training to the London Hospital where he qualified in 1912 with the English double diploma. He then acted as house surgeon, house physician and resident anaesthetist at the Poplar Hospital, and was assistant surgeon at the Gravesend Hospital when military duties called him abroad with the rank of captain, R.A.M.C. He continued his military services after the war as senior medical officer to the Red Cross Hospital, Kent, and received the Legion of Honour. Always closely associated with ambulance work he was an examiner, official surgeon, and lecturer for the St. John Ambulance Association, of which he was an honorary life member, and he was decorated by the Société Française de Sauvetage and received also for humanitarian work a Belgian order. He held many appointments in the south of Kent, was medical officer of health for Walmer, on the staff of the Victoria Hospital, Deal, physician to the Deal Infectious Diseases Hospital, and medical

referee under the Ministry of Pensions for the Deal district. He recorded interesting clinical experiences in both *The Lancet* and the *British Medical Journal*. An early death cut short a very useful career.

**WILLIAM W. R. ASPLEN, M.B. Lond.**

Dr. William Reginald Ward Asplen, who died on May 14th at Kenilworth, received his medical training at the Westminster Hospital and qualified with the English double diploma in 1909, proceeding to the degree of M.B., B.S. Lond. in the following year. He acted as house physician and house surgeon to the Westminster Hospital and later as house surgeon to the Coventry and Warwickshire Hospital. He served during the war with a commission in the R.A.M.C. and then started in practice in Warwick. He established a good position both in a private capacity and as the holder of responsible official positions. He was deputy coroner for central Warwickshire, visiting medical officer to the Justices in Lunacy for the

county, surgeon to the police, honorary medical officer to the Kenilworth Convalescent Home, and chairman of the Kenilworth Ratepayers' Association. He was a valuable friend to the community.

**MUKHTAR AHMED ANSARI, M.B. Edin.**

THE death is reported from India of Dr. Mukhtar Ahmed Ansari, who was well known for his political activities as a vigorous leader of the national movement in India. He was educated at the Muir Central College, Allahabad, and the Nizam's College, Deccan, and obtained his medical degrees in Edinburgh in 1905. He was appointed house surgeon at Charing Cross Hospital and later became resident medical officer at the Lock Hospital. He organised the All-India Medical Mission in Turkey in 1912-13. On his return to India he was elected president of the All-India Muslim League. His sudden death occurred on May 10th in a train during a journey from Mussoorie to Delhi.

## PARLIAMENTARY INTELLIGENCE

### MIDWIVES BILL IN COMMITTEE

ON May 12th, 14th and 19th the Midwives Bill was considered by Standing Committee C. of the House of Commons.

#### Non-County Boroughs as Supervising Authorities

On Clause 1 (Provision of domiciliary service of midwives) Major HILLS moved an amendment to leave out the word "supervising" with a view to enabling certain of the non-county boroughs to exercise control of the midwifery services in their areas. He said that certain of the smaller boroughs were now supervising authorities under the Midwives Act and a further number of smaller boroughs were also in the same position under Section 62 of the Local Government Act, 1929. Under that section non-county boroughs and county districts were authorised to apply to the Minister of Health to make them a supervising authority under the Midwives Act. But not many such authorities had passed the test and some of the larger ones still stood outside. What was wanted in the country was a prompt service for the pregnant woman, near her home and among people whom she knew. In the country the county council might sit many miles away from a non-county borough. He thought that those non-county boroughs which had established a maternity and child welfare service, and which employed a whole-time medical officer of health, should have the power to administer the Act. Six non-county boroughs at present employed salaried midwives.

Sir FRANCIS FREMANTLE said that since the passing of the Local Government Act, 1929, a great deal had been done in establishing municipal hospitals and the midwives had to work with those hospitals. If the midwife was appointed by the larger authority that authority could make arrangements to relieve her in case of sickness and holidays and would be in a position to provide for pension schemes. Under a larger authority there would also be far greater facilities for moving midwives round in different areas. He believed that the preponderating weight of argument was in favour of this service being under the larger authorities.

Captain ELLISTON supported the amendment.

Sir KINGSLEY WOOD said he had approached this matter entirely from the point of view of establishing a good midwifery service in this country. It was perfectly true that the local supervising authority was defined under Section 8 of the Midwives Act, 1902. The proposal in the amendment would mean the inclusion of a number of the smaller local authorities. Those authorities had done good work in connexion with maternity and child welfare, and he was

confident that whatever decision was reached on this matter they would secure the coöperation of those authorities. The amendment would involve the inclusion of 17 non-county boroughs whose population did not exceed 25,000. He was advised that if these authorities were included it would only mean the employment at the most of two or three midwives. That meant in effect that unless they adopted the proposals in the Bill they would not get what was essential as far as it could be obtained—namely, an adequate choice of midwife by the women concerned. Another thing which they should aim at was the raising of the status of the midwifery profession as a whole. How could they do that if the country was divided up into a number of small authorities employing only two or three midwives? Such a system would not provide proper opportunities for promotion. He would, however, undertake to give sympathetic consideration to any applications made to him by smaller local authorities to be made supervising authorities for midwifery in their areas.

The amendment was negatived by 36 votes to 11.

#### Position of Voluntary Organisations

Mr. REYS DAVIES moved an amendment to exclude voluntary organisations from the Clause. He said that in order to achieve the purpose of reducing the rate of maternal mortality in this country they must raise the status of the midwife and make her a more efficient servant of the public. The Ministry of Health in all its reports had condemned the present condition of affairs in regard to the midwifery service. This Bill, however, continued in part the very thing which had been condemned—namely, the voluntary system.

Mr. BEAUMONT said that magnificent work was being done by voluntary organisations at the present time in this country. Whatever views might be held on the general principle he thought most people would agree that it would be a great pity to scrap the work of the voluntary agencies and start again afresh.

Miss RATHBONE thought that if it was a question of starting a new midwifery service there would be much to be said for putting that service entirely under the auspices of the local authorities. But here they had a service which had been carried on for a long period largely by voluntary organisations which had accumulated an immense body of practical experience.

Sir FRANCIS FREMANTLE said that in this Bill the Government were taking the voluntary organisations for what they were worth, seeing what were their good points and what were their deficiencies and their

introducing a scheme which would fill in the gaps. They should, he thought, use whatever services were at present doing good work; that was the policy of the Joint Council on Midwifery on whose report this Bill was founded. The Queen's Institute of District Nursing was the main centralisation of these voluntary organisations. The nurses engaged in it were either Queen's nurses—whose qualifications included three years' training in an approved hospital and the training necessary to qualify under the Central Midwives Board—or else village nurse midwives. In many country districts there was neither the work nor the funds to justify the engagement of Queen's nurses and yet there was a great deal of general nursing work for village nurse midwives, and a system of employing them had grown up by degrees not only in a voluntary way but in coöperation with the public authorities. The result had been coöperation with the public authorities for general nursing, midwifery, school nursing, tuberculosis nursing, attendance at maternity and child welfare centres and antenatal clinics, and last but not least the nursing of necessitous persons under grants from the public assistance committees. These nurses were helped not only by the money but by the active sympathy of those who formed the voluntary nursing organisations. During the period 1924 to 1933, 606,000 confinements were attended by Queen's nurses with an average maternal mortality of 1.91 per 1000, compared with one of 4.5 for the whole country. In England and Wales there were 3169 associations employing 2150 Queen's nurses and 2956 other nurses or a combined strength of over 5000 nurses. There was an expenditure of over £1,000,000 and the cost of a Queen's nurse to the organisations was £231 per year and of a nurse in the other category £184 per year. This was a splendid work and was recognised even in those areas which were poorest and most distressed. It was clear that these voluntary organisations should continue.

Mr. BATEY said that if it were merely a question of nursing a good deal could be said for the voluntary organisations, but there could be no argument against putting the work of midwives into the hands of the local authorities.

Mr. LECKIE said that in Staffordshire the branches of these local associations were largely supported by working people who would resent any interference with their work.

Mr. BURKE said it was true that there had been a great deal of valuable work done by voluntary organisations in the past, but the time had come when these organisations would have to go by the board.

Mr. FRANKEL said it was only because the Government and the local authorities had not faced up to their duty that voluntary organisations had had to do some of the work. This Bill proved that there were many local authorities which possessed nearly all the powers contained in this Bill, but had not exercised them. It was not fair to compare the maternal mortality-rate of 1.91 per 1000 for confinements attended by Queen's nurses with the rate of 4.5 for the whole country, because voluntary organisations could pick and choose their cases. The cases that had little chance of survival went into the public municipal hospitals where the bulk of the poor people were being looked after. There ought to be no overlapping of control in regard to midwives.

Sir KINGSLEY WOOD said he believed that these voluntary organisations were part of the genius of the British people. He saw no prospect of voluntary effort ever failing in this country. He had designed this Bill, in conjunction with those who had helped him, with the object of enabling the voluntary organisations to participate in the work under the Bill to the fullest possible extent. He had also inserted a clause by which that work would be operated as part of the municipal service. He wanted to get the best from both sections. It should be pointed out that although for a considerable

time local authorities had been able to appoint midwives only 64 midwives had been so appointed up to that moment by the whole of the local authorities. The great burden of this work of midwifery so far as the rural districts of the country were concerned had been carried out by the great voluntary organisations. It was not a fact that their nurses picked and chose the cases. In a village where one of the Queen's nurses was a midwife she went to any case where assistance was wanted unless the mother desired to call in a doctor. The case for this Bill was largely based on the high standard of maternal care which had been attained by the voluntary organisations which employed salaried midwives at the present time.

The amendment was negatived by 28 votes to 14.

#### Period of the Midwife's Attendance

Mr. G. GRIFFITHS moved an amendment providing that the period of attendance by the midwife should be 15 days instead of 10 as proposed in the Bill, and by permission of the chairman another amendment in the name of Captain ELLISTON proposing that the period should be 14 days was discussed at the same time. Mr. Griffiths said that all the women's organisations in the country were asking for this amendment. Captain ELLISTON said the period of 14 days was suggested in the report of the Departmental Committee on the training and employment of midwives, and endorsed in the interim and final reports of the Committee on Maternal Mortality.

Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, said that the reason why the period of 10 days had been inserted in the Bill was because that was the period of attendance by the midwife qua midwife prescribed in the rules of the Central Midwives Board. In the Bill they went further however and insisted that local authorities should see that even where a doctor attended a maternity case the mother should have the chance of being nursed by a properly qualified woman. Therefore it was prescribed that the same period of nursing—namely, 10 days—should apply as had been applied by the C.M.B. when the woman attended solely as a midwife. Medical opinion was growing to the effect that it would be beneficial if this period could be extended. Since the second reading of the Bill the Ministry of Health had had a letter from the C.M.B. to the effect that it was their intention to extend the period for the attendance of a midwife qua midwife to at least 14 days. If the amendments were withdrawn the Government would put down before the report stage an amendment to the effect that the period of attendance of a woman as a maternity nurse should correspond to the period that should from time to time be laid down by the C.M.B. as the period for the attendance of a woman qua midwife.

In view of Mr. Shakespeare's statement Mr. Griffiths and Captain Elliston withdrew their amendments.

An amendment providing that arrangements should only be made with voluntary organisations in areas in which such organisations were already providing an approved service of salaried midwives was also defeated.

#### Midwives' Salaries

Mr. E. DUNN moved an amendment to secure that the salary of midwives employed under the Bill should in no case be less than that of health visitors employed by the authority or working in the same area. He said that the midwifery service was a matter of national importance, and it was right that the women who took part in that service should be paid reasonable salaries.

Captain ELLISTON and Miss RATHBONE also had amendments on the paper dealing with the same matter. Captain Elliston said that he hoped the Minister of Health would see that the Bill was amended in such a way as to ensure those safeguards for the proper remuneration of midwives which he indicated in his speech on the second reading. Miss Rathbone said there was nothing whatever in the Bill as it

stood which really guaranteed the salaries which would be paid to midwives, especially those employed by voluntary organisations. They had a responsibility to see that the midwifery profession was no longer sweated as it had been in the past.

Sir KINGSLEY WOOD said that in England and Wales about 60 per cent. of confinements were attended by midwives, 20 per cent. by doctors, and 20 per cent. were treated in hospitals. It was certainly the object of the Bill to improve the status and remuneration of midwives, and he believed that those objects would be secured. Any suggestion that the local authorities should not be free to fix the salaries and remuneration of their officers would be rightly resented under our democratic local government system. So far as the voluntary organisations were concerned the terms of remuneration to be paid to the midwives appointed by them would be the subject of discussion and agreement between the voluntary organisations and the local authorities in order to secure uniformity and in consideration of the further financial assistance which was to be given to the voluntary bodies under the Bill. After the Bill had been passed he proposed to send a circular to the local authorities stating that in the view of the Minister it would be well if the local authorities regarded the status of midwives as very much akin to that of health visitors, and recommending that the salaries paid to midwives should be approximately the same as that paid to health visitors, and that the authorities should secure on their negotiations with the voluntary organisations that the latter should follow the same course. He thought that the committee could be assured that under the scheme he had indicated the views of hon. Members in this matter would be met.

#### NOTES ON CURRENT TOPICS

IN the House of Lords on May 19th Lord GAINFORD presented the Public Health (Drainage of Trade Premises) Bill, to amend the law with respect to the discharge of trade effluents into the sewers of local authorities.

The Bill was read a first time.

#### Vivisection Petition

IN the House of Commons on May 14th Mr. GROVES presented a petition signed by 175,000 petitioners praying that the House would make illegal the present practice of vivisection.

#### Medical Research and Workmen's Compensation

The introduction of direct control by constituting an ad hoc body to be known as the Workmen's Compensation Board was a feature of the Workmen's Compensation Bill in the House of Commons on May 15th. In moving its second reading Mr. G. HARDIE said that its main object was to take the whole business of workmen's insurance outside the range of competitive insurance companies, to prevent profit making in such a service, and to prevent money intended for the injured being wasted over legal quibbles. The proposed Board, with employers and employees represented upon it, would, Mr. Hardie believed, bring a much more human atmosphere into the consideration of claims.

After some debate, from which it emerged that many who were dissatisfied with the present law of workmen's compensation had even less confidence in the new proposals, Mr. LLOYD, Under-Secretary, Home Office, said that though the objections to giving this Bill a second reading seemed to the Government to be overwhelming, his desire to improve the workmen's compensation system was extremely sympathetic. It was desirable to try to get closer coördination between the health services and workmen's compensation schemes in order to secure what all parties wanted, irrespective of compensation, that the workman should recover and be able to get back to work as soon as possible, though not before he was fully

fit for it. It was clear from the British Medical Association report on Fractures that up-to-date technical methods were being applied in particular cases, but not all over the country as they might be. He believed that special clinics at Norwich, at Bristol, and Birmingham had extended very rapidly and had treated 2000 cases by up-to-date methods in the last year. The re-education of the injured limb for instance was of vital importance. Mr. Lloyd quoted the case of a senior medical inspector of factories who had recently broken his ankle; when the joint was restored to a completely satisfactory state from the medical point of view he found the utmost difficulty in walking, though he knew perfectly well that he could walk. If that happened to a medical man it was much more likely to happen to the average layman, and particularly the injured workman. It was therefore of the utmost importance that methods of re-educating injured limbs should be available. The Home Office was also alive to other new branches of knowledge, notably those which took note of the psychological dangers resulting from accidents. The Home Secretary had set up a committee containing trade union members, employers, and a number of progressive doctors who had practical experience of these matters and had made a special study of them, such as Prof. Hey Groves and Mr. Henry Souttar "to inquire into the arrangements at present in operation with a view to the restoration of the working capacity of persons injured by accidents and to report as to what improvements or developments are desirable, and what steps are expedient to give effect thereto, regard being had to the recommendations made in the report issued by the British Medical Association in February, 1935, on 'Fractures'." The Home Office hoped that a workable scheme might be produced by this committee, on which they might take action. The proper course of the House of Commons was not to pass this Bill but to await the reports of these committees and then to consider what workmanlike improvements they could make in what was already a very fine system of workmen's compensation.

Mr. PALING said he wanted to see doctors placed in a rather better position than some of them were in at present. Some of them were what was called "compensation" doctors. He (Mr. Paling) had recently had a case before him of a man who had had the front of his skull fractured and he had to go to the "compensation" doctor. He had previously been told, what he already knew, that his eyesight was deteriorating as a result of the injury. The "compensation" doctor said: "Oh, now there is a strike on at your post and you will want to keep on the fund and you have developed bad eyesight." The doctor admitted afterwards that it was his job to get men back to work. That was not a desirable state of affairs.

The motion for the second reading of the Bill was negatived by 167 votes to 111.

#### HOUSE OF COMMONS

THURSDAY, MAY 14TH

#### Food for Expectant Mothers in Special Areas

Miss WARD asked the Minister of Labour to which towns the special grant supplied by the commissioner for the supplying of special foods for expectant mothers had been allocated; and on what basis the selection was made. —Lieut.-Colonel MUIRHEAD, Parliamentary Secretary to the Ministry of Labour, replied: I am informed that the Commissioner for the Special Areas (England and Wales) has recently decided to make a grant of £3000 to the National Birthday Trust Fund, to enable them to extend their scheme for the distribution of special foodstuffs to expectant mothers; and with that assistance, I understand that the Fund have agreed to operate the scheme in the county boroughs of Gateshead, Merthyr Tydfil, South Shields, and Sunderland, and the Special Areas of Monmouthshire. The selection was made in consultation with the National Birthday Trust Fund, having regard

to the facilities available and the extent of arrangements already made.

Miss WARD: If these experiments are successful from the point of view of helping the mothers will the scheme be extended to other towns?

Lieut.-Colonel MUIRHEAD: I think that it has always been an understood thing that the operations of the Commissioner in the Special Areas are experimental, and no limit has ever been laid down as to what will be done if the experiments are successful.

#### Unemployment Assistance and Needs of Invalids

Mr. GRAHAM WHITE asked the Minister of Labour whether it was the practice of the Unemployment Assistance Board to take into account the special needs of invalids and others requiring additional nourishment when assessing household needs, or whether such requirements were held to be medical needs.—Lieut.-Colonel MUIRHEAD replied: I am informed by the Board that wherever it is ascertained that persons whom the Board is assisting are in need of extra food, such need is taken into account by its officers in deciding the amount of the allowances to be granted. This provision does not cover drugs or surgical appliances, which are definitely medical needs and therefore outside the scope of the Board.

#### Defence of Civil Population against Air Raids

Mr. SHORT asked the Home Secretary what progress was being made with local authorities respecting the defence of the civil population in case of air raids; how many authorities had been approached; and how many had agreed to cooperate.—Mr. GEOFFREY LLOYD, Under-Secretary, Home Office, replied: Local authorities are now actively engaged in preparing schemes of air raid precautions. All local authorities were asked to cooperate with the Government in this matter and all but a very few are doing so. Progress is very satisfactory.

Mr. SANDYS: Is my hon. friend now in a position to tell us what progress is being made in providing instruction for medical practitioners in giving first aid in gas cases?

Mr. LLOYD: Yes, Sir, but I should require notice of that question.

Mr. SHINWELL asked the Home Secretary the number of gas masks it was intended to purchase for the use of the civilian population; how many were already available; the names of the gases with which these protective devices had been tested; whether the local authorities were in possession of all necessary information in respect of the precautions which might require to be taken in the event of an air raid in which gases were used; and whether the gas masks were all of British manufacture.—Mr. GEOFFREY LLOYD replied: As was explained in answer to a question on April 8th last, the final design of the respirator intended for use by the civil population has not yet been settled. The number of respirators to be made will depend on a variety of circumstances, but, in any event, it is not anticipated that less than 30,000,000 will be produced. The respirator is designed to give protection against any probable concentration of any type of poison gas which might be met in time of war, but it would not be in the public interest to state the names of the gases against which it is being tested. Local authorities have received a certain amount of information on the precautions which are required against poison gas, and further memoranda on the subject are in course of preparation and will be available shortly. In regard to the last part of the question, any respirators made for the Government, or approved by them, will be of British manufacture.

TUESDAY, MAY 19TH

#### Nursery Schools in Slum Areas

Mr. LYONS asked the President of the Board of Education what development had been made within the last year in the provision of nursery schools in areas cleared of slums or about to be so cleared.—Mr. OLIVER STANLEY replied: Nursery schools are as a rule provided in areas where the housing conditions are unsatisfactory. Ten such schools have been recognised during the last year. The Board have also recognised some nursery schools on housing estates for persons formerly resident in slum

areas. Two schools of this type have been recognised during the last year, and the provision of others has been approved in principle.

#### CHILD GUIDANCE

A MEETING to demonstrate its work and methods was held by the East London Child Guidance Clinic last Monday under the chairmanship of Dr. C. S. Myers, F.R.S. Lady Cynthia Colville pointed out that only those skilled in the working of the mental processes are able to discover the roots of delinquency, and spoke of child guidance as one of the greatest liberating forces in social work. Mr. J. J. Mallon, LL.D., referred to the grave figures of juvenile delinquency; 26 per cent. of those taken into custody for indictable offences in 1935 were under seventeen years of age, and the peak in cases of larceny was at thirteen. Most of these young offenders were not lost causes; they were simply children who needed help. One young boy, referred to a clinic as a persistent thief, was found to be suffering from an endocrine deficiency. He stole merely to satisfy his craving for sugar, and medical treatment led to his reform. We were apt to envisage two states—health and not health—but actually there were many intermediate conditions. Excellent as the school medical service was, it was concerned almost entirely with the physical element; one great value of a clinic of this kind was that it called the attention of the nation to a defect in our educational apparatus. Many human beings were marred by failure to receive the kind of treatment provided by a child guidance clinic.

Dr. Emanuel Miller said the clinic brought the workers into touch with every sort of home and many types of educational and social organisation, and a very large amount of valuable information was being collected. But they had to do something to cure the children. Sometimes this depended on manipulation of the environment either of home or school. The clinic had to consider the individual peculiarities of the child—his mentality, his imaginative life. In this connexion play often revealed a great deal about the child's efforts to get equal with the world. Not infrequently a child who was regarded as a public nuisance by parents, teachers, and the police, became a very pleasant child and a favourite at the clinic.

Illustrative cases were described by members of the staff, and demonstrations of psychological testing, of play therapy methods, and of children's drawings used for purposes of diagnosis were given. Dr. R. N. Salaman, president of the Jewish Health Organisation, spoke of the nine years' work which the clinic had carried on. It needed to be placed on a wider basis and to find more suitable premises. The chairman said that 60 per cent. of the patients treated at the clinic were non-Jewish, and the time had come for more general recognition and support by the whole community.

**NEW HOSPITAL FOR GORLESTON.**—The buildings of the Grange Club at Gorleston are to be converted into a new hospital for the town. A sum of £4500 is needed to open it free of debt next October.

**HIRE PURCHASE SCHEME FOR MOTOR-CARS.**—The Medical Insurance Agency already arranges insurance protection under such headings as pension, life, endowment, household, and children's education, and the Doctor's Special Motor Policy will be well known to our readers. The Doctors' Motor Finance Ltd., in connexion with the Agency, has now arranged to provide hire-purchase terms for motor-cars, and Messrs. Mann, Egerton and Co. will act as consulting motor engineers. Full information and terms can be obtained from the secretary, the Doctors' Motor Finance Ltd., Tavistock House (North), Tavistock-square, W.C.1.

## CORRESPONDENCE

## BLOOD COUNTS IN TUBERCULOSIS

To the Editor of THE LANCET

SIR,—Dr. Heaf calls attention to the variability of reports on blood counts. I suppose that no hæmatologist will deny that different observers examining the same blood film may obtain different results: even the same observer may not get identical results from the same films in successive examinations. Dr. Heaf's fourth table shows that closely comparable results may be obtained by different observers using the same film. Surely, the constancy of the result must depend upon several factors, of which by far the most important is the number of cells counted. If only some 300 cells are examined (as I imagine was the case in Dr. Heaf's series), the discrepancies will be considerable. Examination of 500 cells for the differential count decreases the apparent variation a great deal. And, if 1000 cells are passed under review, there is very little discrepancy.

It is, of course, obvious that the differential count suffers from being performed on a random sample of blood; and only a portion of the random sample is examined. Differences in results are decreased if all films are examined serially in the same direction—e.g., vertically. And films made on cover-glasses give far less divergent results than those made on slides. I feel sure that, if the films sent to 11 competent authorities by Dr. Heaf had been prepared on cover-glasses, the results in his first three tables would not be so different. With cover-glass films it is necessary to do half the differential count on the one and half on the other film. In this way a fair sample of a *whole* drop of blood is examined; whereas, when films are made on slides, it is impossible to ascertain the nature of the cells that remain adherent to the spreader. It is only when the total number of leucocytes is moderately low that a differential count of 500 or 1000 cells will give consistent results.

It would seem that Dr. Heaf's observations are an indirect support of the view that leucocyte examination should be more qualitative in the sense of Arneth or Schilling. Properly trained observers will get almost identical results in estimating the Arneth index, especially with Cooke's modification of the original method. It would be a great pity if Dr. Heaf's letter undermined the clinician's interest in blood counts, but it will be excellent if it calls his attention to the value of the much neglected "qualitative" blood picture.

I am, Sir, yours faithfully,

Park Square West, N.W., May 15th.

A. PINEY.

## (?) EPIDEMIC MYALGIA IN MANCHESTER

To the Editor of THE LANCET

SIR,—At present there seems to be an outbreak of the so-called Bornholm disease (epidemic myalgia) in Manchester. In my practice, which is not a large one, I have latterly been seeing steadily one new case a day. The condition appears to be confined to adults; so far as this outbreak is concerned, at any rate. The onset is sudden, with an initial fever up to 100.4° F., which does not recur. The patients have an air of being extremely ill, and they can hardly drag themselves about owing to the shortness of breath that comes on with exertion; even walking on the level provokes profuse sweating. Night sweats occur and the pain is so severe and so

constant that the patients get no rest day or night except under the influence of sedatives. One patient, indeed, compared her pains to "the tortures of the damned." Relatively rapid wasting of the muscle groups affected (deltoid, trapezius and rhomboids, intercostals, muscles of upper arm, &c.) occurs, but it is too early yet to say how the wasted muscles will respond on recovery.

The foregoing description is suggestive of textbook accounts of trichinelliasis, from which it differs in the important particular that these pains may be localised to one particular muscle group, more often than not unilaterally. Multiple cases in the same house are occurring—husband and wife, employer and servant-girl—while two consecutively encountered cases were in adjacent streets.

Salicylates seem useless either to cut short the disease or to ease the pain. Local massage is of slight temporary benefit, but the patients (who are irritable and difficult to manage) soon abandon it because its effect is so transient. Symptomatic treatment, with rest in bed, seems the best that can be done.

I am, Sir, yours faithfully,

W. J. RUTHERFURD.

Manchester, May 19th.

## MENTAL SICKNESS AND CERTIFICATION

To the Editor of THE LANCET

SIR,—While in agreement with the suggestion contained in Dr. Dillon's letter in THE LANCET of May 16th, I should like to correct the impression which he, and possibly some of your other readers, may have gained with regard to the Institute of Medical Psychology. The hostel which we hope will be built in the near future is only designed to accommodate *psychoneurotic* patients who are ambulant. The ultimate extension on the site which the Institute has acquired, while it will contain beds, is still only intended for the treatment of the psychoneuroses. In London, at any rate, there would appear to be adequate facilities already provided for the treatment of psychotic patients.

I am, Sir, yours faithfully,

J. R. REES.

Institute of Medical Psychology, Malet-place, W.C., May 16th.

## FELLOWSHIPS IN CHILD GUIDANCE

DR. D. R. MACCALMAN writes to call further attention to three fellowships offered by the Child Guidance Council and advertised in our issues of May 2nd and 9th. They are tenable at the London Child Guidance Clinic, and their object is to give training in the medico-psychological problems of childhood. "The number of child guidance clinics," he says, "is steadily growing, and there is, in consequence, an increased demand for skilled personnel. This is especially true since the Board of Education agreed to allow these clinics to rank equally for grant with other school medical services, and local education committees have become interested in having such a service. It has been suggested that local authorities who are contemplating the establishment of a clinic might find it possible to second, for the purpose of taking a fellowship, any physician in their service who has the necessary background of psychiatric knowledge. The closing date for applications has been given as May 22nd, but applications of the above nature will receive consideration if sent in before May 30th."

## MEDICAL NEWS

### University of Cambridge

On May 15th the degree of M.B. was conferred on J. P. S. Peck.

### Royal College of Surgeons of England

At a meeting of the council held on May 14th, with Sir Cuthbert Wallace, the president, in the chair, a letter was received from the trustees of the Bernhard Baron Trust offering to give £25,000 for the erection of new research laboratories at the College in Lincoln's Inn Fields. The trustees said that they were impressed with the importance and value of the work now being carried out under very difficult conditions, and felt sure that with improved accommodation results would be achieved of the greatest value in the prevention and treatment of disease. A resolution was adopted expressing the best thanks of the council for this generous gift. The new laboratories will be named after the late Mr. Bernhard Baron.

Diplomas of fellowship were granted to William John Lawrence Francois (Glasgow and London) and to Frederick Gordon Kergin (Toronto). Diplomas of membership were granted to those whose names were published in THE LANCET of May 9th, p. 1095, as having received the licence of the Royal College of Physicians, and diplomas in tropical medicine and hygiene and in anaesthetics were granted jointly with the Royal College of Physicians to those who were mentioned on the same page.

Mr. H. S. Souttar and Mr. E. Pearce Gould were elected members of the court of examiners. Mr. G. C. Knight, F.R.C.S., was reappointed a Leverhulme scholar, and Mr. William D'Auvergne Maycock, M.R.C.S., was appointed a Leverhulme scholar. The honorary gold medal of the College was awarded to Dr. James Alexander Murray, F.R.S., in appreciation of his services as director of the laboratories of the Imperial Cancer Research Fund. It was reported that Mr. R. B. Wade, president of the Royal Australasian College of Surgeons, had accepted the honorary fellowship of the College. He will come to London for his admission at some future date.

The president was appointed ex officio a member of the governing body of the British Postgraduate Medical School for one year. The council considered a comprehensive report from a committee on the preliminary examination in general education and decided to make no change in the present regulations for this examination. The following hospitals were approved, with the posts specified, for the six months' surgical practice required of candidates for the final fellowship examination:—

Llandough Hospital, Cardiff.—Senior Resident Surgical Officer, Junior Resident Medical Officer (to July 31st, 1938).

Royal Infirmary and Dispensary, Doncaster.—Senior Resident with charge of Casualties, House Surgeon to Unit 3, House Surgeon to Unit 2.

Smithdown-road Hospital, Liverpool.—Resident Surgical Officer.

The council accepted with great pleasure Lord Moynihan's offer to present to the College the portrait of himself by Mr. Richard Jack, R.A.

### University of Glasgow

Sir Hector Hetherington, vice-chancellor of the University of Liverpool, has been appointed principal of the University of Glasgow in succession to Sir Robert Rait who retires on Sept. 30th. Before he took up his present post in Liverpool in 1927 Sir Hector held the chair of moral philosophy in the University of Glasgow.

### University of Aberdeen

At a meeting of the university court last week, the Royal Commission was presented, announcing that Dr. W. Hamilton Fyfe, principal and vice-chancellor of Queen's University, Kingston, Ontario, has been appointed principal and vice-chancellor of the university. A legacy amounting to £2000 has been received to provide a prize to the student showing the greatest proficiency in biology. Another legacy also amounting to £2000 is to be used to present prizes to the duxes of the year in medicine and surgery respectively.

### Royal College of Surgeons of Edinburgh

At a recent meeting of the College, with Mr. Henry Wade, president, in the chair, the following were admitted to the Fellowship:—

Robert Emmett Mullarky, M.D. California; Cyril Ferdinand Hecker, M.R.C.S. Eng.; Keshav Sokarji Jayakar, M.D. Bombay; Edward Henry Connell Shepherd, M.B. Edin.; Thomas Victor Stubbs Brown, M.B. Sydney; Richard Osmond Burrell, M.D. Manitoba; Eric Noel Callum, M.R.C.S. Eng.; Brennan Scott Cran, M.D. Aberd.; Robert Hugh Dewar, L.R.C.P. Edin.; Clifford Robert Eugene Downing, M.B. Edin.; Robert Allan Elliott, M.B. Edin.; John Burke Ewing, M.D. Kingston; Mahmud Hafezi, M.R.C.S. Eng.; Albertus Wynand Louw, M.B. Edin.; Graham Macpherson, M.B. Edin.; Arthur Harold Morley, M.B. Leeds; George Brown Morton, M.B. Glasg.; and Arthur Manus Sheridan, M.B. Glasg.

The following candidates received the higher dental diploma:—

A. J. W. Day, F. E. Gillieron, Andrew Muir, G. E. Firth, T. L. Winn, and G. B. Ashworth.

### Glasgow University Club, London

Owing to Mr. Ramsay MacDonald's indisposition, the annual summer dinner of this club has been postponed until Friday, June 26th. It will be held at 7.30 p.m. at the Trocadero Restaurant, Shaftesbury-avenue, W., and the hon. secretaries may be addressed at 62, Harley House, N.W.1.

### University of London Medical Graduates' Society

At the annual meeting of this society on May 12th Dr. Dorothy Hare was elected president, Mr. Philip H. Mitchiner hon. treasurer, Dr. Louise Livingstone and Mr. J. P. Hosford hon. secretaries, and Mr. Victor Bonney hon. secretary for overseas members.

### St. John's Skin Hospital, London

This hospital held its annual meeting for the first time at the new premises in Lisle-street, Leicester-square, on May 14th, when Captain Eric Smith appealed for assistance in clearing off the debt at the bank.

### Royal Bucks Hospital, Aylesbury

The Duchess of York has promised to open the new special departments building of this hospital and the extension to the nurses' home in the autumn. The committee has to raise £50,000 for this purpose, and so far over £22,000 has been received.

### Royal Sanitary Institute

The Bostock Hill memorial shield, which is offered annually by this institute for the best celebration of health week in the Empire outside the British Isles, has been awarded for 1935 to Rangoon for the health week and exhibition held there last year, which was organised by the Burma branch of the Indian Red Cross Society. The health week in Lagos, Nigeria, was highly commended, and those of Pretoria, Transvaal, and Port of Spain, Trinidad were commended.

### National Temperance Hospital, London

It is proposed to build a maternity and gynaecological wing on a site adjoining this hospital, and King Edward's Hospital Fund have allocated £2500 to the cost of building and £500 towards purchasing the site. The wing when erected is expected to be self-supporting, but £100,000 is needed for the cost of the site, equipment, and provision of 91 beds. The hospital still has a debt of £26,000, although last year income exceeded expenditure by £4689.

### Medical Telephone Exchange

The Johannesburg branch of the South African Medical Association has appointed a committee to investigate the possibility of organising a central telephone office for doctors. The doctor will notify a central bureau of his movements for the day and the bureau will find him for patients who ring up. It will no longer be necessary to search for a doctor by a series of telephone calls. If a quarter of the city's 400 doctors agree to become subscribers to the exchange it is thought that the scheme will be feasible.

**King Edward's Hospital Fund for London**

The King has appointed the Duke of York president of this fund.

A series of visits has once again been arranged for those who wish to help the Fund and to see London. On Wednesday, May 27th, Hampton Court Palace and the Old Court House, formerly the residence of Sir Christopher Wren, will be shown to the party, while on June 10th visitors will be able to go by private omnibus from Charing Cross to the Air Port of London. On June 17th one of the directors of Messrs. J. Lyons will show them round Cadby Hall, and on July 3rd a visit will be paid to Windsor Castle and St. George's Chapel. Tickets, either for the whole series or singly, may be had from the secretary of the Fund, 10, Old Jewry, E.C.

**Health Scheme at Wallsend**

The Board of Education and the Ministry of Health are prepared to give favourable consideration to a proposal by the Wallsend town council to build a new maternity home, child welfare centre, and school clinic, and the council has decided to acquire a site and proceed with the undertaking.

**Public Schools Exploring Society**

Applications are invited for one or two honorary physicians or surgeons to accompany this society's expedition to Northern Lapland from August 5th to Sept. 20th. Further information may be had from Surg.-Commander Murray Levick, White Barn, Old Oxted, Surrey, who will lead the expedition.

**South London Hospital for Women**

Two new operating theatres and two new wards were recently opened here as part of an extension scheme which will cost £45,000, and will include new general and maternity wards and an enlarged pathological laboratory. At the opening a cheque for £1000 was presented to the hospital from former patients.

**St. George's Hospital**

A donation of £10,000 has been made to the rebuilding fund of this hospital by Smith's Potato Crisps (1929), Ltd., as a token of loyalty to the memory of King George, with a suggestion that it should be used to found an industrial health research laboratory. The hospital authorities propose to include a laboratory, which will bear the name of the firm, in the new building to be erected at Hyde Park Corner.

**Fellowship of Medicine and Post-Graduate Medical Association**

Courses to be given during June are as follows: gynaecology at the Chelsea Hospital for Women (all day, from June 8th to 20th); M.R.C.P. course in neurology and psychotherapy at the West End Hospital for Nervous Diseases (afternoons, from June 8th to July 4th); clinical and pathological M.R.C.P. course at the National Temperance Hospital (8 p.m. on Tuesdays and Thursdays from June 9th to 25th); M.R.C.P. course in chest and heart diseases at the Victoria Park Hospital (Wednesdays and Fridays at 6 p.m. from June 17th to July 10th); and an M.R.C.P. course in chest diseases at the Brompton Hospital (two afternoons weekly from June 15th to July 11th at 5 p.m.). The following week-end courses will be given during June and July: general medicine at the Prince of Wales's Hospital (June 6th and 7th); obstetrics at the City of London Maternity Hospital (June 13th and 14th); fevers at the Park Hospital (June 20th and 21st); general surgery at the Prince of Wales's Hospital (June 27th and 28th); children's diseases at the Princess Elizabeth of York Hospital (July 4th and 5th); and heart and lung diseases at the Victoria Park Hospital (July 11th and 12th). On Thursday, June 11th, at 8.30 p.m., at the Royal Society of Medicine, Dr. Roland T. de Hollebranth, of New Jersey, U.S.A., will lecture on the present-day treatment in the United States of gastric and duodenal ulcers. All members of the medical profession are invited to attend. Further information may be had from the secretary of the fellowship, 1, Wimpole-street, W.1.

**North-West Durham**

The Lanchester rural council is recommending to the Lanchester joint hospital board the erection of a central hospital to serve the needs of north-west Durham and to replace the existing four hospitals at Tanfield, Langley Park, Lanchester, and Leadgate.

**St. Ann's Hospital, Nottingham**

Sir Hubert Bond, senior commissioner of the Board of Control, has opened this hospital, which is an extension of the Nottingham City Mental Hospital. It is to be used as an admission hospital for women and has cost £66,000.

**Industrial Health Education Society**

Lord Luke, presiding on May 13th at the annual general meeting of this society, recalled the fact that the disability of workmen from sickness or accidents accounts for an annual loss to the country of 28,000,000 weeks' work. The aim of the society was, he said, so to educate the workman that by his cooperation this loss might be reduced. The general secretary, Mr. J. Mackenzie, reported that during the past year 418 lectures had been given to workers by members of the medical profession. This had been done at small cost as the district trade-unions provided the place of meeting and defrayed the cost of advertising and other charges. The adoption of the report was moved by Sir William Haldane, one of the founders of the society. The Minister of Health, Sir Kingsley Wood, welcomed the cooperation of the medical profession and the worker. Ignorance, he said, was one of the worst foes to good health. Over and above the financial loss through accidents and sickness among workmen, there was the fact that the worker was deprived of a fuller and happier life. Mr. George Hicks, M.P., general secretary of the Amalgamated Union of Building Trade Workers, said that educational work of this kind was desperately needed. Only those closely in touch with the everyday life of the working man could know the ill-effects of bad housing, insanitary conditions, poor food, and unemployment on his health and work. Thanks to the speakers were voiced by Dr. G. Clark Trotter, hon. secretary of the society.

**Births, Marriages, and Deaths****BIRTHS**

**BUTTAR.**—On May 13th, at Salisbury, the wife of Dr. F. L. Buttar, of a daughter.  
**CROFT.**—On May 7th, the wife of Dr. C. R. Croft, Devonport, of a son.  
**LIGHT.**—On May 13th, at St. Thomas's Hospital, the wife of Dr. L. H. B. Light, of Burnham-on-Crouch, of a son.  
**REUVID.**—On May 10th, the wife of Dr. L. Reuvid, of Lewisham Park, S.E., of a son.  
**WATSON.**—On May 14th, to Dr. Grace Mizen, the wife of H. Watson, of Chingford, E.—a son.

**MARRIAGES**

**FINLAYSON—ROBOTTOM.**—On May 11th, at St. Paul's Church, Durban, Victor Alexander Finlayson, M.C. recently of Kingswood, Surrey, to Phyllis Muriel Robottom, M.B. Lond., younger daughter of Mr. H. C. Robottom, of Harlow Common, Essex.  
**GORMAN—YOUNG.**—On May 9th, at the Parish Church, Erdington, Everard Noel Griffin Gorman, M.B. Birm., of Hove, to Muriel Winifred Young, B.A., only daughter of Mr. Thomas Young, of Erdington.  
**MACEWAN—CHALLONER.**—On May 9th, at the Church of St. Giles, Dundonald, Alastair Birkmyre MacEwan, B.A., M.R.C.S. Eng., to Aileen Strang, younger daughter of the late Mr. and Mrs. R. C. Challoner, Barassie, Ayrshire.

**DEATHS**

**ASPLEN.**—On May 14th, at Kenilworth, William Reginald Ward Asplen, M.B. Lond., aged 50.  
**CARR.**—On May 12th, at Walford, Mary Brice Carr, L.R.C.P. and S. Edin., of Liverpool, second daughter of the late Robert Carr, of West Ditchburn, Northumberland.  
**EMERSON.**—On May 12th, at Falmouth, Peter Henry Emerson, M.B. Camb., in his 80th year.  
**FAULL.**—On May 13th, at Elms-road, London, S.W., suddenly, William Collins Faull, F.R.C.S. Eng., of Durban, South Africa, in his 48th year.  
**HUGHES.**—On May 14th, at Cambridge (the residence of his friend, Dr. Rogers), Frank Mainwaring Hughes (late of Walmer), M.D. Brux., M.R.C.S. Eng.  
**McFEELY.**—On May 14th, at Woolton, Liverpool, Joseph Daniel McFeely, F.R.C.S.I., D.P.H., in his 84th year.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Vaughan: 11. Preparations from Sternal Marrow Biopsies. 12. A Case of Agranulocytosis in which Pyramidon was Demonstrated in the Urine.

WEDNESDAY.

**Comparative Medicine.** 5 P.M. Annual General Meeting. E. J. Pullinger: Influence of Tuberculosis upon the Development of *Br. abortus* Infections in the Guinea-pig. H. P. Bayon: The Treatment of Yellow Anemia in the Fowl by Means of Liver Extracts. J. P. Lockhart-Mummery: Evolution and Disease. Lantern slides will be shown.

THURSDAY.

**Urology.** 8.30 P.M. Annual General Meeting. Dr. S. Zuckerman: The Endocrine Control of the Prostate.

### BRITISH PSYCHOLOGICAL SOCIETY.

Medical Section.

WEDNESDAY, May 27th.—8.30 P.M. (1, Wimpole-street, W.). Prof. C. G. Seligman: Patterns of Culture. Dr. Audrey Richards and Prof. J. C. Flugel will also speak.

### MEDICO-LEGAL SOCIETY.

THURSDAY, May 28th.—8.30 P.M. (Manson House, 26, Portland-place, W.). Mr. Albert Crew: Proof of Identity of Persons in Criminal Cases in its Medico-legal Aspects.

### ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, Lisle-street, W.C.

WEDNESDAY, May 27th.—4.15 P.M., Annual General Meeting and Clinical Cases.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

### ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, May 26th.—5 P.M., Sir Bernard Spilsbury: Doctrine of Inflammation. (Last Croonian Lecture.)

### UNIVERSITY OF LONDON.

THURSDAY, May 28th.—5.15 P.M. (University College Hospital Medical School), Prof. Charles Singer: Recent Light on the History of some Tropical Diseases.

### EAST LONDON CHILD GUIDANCE CLINIC.

WEDNESDAY, May 27th.—3 P.M. (Jews' Free School, Bell-lane, Bishopsgate, E.1), Dr. Alfred Adler: Demonstration Clinic on Cases of Child Neurosis and Behaviour Disorder.

### HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.

WEDNESDAY, May 27th.—2 P.M., Mr. A. Simpson-Smith: Appendicitis: Acute and Chronic. 3 P.M., Dr. Alan Moncrieff: Significance of Blood Passed per Rectum. Out-patient Clinics daily at 10 A.M. and ward visits at 2 P.M.

### BRITISH POSTGRADUATE MEDICAL SCHOOL, Duane-road, W.

MONDAY, May 25th.—2.15 P.M., Dr. Duncan White: Radiological Demonstration. 3.30 P.M., Prof. W. Fletcher Shaw: Genital Prolapse.

TUESDAY.—2 P.M., Prof. Kettle, F.R.S.: Pathological demonstration. 3 P.M., Dr. Janet Vaughan: The Differential Red Cell Count.

WEDNESDAY.—Noon, clinical and pathological conference (medical). 2.30 P.M., clinical and pathological conference (surgical).

THURSDAY.—2.15 P.M., Dr. Chassar Moir: Operative Obstetrics. 2.30 P.M., Sir Henry Gauvain: Surgical Tuberculosis. 3 P.M., Dr. R. A. Young: Non-tuberculous Pulmonary Diseases.

FRIDAY.—2.15 P.M., Dr. A. A. Davis: Gynaecological Pathology.

Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetrical and gynaecological clinics or operations.

### FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, May 25th, to SATURDAY, May 30th.—ST. JOHN'S HOSPITAL, Lisle-street, Leicester-square, W.C. Afternoon course in dermatology (open to non-members).—MAUDSLEY HOSPITAL, Denmark-hill, S.E. Afternoon course in psychological medicine.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. All-day advanced course in urology.—GORDON HOSPITAL, Vauxhall Bridge-road, S.W. All-day course in proctology.—LONDON LOCK HOSPITAL, Dean-street, W. All-day course in venereal diseases (open to non-members).—Courses are open only to members except where otherwise stated.

### HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.

THURSDAY, May 28th.—3 P.M., Dr. Blake Pritchard: Demonstration.

### LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.

MONDAY, May 25th.—5 P.M., Dr. H. MacCormac: Treatment of Syphilis.

TUESDAY.—5 P.M., Dr. H. W. Barber: Psoriasis.

THURSDAY.—5 P.M., Dr. A. M. H. Gray: Scleroderma and Allied Conditions.

FRIDAY.—5 P.M., Dr. R. T. Brain: Physiotherapy.

### INSTITUTE OF HYGIENE.

TUESDAY, May 26th, to SATURDAY.—Joint Congress with the Royal Institute of Public Health at Edinburgh.

### UNIVERSITY OF BIRMINGHAM.

TUESDAY, May 26th.—3.30 P.M. (General Hospital), Mr. H. H. Sampson: Demonstration of Clinical Cases.

THURSDAY.—4 P.M. (Medical Faculty Buildings), Prof. W. W. C. Topley, F.R.S.: Other Mechanisms of Immunity. (William Withering Lecture.)

FRIDAY.—3.30 P.M. (Children's Hospital), Mr. E. B. Alabaster: The Treatment of Concomitant Squint.

### ANCOATS HOSPITAL, Manchester.

THURSDAY, May 28th.—4.15 P.M., Dr. W. J. S. Reid: Psychopathology.

### GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, May 27th.—4.15 P.M. (Eye Infirmary), Dr. Pendleton White: The Significance of a Hard Eyeball.

### MANCHESTER ROYAL INFIRMARY.

TUESDAY, May 26th.—4.15 P.M., Mr. Geoffrey Jefferson: Observations on the Surgery of the Gall-bladder.

FRIDAY.—4.15 P.M., Mr. F. G. Wrigley: Demonstration of Ear and Throat Cases.

## Appointments

CURRIE, D. W., Ch.M., M.D. Leeds, F.R.C.S. Eng., has been appointed Hon. Obstetric Surgeon to the Leeds Maternity Hospital, and Hon. Gynaecological Surgeon to the Hospital for Women, Leeds.

ELLIS, R. W. B., M.D. Camb., M.R.C.P. Lond., Assistant Physician to the Children's Department of Guy's Hospital.

GILL, T. P., M.B. Aberd., F.R.C.S. Edin., D.L.O., Aural Surgeon for the Kent Education Committee.

HOLMES, E., M.B. Leeds, F.R.C.S. Eng., M.C.O.G., Hon. Obstetrician and Gynaecologist to the Royal Lancaster Infirmary.

MCGARRITY, K., M.B. Sydney, Obstetrical Registrar at the Southend-on-Sea General Hospital.

PALMER, H. A., M.B. Manch., M.R.C.P. Lond., D.P.M., Senior Assistant Physician at the Woodside Hospital, London.

SHARPE, D. A., M.B. Lond., F.R.C.S. Eng., Assistant Obstetrician to the Elizabeth Garrett Anderson Hospital.

WILES, PHILIP, M.S. Lond., F.R.C.S. Eng., Visiting Orthopaedic Surgeon at the West Middlesex County Hospital.

Certifying Surgeons under the Factory and Workshop Acts: Dr. J. C. G. WHITELAW (Bruton District, Somerset);

Dr. A. W. B. WIGGINS (Hoyland Nether District, Yorks, W.R.); Dr. B. H. GILSBANK (Knottingley District, Yorks, W.R.); Dr. R. JACKSON (Nelson District, Lancs);

Dr. A. J. SHEDDEN (Stirling District, Stirling); and Dr. R. C. HEWITT (Walton-on-the-Naze District, Essex).

A VISIT TO BATH.—Last week-end the history of medicine section of the Royal Society of Medicine held a meeting in Bath, which was also attended by members of the International Congress of Physical Medicine. During the afternoon the members were conducted over the pump room and Roman baths, and the treatment establishment, where methods of treatment by the thermal mineral waters were demonstrated. Later, there was a short tour of the historic parts of Bath, in the course of which Sir D'Arcy Power unveiled a mural tablet at No. 12, South Parade, to the memory of John Hunter, who stayed at this house in 1785. At dinner in the Guildhall the Mayor welcomed the guests and Dr. E. W. Goodall, president of the section, and Prof. Louis de Pap, of Budapest, responded. The guests then returned to the pump room, where Dr. F. G. Thomson gave an address on some early physicians of Bath, and the times in which they lived. On Sunday, after a short expedition by motor in the afternoon, the Mayor and Mayoress, Dr. and Mrs. J. S. Carpenter, entertained the party to tea.

## NOTES, COMMENTS, AND ABSTRACTS

## FAMILY MEDICAL INSURANCE

It is a comforting thought that in the midst of political upheaval and international anxieties well-intentioned people throughout the world are studying intensively problems of human welfare. The type of social endeavour which has developed since the war is exemplified in the attempts being made to improve the medical services of this and other nations. The stimulus for these efforts is provided by the disturbing conviction, which no serious student of the subject can escape, that only a minority of people in this country, or for that matter in any other, receives the full benefit of modern medical science. Most people are agreed on at least one other point: that while considerable reorientation of both medical practice and medical education may be necessary, or soon become necessary, the principal need at present is for a better organisation of the available services. It is on the method of achieving this that divergence appears. The latest recruit to the ranks of benevolent realists who not only recognise defects in the present system but are prepared to outline a scheme for their removal is Dr. John Lachlan-Cope.

In a foreword to a small book entitled "Family Medical Insurance: a New Scheme with Evidence," he explains that following the advice of various people to whom he had propounded his scheme in typescript, he has had it printed in order to elicit discussion. An introduction explains the standpoint from which the author starts; there follows a chapter entitled Evidence, which contains a series of statements and quotations in support of the extension and completion of health services on a contributory system without limitations or restrictions, the general practitioner remaining the hub of medicine. The crucial chapter, embodying a scheme whereby this is to be effected, will disappoint those who seek not quotations from Charles Kingsley and others, but a brief and clear outline of what is proposed. The seven points which purport to embody the main features of the scheme are specific in certain immaterial details, but vague in what seem to be essentials for its comprehension. It appears that while complete medical, surgical, maternity, and all auxiliary services shall be available to all without restriction or limitation, the final acceptance of membership and its *continuance* (our italics) shall rest with the Board of Governors and there shall be no appeal against their decision. The Family Medical Insurance would have clinics where patients would be examined and advised on production of letters from their family doctors, who would also receive reports of the findings at the occasional examination held for preventive purposes. Prescriptions, whether from clinic or family doctor, would be dispensed at special fees at the clinics, but "in F.M.I. institutions for *in-patients* no charge would be made for medicaments. Domiciliary treatment or consultations can be arranged when the family doctor considers such to be absolutely necessary or when circumstances render any other course impracticable" (p. 48). These vast services would be for premiums—a sliding scale based on income. The final point made is that the F.M.I. scheme would relieve the voluntary hospitals' financial situation but it is not until seven pages further on (p. 55) that a hint is given in what way this is to be achieved. Here it is suggested that every clinic besides being attached to the F.M.I. central institution, which will contain the medical record department, is also to be attached to various local institutions, including general and special hospitals, cottage hospitals, and nursing homes, the cooperation services of these institutions being remunerated by an annual grant based on local membership. The final chapter deals with medical education and nursing and it is proposed that at the central institution mentioned above post-graduate studies and research facilities should be available.

Apparently in Dr. Lachlan-Cope's view the principal need is the provision of a large number of specialist diagnostic and treatment clinics to which the middle-class subscribers or members for whom the scheme is devised would have free access, there to obtain the type of specialist service from which the poor and the rich are assumed to derive such great benefit in hospitals and in the consulting-rooms of leading advisers. It is, of course, universally conceded that the days when the family doctor could provide almost all necessary medical advice and treatment are gone for ever, and that his good offices must frequently be supplemented by specialist and ancillary service. The danger which many people would foresee in meeting this need through such a system of clinics as is proposed is that their service would become a substitute for rather than a supplement to that of the family doctor, thereby accentuating the modern tendency to uncoordinated and disintegrated specialism. It is true that the scheme provides that, except in the case of emergency, a letter of introduction from the doctor will be required before examination is made and treatment given, but it also proposes, in the interests of prevention, to encourage members to present themselves for periodical examination, not to their own doctors but at the clinic, and in this case a doctor's note will not be required. There can be little doubt that under arrangements of this kind the population would very soon become "clinic-conscious" if we may coin a word from the advertisement vocabulary. The general practitioner would come to be considered, as indeed he already is by some, merely as a stepping-stone to the clinic, a sort of middleman whose services are tolerated only because of their value in emergency. The clinic would almost inevitably become in the eyes of the patient the primary source of medical help and guidance, and thus the basis of medical organisation. Such an organisation is in fact already favoured in many places and by many people, and is developing in the United States and to an even greater extent in Soviet Russia whose legislators have deliberately adopted it. A sentimental attachment to the centuries-old British tradition of the family doctor would not prevent us from giving consideration to this plan if it were likely to be in the best interests of patients. But it is a matter of general agreement in this country that, as the interim report of the Scottish Consultative Council on Medical and Allied Services puts it: "The first essential for the proper and efficient treatment of individual persons is, therefore, not institutional but personal service, such as can be rendered to the people in their own homes only by a family doctor who has the continuous care of their health; to whom they will naturally turn for advice and help in all matters pertaining thereto; who will afford them such professional services as he can render personally; and who will make it his duty to see that they obtain full advantage of all the further auxiliary services that may be otherwise provided."

It may well be, of course, that the divergence of opinion is not so great as it seems; there are two points at any rate on which Dr. Lachlan-Cope and his readers will agree—that the terms and conditions of any insurance service must be acceptable to those operating it and the administration must be efficient and enlightened if it is to be effective. Especially those who see (and deplore) a tendency at the present time towards a national or State service, based on the clinic system and administered by local government authorities, should take note of any published schemes for a voluntary service and express a considered opinion on them. Anyone who submits a scheme that provokes discussion among the profession on the future of medicine in this country does a public service.

ROYAL SOCIETY OF MEDICINE.—The house and library of this society will be closed from Saturday, May 30th, to Monday, June 1st, inclusively.

### NATIONAL BABY WEEK

THE first week in July has been allocated by the National Baby Week Council for a campaign to cultivate public opinion on certain hygienic matters. This year special attention is to be given to (a) maternal welfare, stressing the constructive aspects—welfare and happiness—as distinct from maternal mortality, disease, and morbidity; (b) the welfare of the two to five year old, whether all is being done for them that should be done, nationally and locally. The Council, whose address is 117, Piccadilly, London, W.1, offers advice and help in the organisation of propaganda and the choice of subjects for lectures and articles.

### THE EAST END HOSTELS ASSOCIATION

THE annual report of the John Benn Hostel and Milner Hall for 1935 should appeal to medical men, so obvious is it that the care of the health, physical, moral, and mental, that is offered by the institution must greatly benefit the children that come under such ministrations. The disastrous influence of unemployment on the young is patent to us all, and juvenile delinquency is to-day a feature in police courts. It is therefore very satisfactory to read of the success which the superintendent of the homes has met with in finding good employment for many of the boys. The warden wishes to induce employers to visit the institution, evidently believing that information so derived may lead to an extension of mutual advantages. The institution is very accessible, standing off the Commercial-road, E., quite near the Aldgate metropolitan and district stations.

### GUIDANCE FOR MOTHERS

THE public, especially perhaps that of the United States, grows yearly more nervous about its physical and mental health and that of its young. This fear leads among other things to a demand for books advising parents how to bring up their children. One which has recently appeared<sup>1</sup> is a collection of articles published originally in the *Parents' Magazine* of New York. More than a hundred medical and non-medical writers have contributed to it. Many of the articles are short and sketchy, so sketchy indeed as to bring alarm rather than reassurance to an anxious mother. The effort to maintain the standard of information at a level which will be intelligible to all has resulted in a tendency to make it too simple to be helpful. To suggest, for example, that calcium deficiency alone is a frequent cause of faulty posture in adolescents is to simplify that problem unduly. Many will think, too, that the danger of competitive games is needlessly stressed. Those with subjective or objective experience may doubt whether boys are likely either to overstrain themselves or hurt each other very seriously by playing football. The psychological outlook of the child is sympathetically outlined in various articles. Prenuptial chastity is advocated for both sexes and a warning to young people of the dangers of venereal disease is recommended. The mother who turns to this book will certainly find therein something about the matter that is worrying her. The question is whether she will find enough to allay her fears or merely that little knowledge which will drive her, perhaps needlessly, to the doctor for reassurance.

### "QUIET"

THE Anti-Noise League, now two years old, has come to the conclusion that if you want quiet you must make a noise about it. With the object of spreading information and propaganda about noise prevention, the League has started a magazine called *Quiet*, to be published quarterly at sixpence by the League from 66, Victoria-street, London, S.W.1. The first issue, which has just appeared, includes a message from the Minister of Health, a foreword by Lord Horder, and a note on some medical aspects of noise by Sir James Purves-Stewart. Mr. E. V. Lucas

<sup>1</sup>The Mother's Encyclopædia. By Various Authors. British edition. Edited by Len Chaloner. London: George Allen and Unwin Ltd. 1936. Pp. 692. 8s. 6d.

quotes some pleas for anti-noise from Shakespeare, and there are unsigned articles on scientific research on noise abatement and on quietening London's underground. Wing-Commander T. R. Cave-Browne-Cave writes on aircraft noise, Mr. J. K. Winsor on quieter wall-cutting, Mr. R. B. Serle on measurement of loudness, and Mr. Raymond Savage on possible individual action to prevent noise. *Quiet* is in touch with anti-noise organisations abroad, and hopes to publish messages and reports from these at intervals. Laudable as are all these efforts at noise abatement, we still think that more might be done by the individual towards acquiring the knack of turning the deaf ear. No doubt some are more naturally adept than others in this matter, but a measure of callousness to extraneous sounds can be cultivated by all where necessity demands it, as many newspaper reporters and novelists could testify.

### A GALAXY OF CENTENARIANS

IN Hungary we are told the nonagenarians have been called into consultation in an effort to discover the causes of longevity. Dr. Jean Perrigault collects centenarians and scours his native France in search of authentic specimens (*Siècle Méd.*, May 1st). So far he has collected 66, of whom 56 are women and only 10 men, a striking testimony to the fact that the female of the species is not only more deadly, but also more lively, than the male. A composite picture of 15 centenarians, 11 women and 4 men, illustrates his article, and it is no mere gallantry to say that they all look younger than their years. Among the ladies, Mme. Trottignon, 106, of Orbigny, and Mme. Roy, of Le Berry, a mere child of 100, remind one of Dutch oil-paintings. Mme. Pierre, 102, of Beaune-la-Rolande, has a look of great kindness and vigour, while Mme. Lanoix, 103, of La Demi-Lune, suggests a contemplative Mr. Punch. Among the men, M. Dufour, 101, of Sarlat, stands out as perhaps the most dogged and robust, but M. Delbos, of Dampniat, carries his 100 years so lightly that he would pass muster in any assembly of sexagenarians. There are also two separate portraits of Mme. La Baronne de Reinach, one at the age of 20 and the other at 102. The countenance of this lady, who still drinks her kirsch every evening, would seem to be almost impervious to time.

### TICS IN YOUNG CHILDREN

THE authors of a monograph,<sup>1</sup> one of a series on child development, have made a praiseworthy attempt to obtain data by objective methods on the incidence and characteristics of tics in small children, and to present them in a clear and unbiased manner. Half of the work is devoted to an historical survey, in which justice is done both to the neurological and the psychological aspects of the subject. There follows an account of the authors' investigations, which were made on a group of 25 children aged two to five, and of 32 children aged five to six, observed under different conditions in a nursery school and a kindergarten. A series of tables demonstrates the variety of tics observed during half-hour periods, their frequency, and the ages of the subjects. The same children were re-examined under varying conditions—free play, "circle play," and while lying down in relaxation. Analysis of the results showed no difference in the incidence in girls and boys, but a steady increase with the age. The influence of occupational factors was difficult to assess, but the frequency of tics was greatest during circle play, when "gross bodily movements" were most under restraint. It is unfortunate that the number of children examined was too small to furnish reliable evidence, for investigations of this kind may well form the basis of useful research on the ætiology of superfluous movements.

<sup>1</sup>The Study of Tics in Pre-school Children. By William E. Blatz and Mabel Crews Ringland. University of Toronto Studies, Child Development Series No. 3. University of Toronto Press; London: Humphrey Milford, Oxford University Press. 1935. Pp. 58. 3s.

## NEW PREPARATIONS

**EULYKOL** is a mixture of the phenylethyl esters of a selected fraction of the acids of *Hydnocarpus* oil; it is sometimes called "phenylethyl hydrocarbate." It has been shown clinically that hydrocarbate esters are capable of clearing up patches of lupus vulgaris and in investigations at the Wellcome Chemical and Physiological Research Laboratories it was found that phenylethyl esters were the least irritant and the most readily absorbed. By eliminating the small, uncrystallisable portion of the total fatty acids, it has been possible to prepare phenylethyl esters possessing a minimum irritant action. Eulykol is usually administered by intradermal injection, and favourable results are reported from its use. It is prepared by Burroughs Wellcome and Co. (Snow Hill Buildings, London, E.C.1) under a British patent, and is now available in bottles of 25 c.cm.

**VASOBROMAN**, made by Gedeon Richter (Great Britain) Ltd., of 1, Hardwick-street, E.C.1, is recommended as useful in relieving high blood pressure and associated symptoms. Each tablet is stated to contain theobromine calcium salicylate, grs. 4, papaverine hydrochloride gr.  $\frac{1}{2}$ , and bromisovaleryl carbamide grs. 3, and the dose suggested is one tablet thrice daily.

**SANATORIUM TREATMENT IN SWEDEN.**—The 80-bed private Swedish sanatorium of Sävsjö, the largest of its kind in Sweden, has issued a pamphlet dealing with its activities and the advantages it has to offer to foreigners. It is about one English mile from Sävsjö railway station on the main line between Malmö and Stockholm. The terms are from Kr.9 to 12.50 per day.

## Vacancies

For further information refer to the advertisement columns

- Accrington, Victoria Hospital.—H.S. £150.  
 Adelaide Children's Hospital, South Australia.—Two Res. M.O.'s. Each £100.  
 Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.  
 All Saints' Hospital, Austral-street, West-square, S.E.—Res. H.S. At rate of £100-£150.  
 Ashford Hospital, Kent.—Res. M.O. £150.  
 Ashton-under-Lyne District Infirmary.—Res. Surg. O. At rate of £200.  
 Aylesbury, Royal Buckinghamshire Hospital.—Sen. Res. M.O. At rate of £200.  
 Birmingham, Erdington House.—Asst. M.O. £650.  
 Bolton Royal Infirmary.—H.P. £200. Also two H.S.'s. Each £125.  
 Bradford Royal Infirmary.—H.P. At rate of £135.  
 Brighton, Borough Infectious Disease Hospital and Sanatorium.—Sen. Res. M.O. £400.  
 Brighton, Royal Alexandra Hospital for Sick Children.—H.P. £120.  
 Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.  
 Bristol Eye Hospital.—Jun. H.S. At rate of £100.  
 Bristol Royal Infirmary.—Medical and Surgical Registrars. Each £400. Also Sen. Res. M.O. £200.  
 Cambridge University.—E. G. Fearnside's Scholarship for Clinical Research, &c.  
 Cardiff, King Edward VII. Welsh National Memorial Association.—Res. M.O. for Kensington Hospital. £350.  
 Cardiff, Llandough Hospital.—Jun. Res. M.O. At rate of £100.  
 Charterhouse Rheumatism Clinic, 9 $\frac{1}{2}$ , Hallam-street, W.—Hon. Clin. Asst.  
 Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100.  
 Children's Hospital, Hampstead, N.W.—Res. M.O. At rate of £150.  
 City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Surg. and Med. Regs. £225 and £175 respectively.  
 City of London Maternity Hospital, City-road, E.C.—Jun. Res. M.O. At rate of £80.  
 Colchester, Essex County Hospital.—H.P. £150.  
 Connaught Hospital, Walthamstow, E.—H.S. and Cas. O. Each at rate of £100.  
 Coventry and Warwickshire Hospital.—Res. H.P. £160.  
 Croydon General Hospital.—Hon. Anaesthetist. Also Hon. Anaesthetist to Dental Dept.  
 Derby, Derbyshire Royal Infirmary.—H.S. £150.  
 Doncaster Royal Infirmary.—H.S. £175.  
 Dreadnought Hospital, Greenwich, S.E.—H.P. and H.S. Each at rate of £110.  
 Dunedin, N.Z., Otago Hospital.—Radiotherapist. £300.  
 Ealing, King Edward Memorial Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £200 and £150 respectively.  
 Eastbourne, Royal Eye Hospital, Pevensey-road.—H.S. £100-£175.  
 East Ham Memorial Hospital, Shrewsbury-road, E.—H.S. to Spec. Depts. and Cas. O. At rate of £120. Also Hon. Ophth. Surgeon.  
 Edenbridge District Hospital.—Hon. Pathologist.  
 Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Hon. Asst. Phys. Also H.P., three H.S.'s, and Obstet. Surgeon. Each at rate of £50.  
 Grimsby and District Hospital.—Hon. Ophth. Officer.  
 Holl, Norfolk, Kelling Sanatorium.—Second Asst. Res. M.O. £350.  
 Hospital for Sick Children, Great Ormond-street, W.C.—Ophth. Surgeon.  
 Hospital for Tropical Diseases, Gordon-street, W.C.—H.P. At rate of £120.  
 Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.  
 Hull Royal Infirmary.—H.S. to Ophth. and Ear, Nose, and Throat Dept. At rate of £150. Also H.S. to Sutton Branch Hospital. At rate of £160.  
 Ilford, King George Hospital.—Hon. Asst. Dermatologist.  
 Kettering and District General Hospital.—Second Res. M.O. At rate of £125.  
 Kidderminster and District General Hospital.—H.S. £150.  
 Lancashire County Council.—Asst. County M.O.'s. Each £800.  
 Manchester City Mental Hospital, Humberstone.—Sen. Asst. M.O. £700. Third Asst. Res. M.O. £350. Also Locum Tenens Asst. M.O. 10 guineas.  
 Llanelly and District General Eye Hospital.—Res. Med. Supt. £300.  
 London County Council.—Practitioners. 7s. 6d. and 10s. a visit.  
 London Hospital, E.—Hon. Asst. Surgeon to Ear, Nose, and Throat Dept.  
 Manchester, Ancoats Hospital.—H.S. At rate of £100.  
 Manchester, Hulme Dispensary, Dale-street.—Res. M.O. £250.  
 Manchester Royal Children's Hospital, Pendlebury.—Res. Surg. O. At rate of £125. Also Res. H.S. At rate of £100.  
 Manchester Victoria Memorial Jewish Hospital.—Cas. H.S. At rate of £125.  
 Millwall (Isle of Dogs) Treatment Centre.—M.O. £66.  
 Mount Vernon Hospital, Northwood.—H.S. At rate of £150.  
 Murthly Perth District Asylum.—Med. Supt.  
 National Hospital for Diseases of the Nervous System, Queen-square, W.C.—Asst. Registrar. £200.  
 Newcastle-upon-Tyne Hospital for Sick Children.—Asst. Hon. Physician to Skin Dept.  
 Norwich, Norfolk and Norwich Hospital.—Cas. O. £120.  
 Nottingham General Hospital.—H.S. At rate of £150.  
 Nottingham General Dispensary, Gregory Boulevard Branch.—Res. Surgeon. £250.  
 Nottingham and Midland Eye Infirmary.—Res. H.S. £200.  
 Oldham, Boundary Park Municipal Hospital.—Asst. Res. M.O. £350.  
 Oldham County Borough.—Asst. M.O.H. and Asst. Tuberc. Officer. £750.  
 Oldham Royal Infirmary.—H.S. to Special Depts. and H.P. at rate of £175.  
 Princess Beatrice Hospital, Earl's Court, S.W.—Res. M.O. At rate of £150. Also Hon. Asst. Surgeon to Ear, Nose, and Throat Dept.  
 Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—H.S. At rate of £100.  
 Queen's Hospital for Children, Hackney-road, E.—Psychiatrist.  
 Queen Mary's Hospital for the East End, Stratford, E.—Hon. Asst. Surgeon, Res. M.O., and two Cas. and Out-patient Officers. Each at rate of £150. Also H.P.'s, H.S.'s, and Res. Anaesthetist. Each at rate of £120.  
 Radium Beam Therapy Research, &c., 16, Riding House-street, W. Asst. M.O. At rate of £250.  
 Relford, Notts, Rampton State Institution for Mental Defectives.—Medical Officer. £515.  
 Rotherham County Borough.—Asst. M.O. £300.  
 Royal Chest Hospital, City-road, E.C.—Surgeon.  
 Royal College of Physicians of London.—Charles Murchison Scholarship in Clin. Med. 20 guineas.  
 Royal Free Hospital, Gray's Inn-road, W.C.—Res. Cas. O. and Res. Anaesthetist. At rate of £150 and £75 respectively. Also Children's Third H.S.  
 Royal Naval Medical Service.—M.O.'s.  
 Royal Northern Hospital, Holloway, N.—Hon. Radiologist.  
 Royal Waterloo Hospital, Waterloo-road, S.E.—H.S. At rate of £100.  
 Salvation Army Mothers' Hospital, Lower Clapton-road, E.—Jun. Res. M.O. At rate of £80.  
 Sheffield Royal Infirmary.—Ophth. H.S. At rate of £120.  
 Sheffield University.—Demonstrator in Anatomy. £300.  
 Smethwick County Borough.—Asst. M.O.H. and Asst. School M.O. £350.  
 Southampton, Isolation Hospital and Sanatorium.—Jun. Res. M.O. £200.  
 South Africa, Northern Free State General Hospital, Kroonstad.—Med. Supt. £1000.  
 St. John's Hospital, Lewisham, S.E.—H.S. At rate of £100.  
 Stockport Infirmary.—H.S. and Cas. O. £150.  
 Sunderland Royal Infirmary.—H.S. and H.P. Each £120.  
 Truro, Royal Cornwall Infirmary.—Hon. Surgeon.  
 University of London, King's College, Strand, W.C.—Asst. Lecturer and Research Worker. £300.  
 West London Hospital, Hammersmith-road, W.—Res. Asst. Surgeon. £200. Med. Reg. to Children's Dept. £100. Also two H.S.'s and Res. Cas. O. Each at rate of £100.  
 West Malling, Kent, Leybourne Grange Colony for Mental Defectives.—Asst. Res. M.O. £350.  
 Wolverhampton Royal Hospital.—H.P. and H.S. At rate of £125 and £100 respectively.  
 Worksop, Victoria Hospital.—Sen. and Jun. Residents. £150 and £120 respectively.

## LATE RESULTS IN THE OPERATIVE TREATMENT OF INTRACRANIAL TUMOURS \*

By HUGH CAIRNS, M.B. Adelaide, F.R.C.S. Eng.  
 SURGEON IN CHARGE OF THE DEPARTMENT OF NEURO-SURGERY, LONDON HOSPITAL

DURING the year September, 1926, to September, 1927, it was my privilege to act as assistant resident surgeon in the clinic of Dr. Harvey Cushing at the Peter Bent Brigham Hospital, Boston, and to make a report on the immediate results of the year's work to the Medical Research Council.<sup>3</sup> The present report is concerned with the ultimate fate of 135 patients with verified intracranial tumours who left hospital alive after having been treated during 1926-27 by a major intracranial operation (Tables I. and II.).

TABLE I

Verified Intracranial Tumours Treated by Operation During 1926-27

Tumours partly or wholly removed at operation in 1926-27 .. .. .	148
Tumours first verified at necropsy .. .. .	5
Tumours not surgically disclosed but found and verified at secondary operation in later years .. .. .	4

Total .. .. .	22	72	63	157

\* For various reasons these figures are not identical with those given in Table VI. of the report to the Medical Research Council.<sup>3</sup> Thus, 61 gliomas were cited in the original report, whereas now there are only 59. Two of the original cases have since been reclassified, after further operation, one as a sarcoma, another as a meningioma.

Contact has been maintained with every one of these 135 patients during the years between 1927 and 1935; of those who died the time and manner of death is in most cases known; with those who are alive regular correspondence has been exchanged and many have been examined from time to time. This follow-up work is done by Dr. Louise Eisenhardt, formerly of the Peter Bent Brigham Hospital and now in charge of the Brain Tumour Registry at New Haven, where records of Dr. Cushing's 2000 and more verified brain tumour cases<sup>9</sup> are kept. The fact that not one of these 135 patients has been lost

sight of indicates the thoroughness of the system. Without Dr. Eisenhardt's work the present study could not have been undertaken. When I revisited the United States in the autumn of 1935 she kindly collected the necessary material for me, with the help of Miss M. Stanton. Through the kind interest of Dr. Cushing I was able to examine personally many of the survivors of the series.

The primary aim of such an investigation as this is to estimate the lasting value of surgical treatment of intracranial tumours. Table II. shows the survival-rates of the patients operated on in 1926-27. Of 135 patients discharged from hospital 63 were alive when last heard from seven to nine years later. With intracranial tumours a survival table tells us little. This one supports in a general way the impression that about half of all intracranial tumours coming to operation are benign and the other half malignant, but it does not indicate the value of treatment; for a patient may live indefinitely after removal of an intracranial tumour and yet be so maimed that his life is a burden to his relatives and to himself. What we need to know is the period of useful life of a patient after operation.

To assess the value of surgical treatment it is obviously necessary to consider each pathological type of tumour separately. Not only does the life-history of intracranial tumours vary as between one type and another, but in some instances the criteria by which results can be judged also differ. For example, some patients are operated upon to relieve loss of sight rather than to save life, and in these the results of treatment must be judged by the condition of their eyesight and not by longevity.

Table III. gives a detailed analysis of the late results according to pathological type. In this and the succeeding table the duration of life after operation is given in years. A certain number of patients have had more than one intracranial operation and the duration of life is calculated from the time when the tumour was first removed. For example, a patient was operated on during 1926-27 for recurrent meningioma, the first operation having been performed in 1919; this patient died in 1932 and the duration of life was thus 13 years. In the last column of Tables III. and IV. is recorded the longest post-operative survival period so far achieved among the 2000 tumour cases of the collection for each type of tumour. These compensate in some measure for possible errors of judgment, due either to the small number of cases observed in one year, or to the fact that only 8-9 years have elapsed since operation. †

### GLIOMAS

The course of the gliomas in this series is shown in Table IV.

*Glioblastoma multiforme.*—This is typically a rapidly growing tumour of the white matter of the cerebral hemisphere of middle-aged and elderly people. It is an invasive tumour and usually contains areas of necrosis and hæmorrhage. At times it contains one or more cysts. The illness runs as a rule a fairly rapid course, measurable in weeks or months. At operation the tumour may appear to be sharply defined from the surrounding softened white matter, but, even after an apparently complete removal, in

† These figures have kindly been supplied by Dr. Eisenhardt from an unpublished paper presented before the Association for Research in Nervous and Mental Disease, Dec. 28th, 1935.

\* The full report is being published in the Yale Journal of Biology and Medicine, May, 1936.

most cases it quickly recurs. Radiation in various forms usually fails to prevent recurrence.

In this series there were 8 cases of glioblastoma multiforme. In 6 cases removal of tumour at operation appeared to be complete, in the other two partial. In one patient a second operation was done and the tumour was again removed, 4 months after the first operation; the patient died 5 months later. In all cases the tumour recurred after a brief interval and every one of the patients soon died. The shortest survival period from the time of operation was 2½ months, the longest 14 months, the average about 6½ months. The longest period of freedom from symptoms after operation was 2 months.

*Cerebellar Medulloblastoma.*<sup>1 7</sup>—This is another very unfavourable type of glioma. Arising usually in the vermis of children and young adults it grows rapidly and quickly produces hydrocephalus. The diagnosis of cerebellar tumour rarely presents difficulty. At operation the tumour can be shelled out apparently completely, but soon, usually within a year, there is recurrence. Metastases occur in the cerebral and spinal subarachnoid spaces and in the ventricles.<sup>4</sup> X rays or radium produce prompt amelioration of symptoms, for the tumour is at first very sensitive to radiation, more so than any other form of intracranial tumour. But as times goes on radiation ceases to give relief and the patient dies.

In this series there were 5 cases of cerebellar medulloblastoma. All died at intervals of 2 to 19 months after operation. The average survival period

was 13 months. In van Wagenen's series of 17 cases it was 14.5 months. When Cushing<sup>7</sup> reported the medulloblastomas in Lund, only 3 of the 61 cases he had treated up to that time were still alive.

Though the survival period is short the proportion of it that may be regarded as useful life is usually high. The patients recover quickly and completely from operation provided hydrocephalus has been relieved, and with regular courses of X ray treatment are able to get about with every appearance of normality and happiness for about a year. The period of final illness is usually mercifully short, though not invariably so, for sometimes incapacitating symptoms arise from spinal metastasis when there is no clinical evidence of recurrence within the cranium.† But in the majority of cases, short as the respite is, the parents of the patient seem so grateful for this extra time that it is impossible to conclude that surgery is not worth while in this variety of tumour. And that is just as well, for it is practically impossible to distinguish clinically between this tumour and the benign astrocytoma (q.v.) that occurs in the same situation.

*Cerebral Medulloblastoma.*—Occasionally medulloblastoma has been described as occurring in the cerebral hemisphere, but with far less frequency than in the cerebellum. Moreover, cerebral medulloblastomas do not appear to have the same life-history

† Hence the importance after operation of prophylactic radiation of the spinal canal.

as cerebellar medulloblastoma, nor, as a rule, the same radio-sensitivity. There were two gliomas of the cerebral hemisphere in this series that were classified as medulloblastomas, but this interpretation of the histological picture is not free from possibility of error, and, moreover, the group is too small to justify conclusions. One patient died 5 months after operation without improvement. The other patient survived nearly 5 years.

*Cerebellar Astrocytoma.*<sup>8</sup>—This proves to be one of the most satisfactory intracranial tumours to deal with surgically. Composed of fully differentiated astrocytes, it occurs chiefly in young adults and children in the vermis and lateral lobes of the cerebellum and appears to be almost invariably quite circumscribed and benign. If all the tumour tissue visible to the naked eye is removed at an operation in which the lesion is adequately exposed, the tumour does not as a rule recur, though in this connexion it must be noted that symptoms of recurrence after incomplete operations may be delayed for as long as eleven years, and perhaps longer.

In this series there were 4 young female patients with cerebellar astrocytomas. In one case only part of the tumour was removed, and the patient died after a second attempt to remove the tumour fourteen months later. In the other cases the tumour was completely removed during 1926-27 and all three patients were well, in full work, and free from symptoms when last heard from seven to nine years after operation, with the exception that one complained of occasional headaches and tremor of the left hand and foot. This patient and another had married since operation, and each had borne two healthy children. The third was seen recently by me and was free from symptoms.

*Cerebral Astrocytoma.*—Astrocytoma of the cerebral hemisphere differs from the cerebellar astrocytoma in being less sharply defined and not wholly composed of astrocytes, but often containing an admixture of oligodendroglia and other cells. Furthermore, the astrocytes are often immature and some tumours show mitotic figures. These tumours are often difficult to remove completely, and sometimes they infiltrate the brain to such a remarkable degree that complete removal, short of removing the cerebral hemisphere, is impossible. Recurrence after apparently complete removal of the tumour is common, whereas in cerebellar astrocytoma it is rare.

In this series there were 15 cerebral astrocytomas, a remarkably large number. The survival periods are shown in Table IV. and it can be seen that the majority (all except 4) died within three years. Of the 15 patients 8 had a second operation for recurrence of tumour. The average survival period for the whole group was 37.0 months.

Of the patients who survived operation for more than three years one, a young man with a cystic left temporal astrocytoma (Cushing,<sup>6</sup> Case 9), lived nine years from the time of his first operation, being free from symptoms and doing active farm work for six of those years. Another, a man with a cystic right parietal astrocytoma (Cairns,<sup>3</sup> Case 8), blind from secondary optic atrophy before his first operation, was still alive when last heard from seven and a half years after operation. Another, a woman with a large solid left occipital astrocytoma (Cairns,<sup>3</sup> Case 9; Horrax and Putman,<sup>13</sup> Case 6), subtotally removed, was free from symptoms of recurrence of tumour for nearly seven years after operation, but died six months after a further operation for recurrence.

There is little doubt that there is considerable variation in the rate of growth of individual astrocytomas. Whether this can be explained on a histological basis has not yet been established. With the improvements in diagnosis and operative technique which have been taking place in more recent years it is reasonable to expect that in the future permanent cures of some of the more benign cerebral astrocytomas will be obtained.

*Oligodendrogloma.*—This tumour also appears to vary considerably from case to case in its rate of growth and method of spread. There were only two cases discharged from hospital alive in this 1926-27 series. In one, death occurred suddenly one year and nine months after removal of the tumour, from what was thought to be cerebral hæmorrhage. The other patient lived for nearly nine years from the time of his operation, and during that time had three further operations for removal of recurrent tumour. He was able to conduct his business satisfactorily for about six of these years, but the benefit of removal of tumour became less with each succeeding operation.

*Astroblastoma.*—In this tumour there appears to be considerable variation in the rate of growth. Of the 4 patients in this series from whom tumours of this type were removed one lived three months and another thirteen months; the third had previously had a tumour removed in May, 1926, and a recurrent tumour was removed six months later; after that she lived for over four years.

The fourth case is one of the most satisfactory cases in the whole series, and the result of operation is one that would not have been predicted when the patient was in hospital. The patient, a middle-aged woman, had suffered for five months from profound and progressive mental disturbance followed by severe frontal headache. At operation a cystic and solid tumour was removed from the right frontal lobe (Cairns,<sup>3</sup> Case 31). Apart from one convulsive seizure one year after operation she had remained in perfect health up to the time when she was last seen nine years after operation. It is necessary to add that the histological interpretation of this tumour has been difficult. Dr. Eisenhardt's opinion after further study in 1935 was that it was an astroblastoma. Whatever the exact nature of the tumour may be, the clinical picture before operation suggested that it was a tumour of rapid growth and one that might not respond favourably to surgical treatment.

#### PITUITARY ADENOMA

During the year 1926-27 29 patients were operated on for pituitary adenoma (Table V.). At that time

TABLE V.—*Pituitary Adenomas*

Total	..	..	..	..	..	..	29
Chromophil adenomas	..	..	..	..	..	5

Living 7-9 years after operation	..	..	..	..	..	19	29

\* As the initial or only operative procedure.

it was customary in the clinic to treat pituitary adenomas by the trans-sphenoidal operation unless there was difficulty in excluding some suprasellar tumour, such as suprasellar meningioma or cranio-pharyngioma. Since 1927 the transfrontal approach has been the more routine procedure. A number of

patients operated on by the trans-sphenoidal route during 1926-27 have since undergone a second operation by the transfrontal route.

Nine patients have died since leaving hospital, from intracranial or nasopharyngeal extensions of tumours, from intercurrent disease, and in two cases from coma for which no satisfactory cause was found at necropsy. In these cases there was no ketosis. The working ability of the 19 survivors is shown in Table VI.

TABLE VI.—*Pituitary Adenoma*  
*Working Ability of 19 Survivors*

No information.	Full work.	Intermittent work.	No work.
3	11	1	4 } Mental symptoms 2 Blindness 1 Headache 1

Some of the patients who were in full work when last heard from had previously suffered from periods of ill-health since the time of operation. Many still have disturbance of reproductive function. Mental symptoms have appeared in two patients, probably as a result of intracranial extension of the tumour. Attacks of unconsciousness as isolated incidents have appeared in four patients. Periods of weakness and extreme drowsiness lasting a week or more have marked the course of several patients both with chromophil and chromophobe adenomas. One patient has had an attack of vertigo. Bouts of headache, sometimes accompanied by diplopia, have occurred in some cases. Constipation, gastric disturbance, excessive appetite, and obesity are other symptoms mentioned. It seems likely that operation in its present form does not stay the course of the endocrine manifestations, even though it may diminish their rate of progress to some extent.

Of the 19 survivors 12 had good sight (6/12 or better in both or one eye) seven to nine years after operation; 6 had severe loss of vision; and the condition of sight of the other was unknown. Of the 9 fatal cases 5 had good vision at the time of their death and 4 were almost or quite blind. Critical judgment of the value of operation in preserving vision is a difficult matter. So far as I am aware there is no good series of control cases in existence, yet it is known that, while the general tendency is one of progressive hemianopia and reduction of visual acuity, there are nevertheless cases in which chromophil adenoma, and probably also chromophobe adenoma, exist for many years without producing more than a slight degree of bitemporal hemianopia, and other cases in which the fields and visual acuity may improve spontaneously after a fairly advanced stage of defect has been reached. In this series, also, it is not easy to test the relative merits of different forms of treatment. X ray treatment was given at one time or another to most of the patients, but it is difficult to draw any conclusions as to its value, because of its close but variable relation to operation, and the lack of any immediate dramatic effect.

The series does give, however, some important and unexpected information about the results of the trans-sphenoidal operation. Improvement of vision after this operation has been usually delayed and gradual, and the condition of sight at the time when the patient was discharged from hospital gives no true indication of what the ultimate result will be.

Thus, a man aged 39, a sleepy apathetic rather obese individual with a large chromophobe adenoma, who had been virtually blind for four months (3/200 in the right eye and no P.L. in the left), ultimately improved after trans-sphenoidal operation to a surprising degree. At the time of discharge from hospital there was little improvement, but eighteen months later he could see enough to walk about by himself; three years after operation he could see well enough to resume his work as manager of a shop, and during the next five years, up to the time when I last saw him, he had not lost a day at work. Nine years after operation his vision was 20/30 in the right eye and the other eye was blind. Although he was free from symptoms there was clinical and radiological evidence of a large tumour at the base of the skull.

While the transfrontal operation is now the method of choice in most cases, yet in cases of extreme visual loss with a large intrasellar tumour it is probable that better results may sometimes be achieved by the trans-sphenoidal operation.

#### MENINGIOMAS

The meningioma or dural endothelioma is a tumour that is attached usually to the dura and grows slowly, embedding itself in the brain in the process, but so gradually that the tumour frequently attains a large size before it produces serious symptoms. These tumours are often extremely vascular and consequently difficult to remove. But they are usually quite circumscribed, and have been considered to give the most favourable outcome of any intracranial tumour in cases where the patient has survived complete removal.

Of the 31 patients with meningiomas 5 died after operation. Of the 26 survivors 8 have since died at varying intervals, all from recurrence of tumour (Table III.). In 6 of these cases the tumour was known to have been only partly removed at operation, but in the other 2 removal of the tumour had apparently been complete. These last 2 were cases of recurrent meningioma in which the first removal of tumour had been undertaken some years previously, when there was still no clear understanding the prime importance of removing all bone and dura in the slightest degree suspect through invasion of tumour cells. Another patient, operated on for the first time in 1926 for removal of a large bilateral sagittal meningioma with a large overlying neoplastic hyperostosis, was left at the conclusion of operation with a small fragment of tumour tissue in the superior longitudinal sinus. Symptoms of recurrence of tumour appeared about a year later and were ultimately fatal. Recurrence is not unknown up to seventeen years after the removal of a meningioma.

From seven to nine years after operation 18 patients were alive and well. Of these, 8 were completely well or suffering only from minor symptoms, and were at work. A further 6 were at work but had major symptoms; 3 of them suffered from visual loss which had been present before operation; 1 had slight mental symptoms which had been present before operation; and 2 had occasional fits. The remaining 4 patients were living but unable to work, 2 because of the presence of an actively growing tumour which was irremovable, 1 because of blindness that was present before the tumour was removed, and 1 because of mental symptoms which were present before operation.

The frequency of post-operative epilepsy after removal of supratentorial tumours is probably much higher than has hitherto been realised. In 8 of the 14 supratentorial meningiomas of this series occasional epileptic manifestations persisted after the

tumour was wholly or subtotally removed. Often they were of minor character and infrequent, and in none did they prevent the patient from working. But cases may arise in which post-operative epilepsy greatly mars what would otherwise be a very satisfactory surgical result, and these present a problem of treatment that still awaits solution.

Although it has long been known that a meningioma may invade the overlying bone, and although malignant meningiomas have been encountered by most neurosurgeons and reported by a few, this tumour has usually been regarded as the most benign of intracranial tumours. Certain cases in this series provide excellent late results of removal, but a study of the series as a whole provokes the question whether the results are ever likely to be so uniformly good as the late results of removal of cerebellar astrocytomas and hæmangiomas, and there is evidently still much to be done in perfecting the operative treatment of meningiomas. The treatment here discussed is, of course, that given during 1926-27, and since that time advances in technique have already been made, perhaps more for meningiomas than for any other variety of tumour.

#### ACOUSTIC NEURINOMAS

During 1926-27 10 cases of acoustic neurinoma were operated on by the method of intracapsular extirpation, the greater part of the capsule with a shell of tumour tissue being left in place (Table III.).

*Dead* (2).—One patient died in hospital soon after operation, and another died three years after operation from what was probably bronchiectasis following chronic dysphagia.

*Living* (8).—When last heard from seven to nine years after operation three were unable to work and were completely or severely incapacitated by ataxia. One had severe disturbance of gait, but there was no information about his working capacity. One had suffered from severe unsteadiness after operation, and then returned to work for about three years, and had later become ill again with high blood pressure, gastric ulcer, and recurrence of his original symptoms. One was able to do light work.

Two were in full work. One of these was handicapped by greatly reduced vision which had been present before operation. The other patient when seen eight years after operation was found to be in practically normal health. She said that for about a year after operation she had suffered from severe disability of the arm and leg corresponding to the side of the tumour, and that she had not been able to resume a normal life until two years after the operation. It is probable that the story of prolonged post-operative disability given by this patient is by no means unusual.

The symptoms of acoustic tumour before operation, as is well known, can be grouped for the most part in three categories: those due (1) to rise of intracranial pressure; (2) to cranial nerve palsies; (3) to impaired coördination of movement. After operation, though there is an occasional case in which an internal hydrocephalus is merely converted into an external hydrocephalus, rise of intracranial pressure is usually relieved and blindness prevented; and the residual disability is mainly one of disturbed coördination. With incomplete operations disturbance of balance may be more pronounced than it was before. Even with complete removal of the tumour it may persist for a year or more after operation.

A study of the 1926-27 cases shows the serious nature of the problem. Of 8 patients, 6 were left with severe disturbances of balance, lasting through a period of years after operation. Further attempts have been made to improve 5 of them by secondary

operations with removal of more tumour, and 2 of them have each had two secondary operations. None of these patients has been seen and fully examined recently, and the amount of improvement that has resulted cannot therefore be accurately gauged; but from letters and reports it is doubtful whether the improvement has been great. In none of the secondary operations was the tumour completely removed.

Increasing experience may show that in some cases it is easier to remove the tumour completely at a second operation after an interval than it was at the first. The tumour may not then be so vascular and the formation of cystic collections of fluid may facilitate its removal. Dissatisfaction with the results of previous intracapsular operations led Cushing<sup>6</sup> in 1928 to introduce a more radical exposure, obtained by removing the lateral cerebellar lobe overlying the tumour. Since that time much more radical operations have been done, and it is likely that the late results of 1929 would prove better than those of the year at present under consideration.

Another way of attacking the problem advocated by Dandy<sup>11</sup> and by Olivecrona<sup>12</sup> is to remove the tumour completely. With increasing experience there is no doubt that most neurosurgeons are tending to do more and more radical operations of this nature, but the mortality is likely to be high if this method is applied indiscriminately. So much depends on the consistence and vascularity of the tumour, on the firmness of its adherence to the side of the pons and restiform body, on the condition of the patient, and on the ease with which the early stages of the operation are accomplished. Probably there will always be some cases in which it is necessary to do two-stage operations. The problem is worthy of the most earnest and sustained attention because the tumour is quite benign.

#### CHOLESTEATOMA

There were 2 patients in this group, one with a tumour of the anterior and middle fossæ not in any way connected with middle-ear disease, and the other with a tumour in the cerebellopontine angle. Both these patients were well seven years after operation although in neither case had removal of the tumour capsule been complete. The evidence of these cases, so far as it goes, suggests that it is unnecessary to remove the capsule of a cholesteatoma.

#### BLOOD-VESSEL TUMOURS

One of the most favourable varieties of intracranial tumour is the hæmangioblastoma of the cerebellum, if it can be completely removed, but that fact is not shown by this series of cases, though it is well established by previous report.<sup>10</sup> In 1926-27 one patient died after complete removal of a cerebellar hæmangioblastoma. In another it was found at operation that the tumour could not be removed. This patient was still alive seven years after the decompression operation, but was seriously incapacitated by ataxia of all four limbs.

There were 2 cases of arterio-venous angioma of the cerebral hemisphere, and both patients were alive eight years after operation. In one the result was poor, for the patient suffered from right hemiparesis and aphasia and frequent focal fits. In the other the result was satisfactory. This case provides fairly good evidence of the value of X ray treatment in arteriovenous angioma.

## GRANULOMAS

One patient with a left frontal parasagittal granuloma, thought to be a gumma, died two years and nine months after operation of prostatic abscess, pelvic cellulitis, and peritonitis. One patient with a cerebellar tuberculoma, partly removed on the supposition that it was a meningioma, died four months after operation, death being preceded by progressive cranial nerve palsies and other symptoms of posterior fossa disturbance. Another patient from whom a left temporal tuberculoma had been removed was alive at the time of this report, but suffered severely from epilepsy. For more extensive information about the late results of surgical treatment of tuberculomas the reader is referred to the paper of van Wagenen<sup>22</sup> though it is probable that further experience will be less unfavourable than his.

## METASTATIC TUMOURS

Of the patients with metastatic tumours 1 died in hospital and 7 were discharged alive (Table III.). Of these, 5 died within five months of operation, but the other 2 lived more than two years. One of them had respite from hemiplegia for six months after operation, but then for a long time before death lived a vegetative existence. The other had fifteen months of useful work as a tramdriver between his operation and his death. This patient had a large right parietal metastatic carcinoma from an unknown source, involving pericranium, bone and dura, and projecting into the cranial cavity like a meningioma. Clinically there had been a lump on the head and before operation meningioma had been suspected.

A much larger series of metastatic tumours from this clinic, studied by Meagher and Eisenhardt<sup>16</sup> showed that the patients survived cranial operations for an average of only six weeks, but Oldberg<sup>17</sup> has reported two remarkable cases in which there was freedom from intracranial symptoms for two years after the cerebral tumour was removed.

## MISCELLANEOUS TUMOURS

Two patients with tumours of the skull, one a myeloma and the other a sarcoma, died about two months after operation. One patient with a fibrosarcoma in the right temporal lobe died one year after operation. The other 4 patients in this group were living seven or more years after operation. Their respective lesions had been a hydatid cyst of the right parietal lobe, a simple cyst of the cerebellum, and an osteoma of the orbit. The first patient suffered from acute alcoholism and epilepsy, and the other two were quite free from symptoms.

**IRISH HOSPITALS SWEEPSTAKES.**—The draw for the eighteenth in the series of sweepstakes in aid of the Irish hospitals was held in Dublin on May 22nd and 24th. It was reported that the receipts on the present draw showed an advance of nearly £50,000 on those on the last sweepstake on the Derby, although the interval for preparation had been eleven days less. The sum that will be devoted to the hospitals from the present sweepstake is £377,973. The total amount collected for the hospitals in the eighteen sweepstakes beginning in November, 1930, is £9,618,186.

## THE DIAGNOSIS OF CARCINOMA OF THE CERVIX IN A VERY EARLY STAGE\*

BY DR. WALTER SCHILLER

PATHOLOGIST OF THE II. FRAUENKLINIK, VIENNA

WHEN 12 years ago the question of how to improve the carcinoma statistics was discussed in the laboratory of the Vienna II. Frauenklinik I made up my mind to try to do it by systematic work. I saw three ways: (1) to improve the operative methods; (2) to improve the radiotherapy; (3) to find a method of early diagnosis.

An improvement of the operative technique hardly seemed possible, both radical operations—Wertheim's abdominal and Schauta's vaginal—being the best that operative technique can achieve. The small modifications of these methods occasionally indicated do not change the results. Improvement in X ray or radium therapy is not possible with ordinary apparatus, which to-day is at its maximum efficiency. An improvement of radiotherapy might be obtained only by applying stronger or more efficient rays. There therefore remains, per exclusionem, only the third way—the improvement of early diagnosis.

### The Pathology of Early Cancer

The first question I put to myself was: What do the early, the earliest, stages of a cancer of the cervix look like? They need not necessarily look like a miniature reproduction or a small piece of the fully developed carcinoma. The present definition of cancer is not exact; it has developed in the course of centuries into a complex idea and has not been deduced from predefined concepts. The idea of cancer that has become classical concerns the histology both of the individual cells and of the groups of cells in the tumour tissue; neither is sharply defined, but merely empirical. The cellular characteristics are polymorphism and non-conformity of type; the many attempts, however, of latter years to measure or count the nuclei by statistical methods were for practical purposes all failures. The distinguishing feature of the tumour tissue, invasive growth, is generally considered the main characteristic of malignancy. The question arises whether the youngest and earliest stages of cancer are also definitely polymorphous and atypical, as well as invasive. In other words it is a question whether a cancer shows in its earliest stages all the characteristics of the advanced stages; this may be, but is not necessarily so.

Does cancer in its earliest stages—i.e., from the beginning—show all the three qualities on which we usually base our diagnosis of a progressed cancer? Are its cells atypical, polymorphous, and is it invasive? Of these the last is of great diagnostic importance, for to the pathologist whether the cells are polymorphous and atypical is a matter of individual judgment, while invasion can easily be demonstrated.

One of the most interesting and valuable observations was made by Kermauner concerning the borderline between normal and carcinomatous tissue.

He examined most carefully a great number of solid cervical cancers of the uterus to study the way in which the normal tissue is demarcated from the carcinomatous.

\* Part of the Lloyd Roberts lecture delivered in Manchester on May 19th, 1936.

In the great majority (about 95 per cent.) there is a narrow zone between the carcinomatous and the normal epithelium, and in it there is a stroma covered neither by carcinomatous nor by normal epithelium, but which appears somewhat ulcerated owing to inflammatory erosion (Fig. 1 A). We

FIG. 1.—Carcinoma of the cervix. (A) 90-95 per cent. of cases. (B) 5-10 per cent. of cases (see Table I.). (a) Carcinomatous zone. (b) Intermediate zone. (c) Normal epithelium.

call this the zone of demarcation. It forms a sort of neutral area between the carcinomatous and the normal tissue but is not occupied by either. This is the usual picture as it presents itself in the majority of cases. In the remainder (about 5 per cent.) there is a different kind of demarcation (Fig. 1 B). The carcinomatous and the normal epithelium are in a contiguity with a zone of epithelium between them that has about the same thickness as the normal epithelium with which it is in direct connexion but the cells are polymorphous and atypical, corresponding completely with those of the carcinoma on the other side. From the cytological point of view there is no difference between the carcinoma and the epithelial intermediate zone. The characteristics of the three zones according to their cytological and histological state are shown in Table I.

TABLE I.—Marginal Zones of Cancer (Fig. 1 B)

	Polymorphous and atypical cells.	Down-growth.	Ulceration.
(a) Carcinoma	+	+	+
(b) Intermediate zone	+	-	-
(c) Normal epithelium	-	-	-

The question arises of how to classify the intermediate link. Is it carcinoma or normal tissue or is it a sort of transition stage? Kermauner without entering into discussion considered it carcinoma.

The Search for the Youngest Growths

I have attempted to find as early stages as possible in the following way. A really early cancer is one that has escaped diagnosis by the usual speculum examination. If a carcinoma is so big that it can be diagnosed clinically in the ordinary way special means are not required. The aim of my experiments was to work out a method that would enable us to detect such cancers as are lying beyond the limits of clinical visibility.

To state what a young carcinoma looks like it was necessary first of all to get young growths for histological examination. But I was looking for a carcinoma not visible or palpable by the usual methods; consequently it could not be discovered by an ordinary clinical examination. As such a method for finding early cancers had still to be worked out, there was only one possibility of getting young carcinomata for histological examination—namely, by chance. Such a chance would come about with mathematical certainty if enough uteri were examined for the condition of the cervix. To increase the probability I increased the number of examinations as much as possible—i.e., for several years I examined histologically the cervix of every uterus extirpated for whatever reason at our clinic. I examined under the microscope the cervix of every such uterus by several radial sections. There were cases of fibroids, chronic adnexial tumours, hyperplasia of the endometrium,

adenomyosis, &c., the portio vaginalis of which seemed above suspicion. All of these I examined systematically. After having carried on these examinations for a number of years I found a series of cases which could be fitted into several groups, forming an uninterrupted series that began with the already known pictures and by gradual transition led to an as yet unknown early stage (Table II. and Fig. 2). The largest and best developed, Stage I., is in complete accord with Kermauner's findings. The next stage whose pathological area was correspondingly smaller again showed the three zones, but in the first zone of carcinoma there was no ulceration. The youngest stage (III.) showed no down-growth either; thus the zone of carcinoma and the superficial intermediate zone are alike. These three stages form a complete series with gradual transitions.

If in advanced cancer the superficial layer described by Kermauner and Schottländer is considered part of the carcinoma and consequently carcinoma itself then we are justified in considering the superficial layer of Stage I. as carcinoma. If this superficial layer is considered carcinoma then the superficial layer of Stage II. is carcinoma as well, because the secondary ulceration of the surface cannot establish the character of carcinoma. The last and perhaps the most difficult question to be settled is whether Stage III., which has only the superficial layer, is to be classed as carcinoma. In consideration of the logical development of our ideas we must go a step further. From the morphological and cytological point of view there is no difference whatever between the superficial layer of the margin area of extended carcinoma and the superficial layers that are found by themselves and isolated, which I described as Stage III. The character and pattern of the cells

FIG. 2.—Carcinoma of cervix. The three early stages (see Table II.). (a) Carcinomatous zone. (b) Superficial intermediate zone. (c) Normal epithelium.

TABLE II

	I.			II.			III.	
	a	b	c	a	b	c	ab	c
Polymorphous and atypical cells ..	+	+	-	+	+	-	+	-
Invasion .. ..	+	-	-	+	-	-	-	-
Ulceration .. ..	+	-	-	-	-	-	-	-

and the structure of the epithelium are identical, and having diagnosed the superficial layer of the margin as part of the carcinoma in spite of its not showing down-growth we are bound to consider the isolated layer as carcinoma. From our experience that down-growth is not one of the positive characters of carcinoma, and that the first stages of a carcinoma are characterised only by the cytological character not by the histological conditions—that is, by invasion—we come to a new conception of carcinoma, based

exclusively upon the cellular structure and not upon the histological localisation in general and the down-growth in particular.

According to the diagnosis given above, the development of a solid carcinoma of the squamous epithelium of the cervix is as follows:—

First a part of the epithelium of the surface, beginning at the external os, is changed into carcinoma—i.e., into a superficial layer analogous to the superficial layers of the marginal zones of advanced cancers. Next begins the invasive growth at the central part nearest to the external os, with plugs from the superficial layer penetrating into the depths. The last phase is the inflammatory breaking down of the surface by which the carcinoma ulcerates on the surface. This occurs rather late, so that a case with distinct ulceration may no longer be considered an incipient carcinoma.

The genuine early cancers consist of a superficial layer, first without and then with cones penetrating deeply. Therefore all early growths have a smooth surface, the superficial layer lying quite flush with the normal surface and showing no papillary growth, recesses, or ulceration. This is what makes it so difficult to diagnose the first stage of cancer, because the superficial layer is not distinguished either in colour or in form from the normal surrounding epithelium. I convinced myself of this by examining a large number of operation specimens. Only in isolated cases, which doubtless are the minority, the carcinomatous layer—i.e., the incipient cancer—shows certain differences that are revealed only by very exact observation.

These differences are:—

(1) The carcinomatous superficial layer is sometimes slightly higher than its surrounding—i.e., its margins are somewhat elevated from the surrounding epithelium. This difference of level is only a fraction of a millimetre and generally is only to be noticed by lateral inspection.

(2) The surface of the carcinomatous superficial layer is not smooth and shiny as the surface of the normal epithelium, but frequently dull and eventually wrinkled.

(3) While the normal squamous epithelium is transparent enough to allow the stroma and its vessels to shine through which gives it a reddish or blueish discoloration, the carcinomatous superficial layer is less transparent and thus appears to be of a brighter white and lighter in colour than the normal epithelium. The incipient carcinoma when clinically recognisable appears as leukoplakia.

How can the cancer not forming a leukoplakia be made clinically visible and how can it be made more easily visible when it is leukoplakic? The changes in a leukoplakia are not very conspicuous and easily apt to escape examination. My first efforts were in the direction of differentiating the normal epithelium from the carcinomatous by some vital staining. These experiences, which I tried with a great number of dyes, gave no useful results. But numerous histological examinations which I had carried out of beginning cancers and of carcinomatous layers showed a way which finally led to my goal. The normal squamous epithelium of the portio vaginalis shows in its superficial layers more or less flattened cell alveoli which consist only of thickened cell walls and eventually of shrunken, trabecular, dark nuclei. The inner part, normally occupied by the protoplasm, appears vacant in the slides, and only at the margins adherent to the thickened walls of the cells slight remnants of the shrunken protoplasm are eventually to be found. The usual stainings show these superficial cells as empty alveoli: if, however, such a slide is stained by Best's method the empty alveoli can be seen to contain great quantities of

granular glycogen, which forms an inner coating of the walls of the cells. This glycogen is a physiological part of the vaginal and cervical epithelium which under normal conditions is never missing.

By comparative histological examinations we may prove that stratified epithelium nearly always contains glycogen in its superficial layers, as long as it does not get keratinised; for example, the external skin in the embryonal development shows a phase of formation of glycogen as long as it does not get hornified. Staining showed that the glycogen disappears with the change of normal epithelium into a carcinomatous superficial layer, just as it does in keratinisation. As the transition of normal epithelium into carcinoma occurs suddenly and without intermediate stages the glycogen is also seen to disappear suddenly in the areas where the normal epithelium changes into carcinomatous epithelium (Fig. 3). The proof of the presence or the absence of glycogen may serve to make the borderline between normal epithelium and cancer apparent. There are two methods of demonstrating glycogen by staining:—

(1) *Best's alkaline carmine method.*—This is very good for sections and gives clear, fine histological pictures, but it is not in the least suitable for the living tissues and for the demonstration of the borderline between carcinomatous and normal epithelium on the living, because the carmine solution is too alkaline, the amount of ammonia causing oedema and consequent necrosis of the tissues.

(2) *The aqueous iodine test.*—This method is not specially suitable for histological purposes, but is very satisfactory for demonstration in vivo and on the living patient, the aqueous solution of iodine causing no injury of any kind. The stratified squamous epithelium of the cervix and vagina is stained dark brown, while the carcinomatous epithelium and the superficial cancerous layer remain quite white and unstained. If the cervix is washed

FIG. 3.—Cervical epithelium, stained by Best's method. (a) Normal: showing glycogen granules in upper part. (b) Malignant: complete absence of granules.

with the solution the normal epithelium will become stained dark brown in 20–30 seconds while the carcinomatous epithelium will remain white. In this way there is a sharp distinction and the cancerous epithelium is distinctly marked off in an area which appeared covered with normally coloured epithelium. Of course, only a watery solution must be used for this demonstration; if an alcohol is used the differentiation is visible only in the first few seconds and disappears rapidly, when the entire epithelium, carcinomatous as well as normal, is

stained a homogeneous dark brown. I found the following combination the optimal solution, the so-called Gram's solution: pure iodine, 1 part; potassium iodide, 2 parts; water, 300 parts. This weak concentration has the disadvantage that the staining will take longer, 30-60 seconds instead of 10, but this is of no importance. Yet it has the great advantage of staining much more distinctly and giving much finer differentiations. This diluted solution is also much cheaper than a concentrated one.

It must be stated again that this iodine test is not specific for carcinoma but marks off only the areas which contain no glycogen. Glycogen is always absent in cancer but not only in cancer. It is also absent—

(1) In carcinomatous transformation of epithelium. These early cancers of the surface are to be distinguished by their sharp and map-like demarcation. With the central part of their periphery they touch the external os—i.e., the borderline between the columnar epithelium of the cervical canal and the squamous epithelium of the portio uteri (Fig. 4).

(2) In hyperkeratosis of the squamous epithelium of the cervix. This occurs in syphilis. These luetic leukoplakias were first described in the mucous membrane of the mouth by Schwimmer. Apparently they are not uncommon in the oral cavity but are doubtlessly very rare in the cervix. In 15 years I could find only 4 cases that showed luetic hyperkeratosis of the cervical epithelium; of these, 2 cases were clinically not very distinct. The clinical diagnosis of such luetic leukoplakias is therefore not of great importance. There was an interesting case of a woman whose uterus was extirpated for fibroids. At the histological examination I found a spot with genuine hornification. The patient denied any luetic infection and having no prolapse a Wassermann examination was made. It was positive and after six months anti-syphilitic treatment the Wassermann reaction became negative.

(3) Keratinisation developing in prolapse may also cause the glycogen to disappear. This generally grows from multiple foci, but several more or less cornified spots may become confluent. The iodine staining gives a picture of white and brownish spots upon a dark background, often joining like clouds and often ill-defined.

(4) When the superficial layers of glycogen containing epithelium have been rubbed off by inflammation, by maceration, or by the examining finger or speculum. These traumatic desquamations are easy to diagnose, being sharply defined and somewhat deepened areas.

Thus we have different possibilities which cause the epithelium of the surface to remain white. A histological examination of the suspicious spot is therefore absolutely necessary. The positive or negative diagnosis of carcinoma is far too important not to require the complete security only to be obtained by histological examination. That is why I always refuse to make any diagnosis upon the mere iodine painting and always make a point of having the suspicious area histologically examined. This examination is restricted to the epithelium without losing any of its value, for in these early cases the question is whether the epithelium is carcinomatous or normal, and the positive or negative diagnosis is to be made from the part of the superficial layer that remained white. For this purpose it is quite sufficient to scrape off the superficial epithelium with a sharp spoon; sometimes it is easier to lift the epithelium with a spoon and then to get hold of it with a tissue forceps.

For fixation it proved advantageous not to use watery formaldehyde, but to use the combination recommended by Carnoy—alcohol abs. 60 parts, chloroform 30 parts, glacial acetic acid 10 parts. This solution has the advantage of fixing the tissue quickly and it does not contain water.

In the slide of the scrapings a diagnosis of cancer

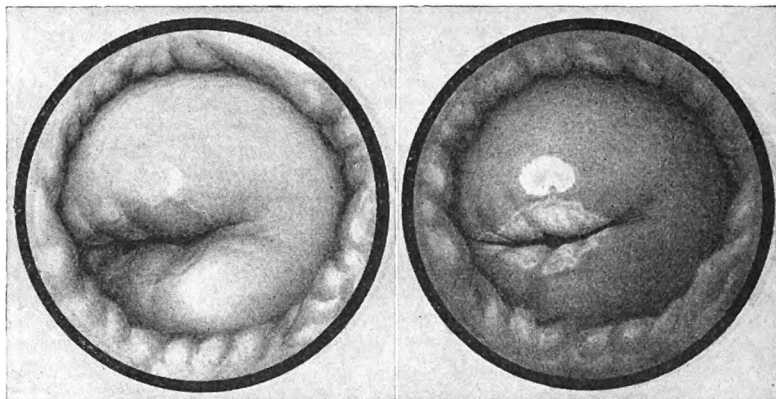

FIG. 4.—The iodine test. Appearance of carcinoma of the cervix (left) before and (right) after application of iodine.

or no cancer has to be made; it must be based almost exclusively upon the characteristic cell which are polymorphous and atypical, and upon the carcinomatous change and differentiation of epithelium. There is no uniform rule to follow for this diagnosis; certainly it is not as easy as the diagnosis of, say, tuberculosis or malaria. It requires experience and practice and must be learned systematically; but it is certain that no one should take the responsibility of giving a diagnosis in a doubtful case without a thorough study of the histology of each carcinoma and without profound practice.

The method of the iodine painting is easily carried out in an out-patient department, requiring no special training for the doctor and causing the patient no pain. It does not need complicated apparatus nor does it take long to do. The procedure of introducing a speculum, painting with iodine, wiping it off, and examining can be carried out within 3-4 minutes; the cost of the iodine solution is negligible. I must point out that the staining will vanish after a few minutes by evaporation and resorption of iodine. Ill-effects in patients hypersensitive to iodine were never seen.

A further field of application for the iodine painting is in the revelation of cancerous marginal zones of progressed carcinomata. These marginal zones frequently are clinically invisible and consequently are hidden from the eye of the operator. It will happen that the doctor believes he has operated the cancer in the healthy tissue while in reality the operation was carried out within the marginal cancerous superficial layer and part of it was left behind; then, of course, a recurrence will follow. This can be avoided if the operator will paint the border zone between cancer and normal epithelium with iodine. If there is a white zone the operation must not be confined to the white zone but carried into the brown zone. The operation is only radical if the line of incision is within the brown parts.

#### RESULTS

The method can be applied without difficulty, but it has its full value only when carried out on

as many patients as possible. I have seen patients 25-26 years of age with smooth, homogeneous shining white portios that seemed altogether above suspicion to the eye of the clinician, but when painted with iodine they showed a small white speck, which when scraped off proved to be a carcinoma. No case should be considered absolutely and even should a portio appear clinically quite harmless the iodine staining may reveal an incipient cancer. The gynaecologist who paints only the suspicious cases is sure to miss the most important stage—the smallest, clinically latent cancer. The consequence is that the more general the examination by iodine painting the smaller will be the proportion of positive cases. In my last series, out of every 100 women examined in our out-patient department about 20 showed suspicious areas, and of these 20 only 1 or 2 proved to be cancers in the histological examination of the scrapings. But even if only 1 per cent. of the examined women give a positive diagnosis the result is still exceedingly satisfactory, for we must not forget that a carcinoma when detected and treated at that early stage gives nearly 100 per cent. security for definite permanent healing.

The iodine test has been tried by many gynaecologists; in England by Beattie, in France by Forgue and Pouliot, in Italy by Boschetti, Casati, and Cuizza, and in America by Graves, Norris, Smith and Pemberton, Stearns, &c. The last published negative results, but immediately afterwards he told me by letter that by iodine painting he had succeeded in revealing a cancer of the cervix that was diagnosed by the pathological institute of the University of Nebraska as the youngest carcinoma ever seen there. In America efforts are being made to examine patients two or three times a year by iodine painting. If the test is negative there is the certainty that there is no carcinoma in the area of the squamous epithelium. Should a cancer develop before the next examination the cancer if revealed at that next control examination will be so small that it will fully ensure definite permanent healing. If it were possible by this procedure to examine systematically at few months' intervals as large a number of women as possible, we might hope to get in this way a predominant proportion of cervical cancers for treatment at such stages as would fully guarantee permanent healing. Thus it would be possible greatly to lower the mortality of this disease.

BRISTOL'S HOSPITALS.—The seven voluntary hospitals of Bristol need at least £250,000 for modernisation, equipment, and extension. A house-to-house collection is being taken to help to raise this sum.

## OBSERVATIONS ON CASTLE'S INTRINSIC FACTOR IN PERNICIOUS ANÆMIA

By C. C. UNGLEY, M.D., Durh., M.R.C.P. Lond.

ASSISTANT PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY,  
NEWCASTLE-UPON-TYNE; LEVERHULME RESEARCH SCHOLAR OF  
THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; AND

ROBERT MOFFETT  
TECHNICAL ASSISTANT

THE classical experiments of Castle and his fellow workers<sup>1,7</sup> have shown that material effective for blood regeneration in pernicious anæmia arises from the interaction of an intrinsic (gastric) factor present in normal gastric juice and an extrinsic (food) factor. Literature up to November, 1935, is reviewed elsewhere.<sup>8</sup>

In November, 1935, at the suggestion of Dr. H. D. Dakin, we began experiments with the object of determining whether or not the hæmopoietic factor in gastric juice and gastric mucosa might be pepsinogen. The intrinsic factor was known not to be pepsin,<sup>4</sup> but this did not exclude pepsinogen: the precursor of an enzyme may have an action entirely different from that of the enzyme itself. Castle<sup>7</sup> obtained no positive result with gastric juice and meat muscle unless the mixture was neutralised before administration. Dakin<sup>9</sup> suggested as a possible explanation of this that beef muscle by adsorbing pepsinogen protected it from destruction even at pH 3, but that if the acidity persisted all pepsinogen was converted to pepsin. On this theory, the hæmopoietic inactivity of fundus \* mucosa as reported by Meulengracht<sup>10</sup> was explained as being due to the destruction of pepsinogen in the presence of hydrochloric acid from the fundus glands. There were certain facts which could not well be explained on this hypothesis, such as the presence of intrinsic factor in desiccated pylorus<sup>10</sup> which was free or almost free from peptic activity and presumably from pepsinogen. †

The first step in the present work was to investigate the pepsinogen theory. For this purpose the fundus mucosa of pigs' stomachs was extracted under alkaline conditions designed to preserve pepsinogen. Subsequently the same method was applied to pylorus mucosa with results to be described. Later (February, 1936) the trend of investigations was modified by Greenspon's suggestion<sup>11</sup> that the gastric anti-pernicious anæmia factor was a hormone effective alone if protected from the action of pepsin. He described 2 cases of pernicious anæmia which responded to depepsinised desiccated gastric mucosa fed without the addition of beef. The feeding of cold neutralised normal gastric juice, collected and administered under conditions designed to prevent peptic activity, was effective in one case of pernicious anæmia, without the addition of beef or other source of "extrinsic factor." On the basis of these findings Greenspon questioned the existence of an "extrinsic factor" as conceived by Castle, and suggested that in Castle's basic experiments beef, by adsorbing pepsin, merely protected the gastric hæmopoietic factor from destruction. With regard to autolysed yeast, as used in Castle's later experiments,<sup>6</sup> Greenspon suggests that it "contains ele-

\* English terminology, corpus region.

† The method used<sup>10</sup> involved adding an amount of edestin solution at pH 1.5 almost certainly sufficient to activate pepsinogen had it been present.

ments that are capable of stimulating the cells that elaborate the gastric anti-anæmic agent, or that these elements furnish material for the synthesis of the latter."

In view of past observations,<sup>12</sup> however, it seemed to us unlikely that the rôle of autolysed yeast could be entirely explained in this way, nor did it seem probable that adsorption of pepsin would account for its effect. Subsequent experiments were therefore modified to test the validity of Greenspon's theories.

#### THE INQUIRY AND ITS RESULTS

Fourteen fully investigated cases of Addisonian pernicious anæmia in relapse, all showing a histamine-refractory achlorhydria, were utilised for this work. For brevity, clinical and biochemical findings other than those required for the present analysis are omitted. No case utilised showed evidence of spontaneous remission during a control period of 10 days. A shorter period was allowed in cases where the erythrocyte count fell rapidly. In Case 9 a small reticulocytosis without rise of red blood-cells occurred during the control period, but the counts remained stationary during the 10 days preceding the commencement of treatment.

The patients received a meat-free diet throughout. Fundus and pylorus mucosa extracts were fed as a drink without flavouring. When Marmite was used it was given either in sandwiches or as a drink together with white bread and butter. When the object was to prevent their interaction stomach extracts or gastric juice were given four hours before breakfast and the marmite at tea-time. When interaction was desired, the stomach preparation and the marmite were fed at the same time (3.30 P.M.). Liquid yeast extracts, such as a 65 per cent. alcohol-soluble fraction of unflavoured, unsalted marmite (A.E.M.), were mixed with the stomach extract immediately before administration. The results are summarised in the accompanying Table.

*Fundus Mucosa Extract.*—The fundus area<sup>10</sup> was excised from the stomach of freshly killed pigs and the mucosa dissected from the muscle. The mucosa, rich in peptic and oxyntic glands,† was minced and extracted under conditions designed to preserve pepsinogen and prevent activation of pepsin.<sup>13</sup> The materials were ground together in a mortar in the proportion of one part mucosa, one-tenth part kieselguhr, and four parts tenth-normal sodium bicarbonate solution. After filtration through nainsook, the fundus mucosa extract (pH 8 to 8.5) was kept at 0° to 2° C. until administration. The peptic activity, after acidification, was usually 32 units by Fuld's edestin method (pH before addition of edestin 1.5 approx.). 150 c.cm. of this extract, derived from 40 g. of fundus mucosa, was fed simultaneously with marmite to 3 patients. The results were negative but inconclusive in Case 1, and definitely negative in Cases 2 and 14. In a further patient (Case (5a)), a concentrate of 2.6 per cent. pure pepsinogen in glycerin 80 to 90 per cent. (kindly supplied by Dr. R. M. Herriott of Princeton, U.S.A.) was given daily in doses of 1.5 c.cm. (diluted to 30 c.cm.) along with marmite. Except for a slight reticulocytosis the result was negative.

*Pylorus Mucosa Extract.*—The method of extraction described for fundus was next applied to pylorus mucosa. Part of the pyloric end of pigs' stomachs was excised<sup>10</sup> and the mucosa† dissected off. From

each pig's stomach (average weight 700 g.) the average yield was 56 g. of fundus mucosa and 35 g. of pylorus mucosa. As with fundus extract, the pH was 8.0 to 8.5, and 150 c.cm., derived from 40 g. was given daily. No peptic activity could be detected by the method mentioned above. To overcome difficulties associated with bacterial infection later batches of fundus and pylorus extract were filtered through a cotton-wool plug and rendered 0.3 per cent. in respect to trikresol.

The pylorus mucosa extract was given simultaneously with a source of extrinsic factor (marmite 12 g. or 65 per cent. alcohol-soluble fraction of unflavoured, unsalted marmite (A.E.M., 12 c.cm.)) in 8 cases. In one instance (Case 4) the experiment was abandoned after two days because of gastro-enteritis. In Case 12 treatment was discontinued after seven days because of gastro-enteritis and fever lasting from the sixth to ninth day, but there was nevertheless a moderate reticulocytosis and a satisfactory rise of red blood-cells, both delayed by the infection.

Five patients (Cases 3, 5 (b), 9 (b), 10 (b), and 11 (b)) received for 10 days pylorus extract together with marmite 12 g. Although the reticulocyte responses were small, subjective improvement was rapid and the rate of increase of red blood-cells satisfactory. Despite a high average initial red blood-cell count (2.02 millions per c.mm.) these 5 cases showed an average increase of 0.63 million in 10 days, and 1.20 millions in 20 days. This compares well with the increases of 0.46 and 1.25 millions in 10- and 20-day periods (from an initial level of 1.35 millions), which followed the feeding of extract derived from rather more than 250 g. of liver daily (see Ungley, Davidson, and Wayne,<sup>15</sup> Table III.c, calculated from data reported by Minot, Cohn, Murphy, and Lawson<sup>16</sup>). The average increase in 20 days (derived from figures available in 4 out of the 5 cases) is particularly satisfactory, since potent material was administered only during the first half of that period.

In Case 13 there was a less satisfactory response, which may or may not have been due to the use of A.E.M. 12 c.cm. instead of marmite 12 g., or to the fact that the preparation of the stomach extract had been modified (further filtration, addition of trikresol to 0.3 per cent.). During the ensuing 10 days the same materials incubated for three hours at 37.5° C. immediately prior to administration produced a secondary reticulocytosis but no other evidence to suggest that such incubation had led to increased potency.

The hæmopoietic effectiveness of pylorus mucosa is in contrast with fundus mucosa's inactivity in this respect, and accords with Meulengracht's findings: pepsin (and pepsinogen) and the anti-anæmic factor are disassociated physiologically and anatomically in the stomach.<sup>10</sup>

*Inactivation of Pepsin with Alkali.*—Peptic activity is destroyed at pH 9.8 and at Dr. Dakin's suggestion this method was used in the present investigation to "depepsinise" normal gastric juice and stomach extracts. The gastric juice was collected from normal students during a period one hour after the administration of histamine 0.5 mg. Immediately after withdrawal each sample of juice was placed in a vessel surrounded by ice, and normal caustic soda added from a burette, with rapid stirring, until the mixture was just alkaline to litmus. The day's yield of juice was then adjusted to pH 9.8 by the addition of normal NaOH, the pH being measured by electric potentiometer. Material treated in this way showed

†Characteristics of fundus and pylorus mucosa confirmed microscopically.

## SUMMARY OF RESULTS

## EXPLANATORY NOTES

*Days* refers to days after the commencement of treatment.  
*Reticulocytes*.—Except in the case of injected liver fractions where figures for intravenous liver therapy (i.v.) are given, the "expected maxima" are those calculated by Bethell and Goldhamer<sup>14</sup> for desiccated stomach. In assessing the effect of therapy account must be taken of the fact that "secondary" reticulocyte peaks (given in parentheses) do not usually reach the levels expected from a "primary" response. Where the summit of the response was a "plateau" rather than a "peak" (Case 10 (b)) counts closely approximating to the maximum are given.

*Red blood-cell increases* attributable to experimental material (i.e., material other than liver extract or desiccated stomach) are printed in heavy type. When the rise of red blood-cells

at 10 days was of doubtful significance, the ineffectiveness of the material was sometimes made evident by the absence of any further increase at the 15th day (given in parentheses where this point occurred 5 days after the commencement of the second experimental period). When effective material was fed the red blood-cell count had not usually risen by the 5th day, but on the other hand the increase, evident at the 10th day, usually continued for 15, 20, or even 30 days, despite the absence of further treatment.

*Abbreviations*.—R.B.C. = red blood-cells. Retic. = reticulocyte. Ext. = extract. Conc. = concentrate. G.J. = gastric juice. V. & D. = vomiting and diarrhoea. S.C.D. = subacute combined degeneration. Expt. = experiment. Sl. = slight. R.R. = reticulocyte response.

\* Count on 13th day. † Response delayed by infection.

no peptic activity as measured after acidification (see fundus extract). In Case 7, with a red blood-cell level of 1.31 millions per c.mm., 100 c.cm. of such juice was given on an empty stomach at 5.30 A.M. with no food for four hours. Marmite 12 g. was given at 3.30 P.M. either in sandwiches or as a drink. There was a slight reticulocytosis (4.7 per cent.) but the patient became worse and the red blood-cells fell to 0.98 million. At the end of 10 days the depepsinised gastric juice was given simultaneously

with the marmite at 3.30 P.M. so that interaction could take place within the body. Reticulocytes rose to 15.8 per cent. on the eighth day and the red blood-cells rose from 0.98 to 1.29 millions per c.mm. on the tenth day, with subjective improvement and cessation of sore tongue. The subsequent injection of liver fractions led to further reticulocytosis, and a satisfactory rise of red blood-cells. The sub-maximal response to gastric juice and marmite even when given together suggests either (1) that the dose

of gastric juice was too small or (2) that pH 9·8 impaired hæmopoietic activity or (3) that the patient was relatively resistant to oral therapy. Besides indicating the necessity for interaction with extrinsic factor, this case shows that subjection to pH 9·8 for 30 minutes, which will inactivate pepsin and pepsinogen, is not sufficient to abolish hæmopoietic activity. This result is confirmed in Case 12 with red blood-cells 1·48 millions: pylorus extract subjected to pH 9·8 fed together with marmite led to a reticulocyte response of 15 per cent. and a satisfactory rise of red blood-cells (both delayed by inter-current infection). The negative or slight effect obtained in Case 6 (a) is not relevant since no source of extrinsic factor was provided in this instance; neither is the negative result obtained with fundus extract subjected to pH 9·8 (Case 8) since fundus is in any case without hæmopoietic effect (see above).

*Necessity for Interaction with Extrinsic Factor.*—The relative or absolute ineffectiveness of sources of intrinsic factor fed without or separate from material containing extrinsic factor is indicated by the negative or inconclusive results obtained with depepsinised gastric juice (Case 7(a), already described), pylorus mucosa (Case 6(b)), and pepsin-free extracts of pylorus mucosa (Cases 9(a), 10(a), 11(a)§). In Case 6(b) and (c), with an initial red blood-cell count of 3·07 millions per c.mm., the feeding of pylorus mucosa alone was associated with an increase in red blood-cells of only 0·29 million per c.mm. in 15 days, whereas simultaneous administration with marmite led to a rise of 0·86 million per c.mm. in 15 days. In Case 9, with red blood-cells 1·62 millions per c.mm., there was no response to pylorus extract and marmite fed separately in a manner designed to prevent their interaction. When, for the next 10 days, these materials were given simultaneously, there was a reticulocytosis of 5·7 per cent. on the seventh day and a gain in red blood-cells of 0·36, 0·45, 0·51, and 0·75 million per c.mm. in 10, 15, 20, and 30 days respectively without further treatment. In Case 10, with red blood-cells 1·97 millions per c.mm., the administration of pylorus extract and marmite given separately to prevent their interaction was accompanied by a reticulocytosis of 8·1 per cent. on the seventh day, but the red blood-cell count fell to 1·59 millions per c.mm. When fed simultaneously for the next 10 days these materials produced a prolonged secondary reticulocytosis reaching 8·1, 7·9, 8·2, 8·9, 10·2, and 8·9 per cent. on the fifth to tenth days respectively, and without further treatment the red blood-cells increased by 0·55, 0·80, 1·07, and 1·33 millions per c.mm. in 10, 15, 20, and 30 days.

In the case of a 65 per cent. alcohol-soluble fraction of autolysed yeast, which was effective as a source of extrinsic factor (Case 13), no diminution of peptic activity could be detected after this extract was incubated in contact with gastric juice or fundus mucosa extract. Altogether it is evident that the rôle of extrinsic factor in autolysed yeast cannot be explained solely, if at all, by adsorption of pepsin. Moreover, it is unlikely that its rôle is to stimulate the cells that elaborate the gastric anti-anæmic agent,<sup>11</sup> otherwise one would have expected much the same effect in Cases 7, 9, and 10 whether the two materials (a) depepsinised gastric juice or pylorus extract and (b) marmite were given at widely separate intervals or simultaneously.

§ In Case 11 the yeast extract given in the first period (a) was clearly ineffective as a source of extrinsic factor, since no significant response occurred until marmite was substituted.

## SUMMARY AND CONCLUSIONS

(1) Experimental data obtained in 14 cases of pernicious anæmia are recorded.

(2) A watery extract of fundus mucosa of pigs' stomachs (pH 8·0 to 8·5), containing pepsinogen but prepared in a manner designed to prevent activation of pepsin, when administered together with a source of extrinsic factor gave negative results in 2 cases and a negative but inconclusive result in a third.

(3) A concentrate of pure pepsinogen in glycerin was likewise ineffective as a source of intrinsic factor in 1 case.

(4) A watery extract (pH 8·0 to 8·5) of pylorus mucosa, prepared as for fundus, when administered in amounts derived from 40 grammes of mucosa, together with a source of extrinsic factor, was effective in 6 cases.

(5) The intrinsic factor was not destroyed by a degree of alkalinity (pH 9·8 for 30 minutes) which will inactivate pepsin and pepsinogen (2 cases).

(6) Pepsinogen and the anti-anæmic factor are dissociated physiologically and anatomically in the stomach (cf. Meulengracht<sup>10</sup>).

(7) Depepsinised gastric juice and pepsin-free extracts of pylorus mucosa had little or no hæmopoietic effect when given perorally unless interaction with a source of extrinsic factor (e.g., autolysed yeast) was allowed.

(8) In these circumstances the rôle of the extrinsic factor could not be attributed to adsorption of pepsin, since none was present.

(9) The effect of intrinsic and extrinsic factors given simultaneously is considerably greater than the sum of effects, if any, produced by the two factors given under conditions designed to prevent their interaction.

(10) This interaction of intrinsic and extrinsic factor does not require incubation outside the body.

(11) Since autolysed yeast in the dose employed (12 g. daily) required interaction with normal gastric juice or pylorus extract to render it effective for blood regeneration, it probably acts by virtue of its content of extrinsic factor and not because "it contains elements that are capable of stimulating the cells that elaborate the gastric anti-anæmic agent or because these elements furnish material for the synthesis of the latter."<sup>11</sup>

(12) None of the findings in this investigation was incompatible with Castle's basic hypothesis.

## MODERN TECHNIQUE IN BRONCHOGRAPHY

By G. S. ERWIN, M.B. N.Z.

RESIDENT MEDICAL OFFICER, BROMPTON CHEST HOSPITAL,  
LONDON

WITH the increasing use of a variety of opaque media to delineate the bronchial tree, it has become necessary to employ a word to denote the process itself as apart from any particular medium, and to this end the term "bronchography" has been coined. It seems, therefore, indefensible to continue the use of the trade name "Lipiodol" as a synonym, for although this French product is the one chiefly employed for the purpose in this country, it is by no means the only one. Others are Neo-hydriol, an English compound of similar constitution, and Iodipin, which comes from Germany.

Iodism of varying degrees from a mild rash to a severe and even fatal reaction<sup>1</sup> has in a small proportion of cases followed the introduction of these iodine-containing media, so that for patients who have previously shown iodine sensitivity it is advisable to use a brominised oil such as Brominol or Bromipin. These media are less opaque to X rays so that the resultant bronchograms are not as a rule well defined.

A retrospective study of the earlier bronchograms in which we were pleased to see a little lipiodol in some bronchi, even if not the diseased ones, takes us through the stages of evolution to present-day complete bronchography and the reasons which have engendered it. In the first place, a radiologist who is faced with a film showing incomplete filling of the bronchi, but in which such bronchi as are outlined appear to be normal, can only report to that effect; he cannot give a satisfactory opinion on the remainder, so that disease thereof has not necessarily been excluded. Secondly, the increasing safety and success of lobectomy and pneumonectomy, particularly for bronchiectasis, have made it essential that the exact number of lobes involved in the disease process should be known beforehand in order that the risks of operation and the chances of complete or partial cure may the more surely be assessed. An ancillary consideration is the follow-up of these cases, in which a complete bronchography before and after the operation is imperative. Even in the medical treatment of bronchiectasis the recent successful introduction of continuous postural drainage<sup>2</sup> has rendered a more exact localisation of the disease desirable, so that we may decide the correct position or positions to be adopted in any particular case. Again the follow-up of serious medical treatment demands complete outlining of the bronchi.

### ANATOMICAL CONSIDERATIONS

The methods to be described here of studying the bronchial tree have been evolved from a consideration of its anatomy as described recently by Nelson,<sup>2</sup> a recapitulation of the main features of which will help in the understanding of the technique involved.

The lung is considered fundamentally to consist of four lobes—upper, middle, lower, and dorsal. On the right side the lower and dorsal elements are fused to form what is known as the lower lobe, the other two remaining separate, whilst on the left side the upper lobe consists of upper and middle elements combined, and the lower represents, as on the right, lower and dorsal elements. There is a separate main bronchus to each of the four elements, and it is

necessary in complete bronchography to fill all of these as well as their more important branches. The upper lobe bronchus on the right runs laterally from the lateral wall of the main bronchus for about 1 cm. before dividing into its three components, apical, pectoral, and axillary, terms which are self-explanatory. On the left side the upper and middle lobe bronchi spring from a common stem which arises from the antero-lateral wall of the main bronchus. The upper lobe components are similar to those on the right except that the apical and axillary branches are fused in the earlier part of their course. The middle lobe bronchus on the right springs from the main bronchus and runs forwards, upwards, and downwards. On the left it pursues a similar course after taking origin from its stem in common with the upper lobe bronchus. The dorsal branches are almost identical on the two sides, springing from the main descending bronchus, which then proceeds as the lower lobe bronchus for a short distance before dividing into its three basal branches, anterior, axillary, and posterior.

### TECHNIQUE

From a study of these anatomical points it will be seen that an antero-posterior view of the chest is quite insufficient for a satisfactory review of the bronchial tree after injection of an opaque medium, and that a lateral view will be required. If, however, both sides have been filled indiscriminately, the overlap in the lateral view will be at best a poor palimpsest, at worst a confused tangle of bronchi impossible to unravel. Stereoscopic radiograms will overcome this disadvantage, but, as few hospitals in England are equipped with apparatus even to take stereoscopic bronchograms, still less to view them in ward and theatre, it has been incumbent on us to devise a technique which will render the procedure superfluous.

It is found in practice that the complete outlining of each lung separately with corresponding antero-posterior and lateral views is almost always satisfactory, the only disadvantage being that two sessions are necessary. This is no hindrance in an in-patient as an interval of two days is usually sufficient to clear the treated lung of the greater part of the opaque substance so that it does not obscure the lateral view of the other side, but it does constitute a grave disadvantage in out-patients who are working and unable to come up more than once, and in nervous patients who may refuse further to submit themselves after their first ordeal. For these patients a one-stage compromise of great usefulness has been devised—namely, the filling of the diseased or most diseased side completely, the taking of an antero-posterior and a lateral film immediately, followed by filling of the other side partially or completely as circumstances may dictate, and a further antero-posterior film. In practice it is usually sufficient to fill the lower and middle lobes of the less affected side.

The lower lobe being the one most frequently involved in bronchiectasis, and the most easily filled, indeed being not infrequently the only one filled by the older methods, we proceed to outline its bronchi first. With the patient in a semi-recumbent position and slightly turned to the side which it is proposed to fill, about 10 c.cm. of the oil is introduced and a few seconds allowed for it to run down to the smaller bronchi of the lower and dorsal lobes. The patient then sits up, still leaning to the same side and also a little forward;

about 5 c.cm. of the medium is introduced and it will be found that this runs directly into the middle lobe. Again the patient is returned to the semi-recumbent position, but this time lying completely on the side that is being filled, and the remaining few c.cm. injected. This last portion runs down the lateral wall of the trachea and main bronchus and enters the orifice of the upper lobe bronchus by gravity, but, as the left upper lobe bronchus arises rather more anteriorly, it is advisable to have the patient slightly inclined to the prone position to make more certain of it when filling this side. The oil having been injected and having already commenced to fill the axillary part of the upper lobe, the apical and pectoral divisions are filled most reliably by turning the patient almost completely on his face and tilting the head down or the feet up. The filling of the one side is then complete and films are taken as described.

#### METHODS OF INTRODUCING OPAQUE MEDIA

It is outside the scope of this paper to enter into a full discussion on the vexed question as to which is the best method of introducing iodised oil into the bronchi. I prefer the usual cricothyroid route, which possesses only one disadvantage in connexion with the methods described—namely, that it is necessary to remove the needle during the filling of the upper lobe, thus necessitating its reinsertion if it is desired to fill the other side at the same session. In practice this is of no importance as the area is already anaesthetised and no added discomfort is caused to the patient. The nasal catheter method is perhaps preferable in some ways, not having this disadvantage, but on the other hand, to obtain full benefit from the procedure, it is advisable to watch the progress of the opaque oil under the screen and yet to be able to take a radiogram at suitable intervals, a feat which is not possible in many hospitals owing

to the disposition of the X ray plant. The trans-nasal method recently described by Forestier and Leroux<sup>3</sup> is much simpler but less certain, though good results in filling the upper lobe are claimed. The other method in common use, transglottic injection with a laryngeal syringe, is the most difficult for complete bronchography because of the dexterity required for injecting oil when the patient is in the recumbent lateral position.

Whatever the method of injecting the opaque medium employed however—and no doubt each will prefer that to which he is accustomed—the positions adopted for filling individual lobes will be the same, as should by now be evident. The superiority of the technique described lies, not in its absolute certainty, for no method can have this, but in the principle that by its calculated completeness it reduces error to a minimum. It will readily be understood that the neurotic patient and the patient who coughs abundantly will defeat even the most painstaking efforts, and that a dose of opium preceding the manoeuvres is still our best antidote for both. Care must be taken, too, that the oil is at a suitable temperature, for if too hot it will run rapidly into the alveoli and obscure the bronchograms, and if too cold it will not reach the lesser bronchi. Children under a general anaesthetic present constant difficulty in posturing, but with a little practice a fair attempt at the one-stage technique may be made; the middle lobe is sometimes filled more easily in the prone position, the upright posture being difficult to accomplish.

My thanks are due to Mr. H. P. Nelson and Dr. Lee Lander for some suggestions about the one-stage technique described.

## CLINICAL AND LABORATORY NOTES

### A SIMPLE TEST FOR LATENT JAUNDICE

By H. S. BRODRIBB, B.M. Oxon.

LATE HOUSE PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL; AND

E. R. CULLINAN, M.D., F.R.C.P. Lond.

ASSISTANT PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL;  
PHYSICIAN, WOOLWICH MEMORIAL HOSPITAL

IN the diagnosis of suspected hepatic or biliary disease it is important to know whether the bilirubin in the blood is increased. Unfortunately, this fact can seldom be recognised by the observation of jaundice in the skin or sclerotics until the concentration of bilirubin has risen from the normal (between 0.1 and 0.4 mg. per cent.) to 2 mg. per cent. (4 units of van den Bergh) or over. The exact concentration can, of course, be determined by the van den Bergh reaction, but this is often impracticable at the bedside. O. Klein<sup>1</sup> (1931) showed that wheals produced in the skin of jaundiced patients by the intradermal injection of minute quantities of histamine became more deeply yellow than the surrounding skin. Further, he found that a yellow colour could be seen in histamine wheals when the concentration of bilirubin in the blood, though raised, was insufficient to produce jaundice in the rest of the skin or in the sclerotics. He attributed this phenomenon to the abnormal permeability of the capillaries for bile-pigment caused

by the histamine, allowing the pigment to escape and concentrate in the wheal.

We have carried out this test on a number of cases and have found it to be a simple and reliable method of determining qualitatively the presence of latent jaundice. It is useful particularly as a clinical test, even if only as a preliminary to more complicated quantitative estimations. In cases of obstruction of the biliary tract or of damage to the liver cells the test is constantly positive when the concentration of bilirubin in the blood has risen above 0.5 mg. per cent. (1 unit of van den Bergh). In cases of hæmolytic jaundice the test is not positive until the concentration of bilirubin is rather greater (between 1.1 and 1.4 mg. per cent.). This conforms with the clinical observation that in cases of hæmolytic jaundice the yellow colour is not seen in the skin or sclerotics until the concentration of bilirubin has reached a higher figure than in cases of obstructive jaundice.

#### TECHNIQUE

The patient is placed in good daylight. Direct sunlight and artificial light are unsatisfactory. A small area of skin free, if possible, from sunburn and freckles is cleaned with spirit. The most suitable site is usually on the upper arm or on the back. One minim of a sterile solution containing 0.1 mg. of histamine is injected *intradermally* into this area by means of a fine hypodermic or special intradermal needle. It is essential that the injection should be made intradermally and if it is done correctly a small

<sup>1</sup> Klin. Woch., 1931, x., 2032.

white circumscribed bleb is produced in the skin. The dose of histamine should not exceed 0.1 mg. as larger amounts may produce an unpleasant reaction. The preparation used by us was histamine acid phosphate (Burroughs, Wellcome and Co.): 0.3 mg. of this salt is equivalent to 0.1 mg. of histamine. Within about five minutes a circular wheal, surrounded by an erythematous zone, develops in the region of the injection. This may also extend in a linear fashion for a short distance along the neighbouring lymphatics. In 10 to 20 minutes the wheal reaches its maximum size; any moisture on the surface of the wheal should be wiped away before it is examined.

If the test is positive the wheal is definitely yellow when compared with the normal skin outside the erythematous zone. This yellow colour is much enhanced by the pressure of a glass slide or by placing the two thumbs on each side of the wheal and stretching it between them, the observation being made at arms length. If there is any doubt as to whether the wheal is yellow or not, the test is regarded as negative. When the patient is already jaundiced, the colour of the wheal will be a deeper yellow than that of the adjacent skin, but in such cases the test is obviously unnecessary.<sup>2</sup>

Table Showing Results of the Test

	No. of cases.	Bilirubin.		Result.
		Mg. per cent.	Indirect Van den Bergh units.	
OBSTRUCTIVE AND HEPATOGENOUS GROUP —i.e., cholelithiasis, catarrhal jaundice, toxic jaundice, &c.	20	Over 2.5	Over 5.0	Pos.
	13	2.5 to 0.8	5.0 to 1.6	Pos.
	2	0.75	1.5	Pos.
	3	0.7	1.4	Pos.
	3	0.6	1.2	Pos.
	1	0.55	1.1	Pos.
	2	0.5	1.0	Pos.
	2	0.5	1.0	Neg.
	1	0.45	0.9	Neg.
	1	0.4	0.8	Neg.
HÆMOLYTIC GROUP —i.e., acholuric jaundice, pernicious anæmia, &c.	6	Over 2.5	Over 5.0	Pos.
	5	2.5 to 1.8	5.0 to 3.6	Pos.
	2	1.6	3.2	Pos.
	1	1.5	3.0	Pos.
	2	1.4	2.8	Pos.
	2	1.1	2.2	Neg.
	2	1.0	2.0	Neg.
	3	0.8	1.6	Neg.
3	0.7 to 0.5	1.4 to 1.0	Neg.	
NORMAL CONTROLS . . . .	22	0.3 or less.	0.6 or less.	Neg.

#### RESULTS

The results of the test in a number of cases are shown in the accompanying Table. The obstructive and hepatogenous group includes such cases as cholelithiasis, catarrhal jaundice, and toxic jaundice. It will be seen that the threshold for this group is clearly defined at 0.5 mg. per cent. of serum bilirubin (1 unit indirect van den Bergh). The hæmolytic group includes such cases as acholuric jaundice and pernicious anæmia. The threshold for this group is higher and lies somewhere between 1.1 and 1.4 mg. per cent. serum bilirubin (2.2 to 2.8 units indirect van den Bergh).

We wish to thank the members of the department of chemical pathology at St. Bartholomew's Hospital for the van den Bergh estimations.

<sup>2</sup>The presence of abnormal pigments in the serum, other than bilirubin, is very uncommon; but it might be expected that the colour of such pigments would concentrate in a histamine skin wheal. We found this in a case of carotinæmia in which the concentration of bilirubin was normal.

## LITHOPÆDION IN A CENTENARIAN

BY LOH GUAN LYE, L.M.S.  
OF THE GENERAL HOSPITAL, SINGAPORE

ABOUT 212 cases of lithopædion have been reported during the last 340 years.<sup>1</sup> The length of time during which the one here reported was retained makes the present case of unusual interest.

A wizened old Chinese woman came to the Singapore General Hospital in March, 1936, complaining of abdominal pain. She said that this arose from a lump that had been present in the abdomen for 60 years but had given no symptoms until three months previously. Asked about the lump, she said that it was a baby, and she gave the following history. Menstruation commenced when she

Radiogram of lithopædion: showing skull (indicated by arrows) and vertebræ.

was 13 years of age. She was married at 18. Her first pregnancy occurred when she was 30, and a healthy female child was born after a normal labour. At 40 she had a second pregnancy which proceeded normally until near full term, when severe abdominal pains occurred. These she thought were labour pains, although very intense. A Malay woman was called in to massage the abdomen, after which all fetal movements ceased and no child was born. Pain disappeared within a month. Menstruation started again a year later, and continued regularly until the age of 70.

Examination showed a lax abdominal wall, through which a hard, nodular, tender mass could be felt. This lay near the centre of the abdomen, but was freely movable through a range allowed by the pedicle which connected it to the pelvis. No further information could be gained by examination of the stenosed vagina or of the rectum. The radiogram shows a rounded shadow in which the skull and vertebral column of a fetus are readily recognised. Her pain was evidently not severe, and after reassurance she went home.

There must remain a little doubt as to the exact age of the mother and of the fetus. The patient maintains that she did not reach the menopause until 30 years ago, when she was 70. This raises a suspicion that she may have exaggerated her age, and there is no birth certificate to confirm it. It is suggested that the radiographic shadow is the result of an ectopic pregnancy that went to term some 60 years

<sup>1</sup>Bland, P. B., Goldstein, L., and Bolton, W. W.: *Surg. Gyn., and Obst.*, 1933, lvi., 939.

ago, but its size gives little indication of the degree of maturity of the foetus which gave rise to it, for the death of a foetus is always followed by shrinkage.<sup>2</sup>

My thanks are due to Mr. J. K. Monro for permission to publish this case, and to Dr. D. Ross McPherson for the radiograph.

### TREATMENT OF PAROTID FISTULA

BY JAMES COOK, F.R.C.S. Edin.

DEPUTY MEDICAL SUPERINTENDENT AT THE BIRKENHEAD MUNICIPAL HOSTEL

FISTULÆ of the parotid gland appear to vary greatly in their tendency to spontaneous cure. This note records a somewhat chronic case of the condition and outlines what appears to be a satisfactory operation.

A boy, aged 10, was admitted to Birkenhead Municipal Hospital on Feb. 11th, 1936. Seven years before a left-sided parotid abscess had burst and had been followed by a fistula, which continued to discharge clear fluid until his admission to hospital. As the child grew up the

<sup>2</sup> Emmert, F.: *Ibid.*, 1932, lv., 646.

condition became an increasing source of annoyance, since he could not partake of a meal without soaking his neckwear; even the thought of food brought a copious flow of saliva from the external opening.

*Examination.*—The patient was fairly healthy and well built. The tonsils were slightly enlarged and there were a few carious teeth. He was given an orange to eat and there was a profuse flow of clear, limpid watery fluid from a small orifice over the left parotid gland. Between meals there was practically no discharge. The entire secretion of the gland could be made to enter the buccal cavity by external pressure over the opening. Palpation excluded a salivary calculus.

*Operation* (Feb. 17th).—The fistulous track was excised and a portion of fascia lata carefully sutured to the parotid capsule, and the wound closed. For the next few days the patient was kept under the influence of atropine with a view to diminishing the salivary secretion and so promoting healing of the wound.

Seen almost three months after the operation the wound was entirely satisfactory and there had been no recurrence of the discharge. The mental outlook of the boy had greatly improved.

I have to thank Mr. R. A. Grant for permission to publish these notes.

## MEDICAL SOCIETIES

### ROYAL SOCIETY OF MEDICINE

#### SECTION FOR THE STUDY OF DISEASE IN CHILDREN

At a meeting of this section held on May 22nd the chair was taken by the president, Sir LANCELOT BARRINGTON-WARD, and a paper on

#### Congenital Deformities of Mechanical Origin

was read by Mr. DENIS BROWNE. Present teaching, he said, varied between a flat denial and a rather deprecating acknowledgment that pressure in utero plays a part in causing deformity. With a child in the normal position in the womb, dimples were produced wherever a bony point was in contact with the uterine wall. Dimples, in his opinion, were the result of compression of tissues, followed by adhesions. They were "the footprints on the lawn" of the detective story. They were absent if there was no mechanical pressure, and increased if pressure was increased. Abnormal positions produced dimples in other parts. The feet were the most exposed to pressure of any part and if abnormally placed were curved into the talipes position with a collection of dimples over the convexity. Sometimes a further set of abnormal dimples was found near the toes of the abnormal foot corresponding with those on the normal hand—showing that the foot had taken pressure on its dorsum as the hand did always. When little toes were malpositioned because of talipes a dimple would be found just where the toe had rested on the other foot. A case of postural torticollis showed a depressed ear due to the pressure of the shoulder. One child he had seen folded up so that its feet fitted into its face; it had dorsiflexed halluces and an abnormally depressed nose, and the two fitted precisely. Acrocephalic syndactylysm might well be due to pressure of the hands against the head. Congenital dislocation of the hip (due to pressure on the knee) and congenital fracture of the tibia were best explained by mechanical pressure. Dimples were found in the latter just where they

would be if the leg had been folded and broken across the other leg. Club-hands belonged to this category: the hand was bent back owing to the absence of ulna, and dimples corresponded.

If the limbs of an adult were kept closely confined for a long time the tissues degenerated and the limbs became stiffened and atrophic. Similar changes were found in deformed babies which had been compressed in a normal position. When abnormal position was added to abnormal mechanical pressure, muscles and joints were bad and the cases were very hard to treat, although the deformity was the same to look at as in other cases. Spina bifida combined with talipes and paralysed legs was due to compression just as the foetus was starting to bend from a flat plate; the plate therefore failed to close and the limb buds grew upwards instead of forwards, so that the feet were jammed on the shoulders. (Mr. Browne showed a film demonstrating how such a child folded up with straight legs; in one case the deformed feet fitted perfectly into one another; in another they had been protected by the head.) Dimples, he continued, were sometimes found over misplaced coccyges. Amniotic bands had only been an obvious factor in one case he had seen. Spasmodic muscular pressure caused another group of deformities. A normal hip might be dislocated by such spasm. Pressure sores had been seen on new-born babies.

More arguable were the effects of increased hydraulic—as opposed to mechanical—pressure. This would affect the blood pressure, so that the tissues near the heart and sheltered by the elastic recoil of the chest received a fair amount of blood but distant parts were starved, so that arms and legs would be atrophic. In hydramnios the baby could adopt positions impossible in a normal uterus and there should be no dimples or normal pressure signs. Children were born fulfilling these conditions—for example, a child with stiff extended hips, atrophic arms and legs, and no dimples or normal mouldings. Veterinary surgery knew a congenital deformity of lambs with stiff and atrophic limbs; shepherds foretold this by the large belly of the ewe

(hydramnios). This was an interesting corroborative point.

Deformities not due to mechanical conditions included local failures of formation, ring constrictions, and congenital amputations. Sprengel's shoulder was a failure of migration, like an undescended testicle, and showed no dimples. Achondroplasia was quite different. Of the other explanations put forward for the conditions now ascribed to pressure none were convincing.

Asked if there was any correlation of deformity with foetal movements, Mr. Browne said he had had several cases of deformity where the mother had felt less movement than usual, but he thought the sensations were produced by knocks of the child's hands and not by kicks. The hands were usually free in these cases. He could not offer an explanation of the presence of six fingers.

#### Miscellaneous Diseases

Dr. REGINALD LIGHTWOOD reported, on behalf of Drs. N. F. MacLagan and J. G. Williams and himself, a case of *persistent acidosis of unknown cause*. The child showed surprisingly hypotonic muscles and fair nutrition when first seen, but later became gravely ill with bronchitis, diarrhoea, and vomiting. A study of six cases showed a syndrome of wasting, muscle hypotonia, a trace of albuminuria, occasionally blood-cells and bacilli in the urine, and coarse calcium deposits in the boundary zone of the kidney. There were no other disorders of the kidney, and all cases so far seemed to have died with a terminal infection. The case presented had appeared to resemble this syndrome and had shown persistent acidosis. After treatment by rectal saline and glucose the child had recovered.—Dr. MACLAGAN pointed out that the child had had a severe acidosis which appeared to break all the ordinary rules and for which no cause was apparent.—Dr. DONALD PATERSON said the syndrome was recognisable, once seen. Foreign body in the kidney was strongly suggested by an ailing, vomiting child between 6 and 12 months of age, with albumin and large lymphocyte-like cells in the urine. The prognosis was very bad.—Dr. LIGHTWOOD emphasised the importance of keeping patients free from infections and from overdosage with vitamin D. The kidney condition resembled D-poisoning in animals, but in the cases recorded the children had not had D-concentrates. Alkalis might be given to correct the acidosis.

Dr. REGINALD WILSON (for Dr. Paterson) showed a case of *actinomycosis of the lung* involving the chest wall in a girl of 9. The child had been given vaccine and had apparently recovered.—Dr. PATERSON pointed out the rarity of recovery in such cases.—The PRESIDENT said the only cases of actinomycosis he had seen recover were those in the right iliac fossa.—Dr. K. H. TALLERMAN said that in a case he had known the patient had been apparently well for three years but was now in hospital going rapidly downhill.

Dr. WILSON also showed a case of *congenital blindness* in a male aged 5 months. An uncle and three cousins had all been blind and died young. All the affected members of the family were males and half the females of the family were producing defective children. An eye had been removed from one of the cousins and showed gliosis of a detached retina which was not as much as was usual in a glioma. Dr. Greenfield preferred to call it an exudative, proliferative choroiditis. The diagnosis lay

between glioma, pseudoglioma, and the familial hereditary angiomatous retina.—Dr. E. A. COCKAYNE said that glioma retini was never a sex-linked recessive.

Dr. T. COLVER (for Dr. Paterson) reported a case of *ethmoidal suppuration* with orbital involvement; external drainage had led to rapid improvement.

Dr. G. H. NEWNS (for Dr. Paterson) showed encephalograms of a case of *subarachnoid hæmorrhage* in a child of 7 who had fallen on his head a month earlier. No evidence of subdural hæmorrhage had been found. The trauma must have ruptured a small aneurysm which had leaked for a while, then bled more actively and clotted up.

Dr. TALLERMAN reported a case of *infantile myxœdema* in a girl of 5 who had appeared normal up to the age of 2. The child was now much the same size as at that age. Acquired thyroid deficiency was very rare. The radiograms showed delayed ossification of femoral heads.—Dr. PATERSON had only seen one case: a small boy who developed an adenoma of the thyroid at the age of 4, and became normal on thyroid treatment.—Dr. COCKAYNE also had only seen one case. The prognosis was much better than in a cretin.

Dr. P. R. EVANS (for Dr. Wilfrid Sheldon) showed a case of *pneumothorax and bronchial collapse following chest injury* in a girl of 9. A car wheel had passed over the chest and fractured the right third and fourth ribs. Bronchoscopies to enable air to enter the lung had been partially successful, and the patient had been able to return to school and to win a 100-yards race; the heart was still to the right of the sternum and the right lower and middle lobes collapsed. The collapse of the bronchus had protected the lung from infection. Lobectomy did not seem indicated.—Dr. PATERSON asked if carbon dioxide and oxygen had been given.—Dr. EVANS replied that the accident had occurred three years before and there was little chance now of aerating the remaining lobes.

Dr. J. V. BRAITHWAITE showed a case of *myopathy* in a girl aged 5 with no family history and a history of not having walked until 3, which was against pseudo-hypertrophic muscular dystrophy.—Dr. COCKAYNE thought this condition occurred sometimes in girls and might be either a recessive or a sex-linked recessive.

#### NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

At the last meeting of this society, held in Leeds, with Dr. RUTH NICHOLSON, the president, in the chair, a number of cases were reported.

##### An Unusual Metastasis

Mr. A. GOUGH described a case of carcinoma of the cervix uteri with metastases in the glands of the neck.

The patient, a 9-para aged 66, presented herself in February, 1935, because of a discharge of blood, which had already continued for six months. A typical cancerous excavation of the cervix was found. The growth appeared to be invading the base of the bladder, and it was classified as Stage III. Histologically it was found to be a squamous carcinoma of an ordinary cervical type.

The patient was treated with radium by the Stockholm technique. She received three applications—3200 mg.-hours on each occasion. The immediate result was good.

She came up for examination after three months and again at the end of six months, and everything was found satisfactory. At the end of twelve months there was still no sign of recurrence in the pelvis, but enlarged glands were found in both subclavian triangles. On the right side there was a gland the size of a cherry; on the left side it was the size of a bantam's egg, and it was obviously adherent to the subclavian vessels. The gland was removed from the right side of the neck, and section showed the structure of a squamous carcinoma of the same type as the uterine growth. The patient was sent to the radium department for treatment of the neck.

Mr. Gough thought the cancerous deposits in the glands of the neck might reasonably be supposed to be metastases from the uterine growth, for they were of the same type and there was no evidence of any other primary source. The disease had presumably travelled along the thoracic duct. This was the first time he had seen such extension to the neck in a case of cancer of the uterus, and he did not remember ever to have read of it. It had, however, occasionally been observed in connexion with cancer of the ovaries and other abdominal organs. Other observers had commented on the greater frequency of metastases after the radium treatment of cancer of the cervix. The treatment, it seemed, succeeded in abolishing the growth within a certain radius, but there might be continuing spread at the periphery, where the intensity of the radiations had been insufficient to destroy the cancer cells.

Mr. ERIC STACEY (Sheffield) was inclined to think that carcinoma sometimes spread by way of the blood stream, metastatic emboli being produced as an effect of the radium treatment.—Mr. B. L. JEAFFRESON had seen a case of first-stage carcinoma of the cervix, in which metastases had already extended to the bronchial glands, as demonstrated by radiography.

#### Tuberculosis of the Uterus

Mr. Gough also reported a case of tuberculosis of the pelvic organs.

The patient, an unmarried woman of 21, complained of increased menstrual loss for the past ten months, the periods lasting as long as a fortnight, although the intervals were clear. There was no pain and no other symptom. Her general condition was good; she was well nourished, and did not appear anæmic.

On abdominal examination nothing was made out except general tumidity in the lower zone. By the rectum it was possible to feel a mass the size of a large orange. It was inseparable from the uterus, and several prominences could be felt on its surface. Its mobility was decidedly less than that usually found in a case of myoma of the uterus. Nevertheless, in spite of the youth of the patient, a provisional diagnosis of myoma was made, and operation was performed on April 3rd.

The abdomen was opened by a left paramedian incision. Universal adhesions were found among the pelvic organs, and on separating these, some ounces of yellow serous fluid escaped. Many of the peritoneal surfaces were seen to be studded with tubercles. The uterine appendages formed irregular swellings on both sides, and the uterus itself was considerably enlarged. From this enlargement, and taking into consideration the menorrhagia, it was concluded that the uterus must be involved in the disease. It was therefore removed, with both appendages. When the uterus was cut open, it was seen that the enlargement was mainly due to a thickening of the myometrium. There was also a tuberculous endometritis. The upper part of the corporeal endometrium was studded with yellowish tubercles. The characteristic structure was seen in microscopic sections.

Mr. Gough considered that tuberculosis of the Fallopian tubes was not uncommon, but in his experience it was rare to find tuberculosis of the uterus.

Here he was leaving out of consideration the scattered miliary tubercles which are seen on the outer surface of the uterus in cases of tuberculous peritonitis. This was only the second occasion on which he had removed a uterus for tuberculosis. The first case was very similar to the present one, and the patient, refusing sanatorium treatment, had died six months after operation from general tuberculosis.

Mr. STACEY believed that tuberculosis of the genital tract was commoner than was generally supposed. During the past three months he and his colleagues in Sheffield had found tuberculosis in nine cases—proved by section of curettings.—Mr. ST. GEORGE WILSON (Liverpool) was of opinion that the endometrium was as a rule also involved in cases of tuberculous salpingitis. In treatment he preferred X rays to surgery.—Prof. MILES PHILLIPS (Sheffield) thought that if careful inquiry were made a history suggestive of tuberculous peritonitis in childhood could often be obtained. The trouble might lie dormant and be lit up after marriage.—Mr. GOUGH, in reply, expressed surprise at the high incidence which was apparent in Sheffield as compared with Leeds. He stated a personal preference for operative treatment.

Mr. W. R. ADDIS read a note on impaction of the bladder, and Mr. D. W. CURRIE reported a case of hæmorrhage into an ovarian tumour at the third month of pregnancy.

## REPORTS AND ANALYSES

### PATZENHOFER GENUINE GERMAN LAGER BEER (LIGHT)

(JOHN C. NUSSLE & CO., LTD., 21, SOHO SQUARE, LONDON, W.1. SOLE CONCESSIONAIRES FOR GREAT BRITAIN, I.F.S., AND EXPORT)

THIS well-known beer is of the Pilsener Lager type, and is brewed and bottled at the Patzenhofer Brewery, Berlin. When analysed the following results were obtained:—

Original gravity before fermentation ..	1049°
Present gravity .. .. .	1009°
Alcohol by volume .. .. .	5·18 per cent.
Equivalent to proof spirit .. .. .	9·03 " "
Matters in solution .. .. .	4·19 " "
These include—	
Carbohydrates (maltose) .. .. .	1·41 " "
Dextrin, hop extract, &c. .. .. .	2·37 " "
Proteins .. .. .	0·23 " "
Mineral matter .. .. .	0·12 " "
Acidity (as acetic acid) .. .. .	0·06 " "
Carbon dioxide .. .. .	1710 c.cm. per litre.
Sulphurous acid .. .. .	2·24 grains per gallon.

The beer is very pale in colour and has an agreeable palate typical of a high-class export lager, and with a less pronounced hop flavour than English bottled beer. About two-thirds of the original gravity was lost during fermentation. The content of carbon dioxide is normal for a bottled beer; the sulphurous acid present is negligible, and was derived from the raw materials used in brewing. The beer is brilliant and entirely free from any sediment.

HOSPITAL COÖRDINATION AT LEEDS.—A scheme for the coördination of the voluntary and municipal hospitals is being evolved at Leeds, and a committee has been appointed by the city council to meet representatives of the voluntary hospitals.

## REVIEWS AND NOTICES OF BOOKS

**The Medical Annual**

By Various Contributors. Edited by H. LETHEBY TIDY, D.M. Oxon., F.R.C.P., and A. RENDLE SHORT, M.D., B.Sc., F.R.C.S. Fifty-fourth year. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 845. 20s.

To decide what book is most worthy to be called the general practitioner's bible might prove no easy task but the Medical Annual would certainly be in the short list. The 1936 edition contains much new and important material. Sir Weldon Dalrymple-Champneys writes on undulant fever and Sir Leonard Rogers, F.R.S., adds a note on atypical forms of that disease. Dr. A. H. Douthwaite contributes articles on gout and chronic rheumatic disorders. Another newcomer is Mr. K. H. Pridie, who collaborates with Prof. Hey Groves in six articles on orthopædic subjects. The article on therapeutics, by Dr. Philip Hamill, discusses among other controversial matters the vexed question of the barbiturates. Mr. Sampson Handley writes on diseases of the breast, and Dr. John Underwood on the school medical service. There is a long and authoritative article by Sir Morton Smart on manipulative surgery; this should inspire the practitioner who reads it to be less timorously conservative than hitherto in his treatment of minor but disabling injuries to bones and joints, with benefit to his patients and, incidentally, to his own professional reputation. With the exception of two writers on para-medical subjects, the only notable absentee among the contributors to this year's Annual is Dr. Robert Hutchison. The editors, as usual, are also contributors—Dr. Tidy writes on various intra-abdominal disorders, and Mr. Rendle Short contributes more than a dozen articles on various aspects of abdominal surgery, including one on adrenalectomy. Much recent work on blood diseases is described, including a reference to the treatment of hæmophilia with Russell's viper venom, now available on the market. An interesting article is that on malaria and its treatment with atebtrin and atebtrin mussonate, and a sensible note deals with the diet of athletes. Attention is drawn to the recently noted association between gall-bladder and heart disease, and there is a long article on the all-important pituitary. The increasing potentialities of surgery, especially that of the thorax, are discussed. We learn that, in the last decade, the mortality of lobectomy has fallen from 80 to 14 per cent., and that pneumonectomy is now quite practicable. "Chronic interstitial mastitis" in patients under forty is said to respond well to treatment by X rays and ovarian extract. Certain neoplasms of the lung also respond well to radiation. Otosclerosis is being treated with thyroxine. Radiology is proving increasingly valuable in cardiology, antenatal examination, and even in the differential diagnosis between pneumonia and acute abdominal conditions. Cyclopropane is held to be perhaps the most promising of the new anæsthetics, but vinethane and supersaturated ether are being tried out with success.

These are a few of the interesting pieces of information taken at random from this book. The editors note with satisfaction in the introduction to the Annual that the material gleaned from another year's medical literature shows "that there have emerged an unusually large number of comparatively simple methods of new treatment, for a great diversity of ailments, well worthy of the attention

of every practitioner who desires to relieve his patients safely, quickly, and pleasantly."

**A Textbook of Surgery**

By American Authors. Edited by FREDERICK CHRISTOPHER, B.S., M.D., F.A.C.S., Associate Professor of Surgery at Northwestern University Medical School; Chief Surgeon, Evanston (Illinois) Hospital. London: W. B. Saunders Co., Ltd. 1936. Pp. 1608. £2 2s.

THIS text-book of surgery, designed for the use of undergraduates, is interesting from several points of view. It deals with the whole of surgery except that of the special senses, and although it contains over 1600 pages it has been kept to a reasonable size. Its most remarkable feature is the number of contributors who include men of world-wide reputation: Henderson, Smith-Petersen, Adson, Rankin, Balfour, Blair, Bunnell, Graham, Ivy, Orr, among others. The editor has selected them not only because of their special knowledge of the particular section of surgery about which they write, but also because they are, for the most part, teachers who are known to possess gifts of exposition.

The result is a book which is thoroughly up to date, and, moreover, makes attractive reading. The extreme subdivisions of subjects show how very specialised is surgery in America to-day. For example, there are separate authors for femoral and inguinal hernia; five deal with the rectum, and seven with the stomach. No less than nineteen authors write on fractures of the limbs. One gathers that the one who describes fractures of the shaft and upper ends of the tibia and fibula is not considered so great an authority on fractures of the lower ends of these bones; the coöperation of two experts has been deemed necessary on the question of fractures near the elbow-joint, and the same applies to fractures of the phalanges and metacarpals. It is not astonishing that the contributions are uneven in quality. Among the inadequate sections is that on tuberculous disease of the hip, which though it may be a rapidly disappearing disease still merits more notice than seven lines of print for its pathology and twelve and a half lines for its symptomatology and treatment combined. That this article is illustrated by some good pictures of the not very common operation for extra-articular fusion of the joint only emphasises the omission of a full account of the disease. The sections on Pott's disease of the spine and on diseases of the tongue are also too brief. The good sections far outnumber those which do not present their subject in a way suitable for the undergraduate. A useful feature is the break away from tradition in arrangement; to give only one example, painful affections of the lower back are discussed together in a most effective way, instead of being treated in separate compartments according to the anatomical lesion. The modern outlook is presented in such a manner that life is infused into the duller subjects and the reader's interest is held throughout.

The book cannot fail to stimulate all who read it. Students will use it as an adjunct to a practical course of demonstrations or lectures in surgery, and surgeons and practitioners will wish to possess it because it contains first-hand teaching by many leaders of surgery.

## The Medical Dictator

*And Other Biographical Studies.* By Prof. MAJOR GREENWOOD, F.R.S., D.Sc., F.R.C.P. London: Williams and Norgate Ltd. 1936. Pp. 213. 7s. 6d.

Prof. Major Greenwood has already earned our gratitude by his introduction to the study of epidemiology entitled "Epidemics and Crowd Disorders." The literary grace, the learning without parade, and the spontaneous use of epigram displayed in that book, will all be found in his new volume of essays. Each chapter in the *Medical Dictator* is composed of acute desultory musings on six men of an absolutely different standing in their common profession of medicine and in their influence on society. This reviewer does not propose to select one chapter more than another as worth attention; they should all be read—a pleasant task, though the easy reading implies hard writing.

The men introduced to us are Galen, Freind, Peter Mere Latham, William Farr, Pierre Louis, Osler, and Arthur William Bacot. Galen, for some 1500 years the medical dictator of the civilised world, is put in his place as an overrated thinker, who none the less had influence for good, probably in an unintentional manner. Freind, the author of the "History of Physick," is an unfamiliar name to most of us, and such references as may occasionally be seen allude to him as a Latinist, in which character he would make a sure appeal to his biographer. Prof. Greenwood says of him, in reference to his diagnostic and therapeutic methods, that "he is as clear as Macaulay and he has demonstrated completely that he was wholly destitute of the qualities which make a scientific investigator," adding that he must not be sneered at for ignorance of things which have been discovered since his death. But the little biography closes with the suggestion that Freind owed the regard in which he was held not to his learning but to his hatred of pretence, the real reason why Freind was beloved "and why a gracious memory of a stout-hearted, enjoying English gentleman and scholar has come down to us," being his intolerance of dictatorship. He is bracketed with Osler and Allbutt of our own generation in a genuine affection for the humaner letters, and with P. M. Latham for his scorn of affectation.

In the chapters on William Farr and Pierre Louis Prof. Greenwood is dealing with pioneers in the section of learning which he himself adorns. He finds Farr to have arrived at his general deductions by methods that a properly equipped actuarial mathematician would regard with horror, but none the less he endorses an official description of him attributing to his work great services for the advancement of national health. The numerical method of Louis is closely criticised, and the difficulties to be overcome in establishing a scientific system in diagnosis and prognosis in the manner of which Louis hoped for are recognised. But Louis did not obtain the support of the medical profession, and the systematic use of statistical methods in clinical medicine never entered into the routine of French hospital work. This fact provides Prof. Greenwood with the caustic commentary that "if only Louis had succeeded in really commanding the support of the great clinical teachers of Paris, why, we should have had to do something about it in England." Osler is sympathetically if not over respectfully treated, and an amusing piece of leg-pulling is retailed where Osler, the hardened joker, is himself the victim of "Popsey" Welch. The closing chapter is a biographical sketch of Bacot, the great entomologist;

it is a record of an intimate friendship which provides at the same time a vivid picture of Bacot's wonderful technique.

Prof. Greenwood succeeds in these charming essays in justifying his view that the lives of all his subjects give a favourable impression of human nature; but we feel that he finds human nature to be frequently frail, and this estimate escapes him in the guise of quotation and quip.

## The Diagnosis and Treatment of Pulmonary Tuberculosis

By JOHN B. HAWES, M.D., President of the Boston Tuberculosis Association; and MOSES J. STONE, M.D., Assistant Professor, Diseases of the Chest, Boston University School of Medicine. London: Henry Kimpton. 1936. Pp. 215. 12s. 6d.

A SHORT book of this kind, which is addressed to practitioners, students, nurses, and social workers, cannot be made complete, and the best work for its purpose is one which combines lucid exposition with correct emphasis of those aspects of the subject which, in the light of recent knowledge, are held to be the most important. Judged by these standards this is a first-rate book. In the opening chapters the authors point out that evidence of active disease which is not at once volunteered by the patient may often be obtained by careful history-taking. Physical examination of the chest is discussed adequately but refinements of detail, especially in percussion, are discouraged, a few honest persistent râles being regarded more seriously than much doubtfully impaired resonance. Although the study of physical signs should not be neglected, the writers note that radiology is now taking such an important place in the routine examination of the lungs that percussion must take second place in the detection of areas of consolidation. Tidal percussion of the bases is unnecessary when the movement of the diaphragm can be seen so much more clearly by screen examination. "Do not waste time over *non-essentials*. Much time has been wasted, for instance, in percussing out the narrow strip of normal resonance, known as Krönig isthmus"; this is an extract typical of the practical common sense which pervades the book.

In the chapters on treatment the sanatorium is described as being the best place for the great majority of early cases; it should be situated relatively near the patient's home. It is conceded that the much vaunted climate of Colorado may offer something to the consumptive who can afford to go there, as the surroundings are certainly more beautiful and the weather more pleasant than for example in New England, but it is emphasised that quite satisfactory results are obtained near sea level in the Eastern States. In contrast to some recent American writers, the authors are not obsessed with the risks of adults catching tuberculosis from one another. Infection of children should be rigorously avoided, but although precautions should not be neglected in adult contacts the problem here is considered to be much more one of hygiene than infection.

Among the concluding chapters that on rehabilitation in pulmonary tuberculosis deserves special mention; occupational therapy in the sanatorium, the sheltered workshop, and the farm or industrial colony all have a place in the struggle against tuberculosis. The Papworth scheme is looked on as providing the ideal after-care and this is one which should have many

imitators. There is room for criticism only in the reproduction of some of the X ray films, but it would be ungrateful to expect higher value than is here given for such a modest sum as is charged for this excellent book.

## MEDICINE AND THE LAW

### Medical Officer's Action Against Mental Hospital

THE action brought by Dr. Hugh Charles McManus, formerly assistant medical officer to the Park Prewett Mental Hospital near Basingstoke, ended unsuccessfully last week after several days of litigation. He claimed damages under heads so various as conspiracy, libel, negligence, breach of contract, and wrongful dismissal. He sued (a) Dr. R. F. B. Bowes, the former medical superintendent of the Park Prewett Hospital, (b) the late Duke of Wellington as chairman, and two other defendants as members, of the hospital visiting committee, (c) the clerk to the hospital, and (d) the clerk to the Hampshire Joint Mental Hospital Committee. He complained that Dr. Bowes had wrongfully induced the hospital authorities to break their contract with him. The plaintiff's case was eloquently opened with allegations which the different defendants were unlikely not to resist. Dr. McManus was represented as an enthusiastic and enterprising young medical officer who, on coming to the Park Prewett Asylum in 1923, found it run on mechanical lines—not a single modern text-book, no scientific instruments, the clinical examinations taking place in the wards, no pathologist, X ray treatment administered by the resident engineer who was not a radiologist, post-mortem examinations carried out by an unqualified person, and so on. Dr. McManus, it was suggested, made his reforms at the expense of his popularity. He altered the inadequate system of keeping records and he won his fight for a separate room for clinical examinations. His zeal was unappreciated and he was subjected to petty annoyances. His health suffered from the strain of obtaining the diploma of psychological medicine: the matron used to give him a cup of beef tea at 11 A.M., but, when he gained his diploma, she was forbidden to do so. There was an objectionable slander about a nurse being seen to leave his room in the evening; it was even said that he drugged himself. His health finally broke down. He was told to leave, and, since October, 1927, he had been unable to obtain further appointments.

All these allegations the defendants denied; they merely said that Dr. McManus, if he were entitled to any notice at all, was given proper notice to terminate his engagement. At the closing of the evidence for the plaintiff, the case against Dr. Bowes was found to be unsubstantiated. Eventually Dr. McManus withdrew all his charges and claimed only damages for wrongful dismissal and the return of his superannuation contributions. Mr. Justice Macnaghten, who was trying the case with a special jury, thereupon ruled that it was undesirable that the same jury, after hearing so many matters which were not now being proceeded with, should be asked to determine the lesser issues which remained. It might be hard for the jurors to dismiss from their minds the copious evidence which was now largely irrelevant. He therefore dismissed the jury and announced that a fresh jury would be sworn in for deciding the remaining question whether Dr. McManus was entitled to three months' notice or not. On this

point the plaintiff's counsel argued that Section 189 of the Public Health Act of 1897 (giving express authority to dismiss an officer "at pleasure") did not apply: no such words were to be found in Section 276 of the Lunacy Act, 1890: the whole policy of the Asylum Officers' Superannuation Act, 1909, indicated some permanence of tenure for the staff of mental hospitals. On the other hand, the defendants contended that Section 276 of the Lunacy Act justified the hospital committee in revoking the appointment of Dr. McManus at its pleasure and without assigning any reason; if so removed, he could not, of course, draw the salary and emoluments of the office; his position was not affected by the Local Government Act, 1933, which enabled local authorities to agree that notice should be given to a medical officer.

When the case was ready to proceed afresh under the new jury, Dr. McManus was unfortunately ill and unable to give evidence on the question of his dismissal. The judge thereupon gave his decision upon the arguments. Observing that neither at the time of the plaintiff's engagement nor at any other time was there any mention of notice, the court decided that he was employed at the committee's pleasure; the terms of his engagement implied that he could have no complaint if the committee told him to leave. With regard to the claim for the return of his superannuation contributions under the 1909 Act, he could only be entitled to have them back if he were not entitled to a superannuation allowance. He had claimed superannuation allowance in an application to the Home Office. The hospital could not repay the contributions while that claim was pending. At the date of the writ in 1933 Dr. McManus was not entitled to receive the deductions made under Section 10 of the 1909 Act; the claim for superannuation allowance was finally decided against him by the Home Office and the court thought the question could not now be reopened. The result was that Dr. McManus lost at all points and the whole of his actions were dismissed with costs against him.

### Complaint of Wrongful Certification

The Sunderland town council has lately discussed a complaint that a sane boy was wrongly certified and sent to the borough mental hospital. It seems to be agreed on all sides that the boy was backward and undeveloped. It is alleged on behalf of his parents that he needed nourishment and that his tonsils should have been removed but that there was no occasion to send him to an asylum. It is said on the other side that he was a boy of 17 with the mentality of a child of 10 or 12 and that he left the mental hospital in a condition greatly improved by treatment. The town council decided by 11 votes to 7 (the majority of the councillors abstaining from voting) to ask the Minister of Health to hold an inquiry into the circumstances. The matter being thus sub judice, further statement or comment may be postponed. It may, however, not be improper to record an expression used in the council chamber by a speaker who referred to "the stigma which this boy will have to carry for the rest of his life." A Royal Commission suggested certain reforms which were afterwards enacted in the Mental Treatment Act of 1930. Its report reminded us that the proper treatment of doubtful cases in mental hospitals is in the best interests of the patients. It may be hoped that some day our social standards will be so changed that treatment for mental ailments, great or small, will be regarded as no more shameful than treatment for mumps or measles.

# THE LANCET

LONDON: SATURDAY, MAY 30, 1936

## ANXIETY ABOUT HOSPITAL FINANCE

In his introduction to that modern epic, Evans and Howard's "Romance of the British Voluntary Hospital Movement" (London, 1931), Sir W. ARBUTHNOT LANE spoke of a new era ending the hygienic chaos with which the voluntary hospitals have been striving for centuries to deal. He was referring to the effect of the Local Government Act in opening vast new sources of revenue to historic institutions—which were finding it increasingly difficult to carry on—by making it possible for the municipalities to contribute without interfering with their voluntary character. The great voluntary hospitals, he said, are called upon to lead in a way they have never before been called upon to lead in their history, for the new law enables the people to organise the followers without any fear of overlapping, conflict, or, worse still, the deterrent stigma of pauperism which attached to the old infirmaries. Nevertheless the Hospitals Year-Book, which has just appeared<sup>1</sup> for the sixth time, betrays some anxiety about the position of the voluntary hospitals.

There is no question about the extent or the urgency of the work that these hospitals are doing; in the year 1934 which is reviewed 1,300,000 patients were treated in their wards and 6,000,000 patients in their out-patient departments, being an increase of 60,000 and 285,000 over the numbers treated in the preceding year, an increase described in the Year-Book as normal. At the same time the difference between a 100 per cent. occupation of beds in some of the large hospitals and a 10 per cent. occupation in some of the small ones suggests that due weight has not been given to the factor of transport facilities, and the lesson of overcrowding of large hospitals by patients from the country district has not been borne in mind. Mr. R. H. P. ORDE, the able editor of the Year-Book, expects no improvement in the situation until agreement has been reached about the proper place of the cottage hospital in the general health scheme of the country. Recalling the declaration in the Cave report of 1921 that the voluntary hospital system, which is peculiar to the English-speaking peoples, is part of the heritage of our generation, Mr. ORDE remarks that the future of these hospitals does not depend upon a brave phrase and a consciousness of their own integrity, but upon action of a kind to which they are by the nature of things unaccustomed and

for which they are singularly ill-equipped. It was, he thinks, for this reason that in the Act of 1929 the voluntary hospitals figured only in one small section, inserted almost grudgingly at the last moment; and even the passing of that Act awoke them from their complacency for only a little time. It was not until June of last year that the British Hospitals Association at the Leamington conference set up a commission under Lord SANKEY to develop their policy and safeguard their future. This commission has asked the county councils and boroughs what they have done, in making provision for hospital accommodation under the Act, to consult with the voluntary hospitals. It seems that no more than 83 of the 146 authorities have set up voluntary hospital committees. Moreover, in 34 instances the formation of such a committee has been the end of the matter; only in 16 instances have joint committees been formed representative of the public authorities and the voluntary hospitals. The county areas in general are profoundly inactive.

SIR CHARLES HARRIS tells much the same story in his financial review. He is not dazzled by the magnificent net surplus of a million pounds on the maintenance account in the aggregate, for he demonstrates the existence of a numerous class of hospitals waterlogged by the accumulated weight of successive annual deficits. The day of high-pressure begging is, he thinks, gone; at any rate it is likely to obey the law of diminishing returns, and in many places the contributory schemes have their own management funds and reserves, so that what the hospital receives is in the nature of payment for services rendered. What most troubles him is the downward trend of the free legacy. The peak was reached with £20 per available bed in 1927-28, and the figure is now below £17. Expenditure on the other hand continues to rise; the average increase over the previous year was £3.1 per available bed, the largest component being under the heading of salaries and wages. The only prospect of reducing future expenditure lies, he thinks, in constructive economies, the possibilities of which are still unexhausted. But year after year a substantial minority of provincial hospitals refuse to adopt the uniform system for hospital accounts which would make comparisons valid and combined action possible. This stone-walling of purposive central effort is one of the unlovely characteristics of voluntarism. Sir CHARLES HARRIS speaks of the complete absence of team spirit in a minority of units which goes far to destroy the value of the whole scheme.

## CHOLANGIOGRAPHY

THE visualisation of the biliary ducts by direct injection of fluids opaque to X rays, in contrast to cholecystography by the recognised routes of oral or intravenous administration, has been done occasionally in selected cases for more than a decade. Tenney and Patterson<sup>1</sup> in 1922 investigated

<sup>1</sup> The Hospitals Year-Book 1936: an annual record of the hospitals of Great Britain and Ireland incorporating "Burdett's Hospitals and Charities." Issued under the auspices of the Joint Red Cross Council and the British Hospitals Association by the Central Bureau of Hospital Information, 12, Grosvenor-crescent, London, S.W.1, pp. 336, 198.

<sup>1</sup> Jour. Amer. Med. Assoc., 1922, lxxviii., 171.

a case of external biliary fistula by injection of bismuth paste under pressure; the pyrexia, jaundice, and abdominal pain which followed were probably due to temporary blocking of the common bile-duct. Mallet-Guy, Beaupère, and Armanet<sup>2</sup> in 1927 used lipiodol for the same purpose, and in 1930 Ginsburg and Benjamin<sup>3</sup> reported a series of cases of post-operative biliary fistula in which the injection of lipiodol proved to be of much diagnostic value when X rays were taken immediately. In the absence of active infection of the bile-ducts they found such injections to be simple and safe when done under fluoroscopic control, and showed that if the common bile-duct is unobstructed, lipiodol injected into an external biliary fistula appears almost immediately in the duodenum; the intrahepatic bile-ducts were rarely outlined unless there was some organic obstruction of the common bile-duct. In 1930 W. B. Gabriel<sup>4</sup> described a case in which the common bile-duct had been drained by a T-tube following removal of a large stone; some three weeks later proof of the patency of the common bile-duct was obtained by the injection of lipiodol through the tube prior to its removal. A similar use of lipiodol through a tube inserted at operation for purposes of drainage has been reported by R. H. Overholt (1931), A. H. Kretchmar (1933), and Judd and Phillips (1933). J. Cosbie Ross<sup>5</sup> has recorded a considerable experience of lipiodol in these cases. On account of the rapidity with which lipiodol passes into the duodenum a small residual stone in the common duct is not likely to be shown unless it is causing obstruction. The lipiodol may be held up at the lower end of the common bile-duct, either through spasm of the sphincter of Oddi or to impaction of a stone; if it is spasm that causes the obstruction injection of atropine, followed after three-quarters of an hour by a further radiogram, may show that the lipiodol has passed into the duodenum. This condition of abnormal tonus of the ampullary sphincter, or biliary dyssynergia, is of importance; B. R. Best and N. F. Hicken<sup>6</sup> note that it may occur independently from cholangitis, stones, or duodenitis, and lead to hepatic neuralgia and the occasional persistence of symptoms after cholecystectomy. Direct injection into the common bile-duct is not the only way of using lipiodol as an aid to diagnosis in this region. It may be run into the gall-bladder after cholecystostomy in order to investigate the cystic and common bile-ducts. Chiraz and Lomon<sup>7</sup> have obtained excellent radiograms by its injection through cholecystostomy catheters; these may show, for example, gross distension of the common bile-duct from impaction of a calculus and dilatation of the intrahepatic bile-ducts from compression of the hepatic ducts by secondary carcinomatous deposits.

The most recent application of cholangiography was initiated by Mirrizi<sup>8</sup> who reported successful visualisation of the biliary ducts while the patient was on the operating table, the method adopted being the insertion of a T-tube into the common duct, the injection of lipiodol and an immediate X ray. Robins and Hermanson<sup>9</sup> now describe, with many valuable details, their results in 25 cases in which this technique was used. The patient is placed on the operating table with a metal tunnel holding a 14 by 17 film under his back. The abdomen having been opened the cystic duct is identified and clamped; then by means of a 30 c.cm. syringe and a No. 15 or 18 gauge needle, 20 to 25 c.cm. of Hippuran (a 40 per cent. aqueous organic iodine solution) are injected into the common bile-duct. The surgical team makes way for a portable X ray apparatus to be wheeled into position and an exposure is made. In six minutes the surgeon should be able to see the developed film, and may thus gain visual help in deciding whether or not the common duct should be opened. If, for instance, an obstruction due to the impaction of a calculus is revealed the duct is opened and the stone removed; a T-tube for drainage is inserted and by a further injection of hippuran (30 c.cm.) the surgeon can see if his efforts to remove the obstruction have been successful. Robins and Hermanson say that in 24 of the 25 cases examined in this way accurate visualisation of the condition present was obtained. The only contra-indication to the method seems to be acute infection of the biliary tract. A further interesting observation was that in each of the 4 cases in which the pancreatic duct was visible abdominal exploration showed chronic pancreatitis to be present.

Surgeons able to command the necessary facilities by the provision of a shock-proof X ray apparatus in the operating theatre should take note of this work. Cholangiography may evidently provide valuable assistance, not so much in the typical case of gall-stones, as where there is a history of jaundice, or where laparotomy shows a dilated common bile-duct, or in those difficult patients in whom an operation on the biliary tract has been performed previously and recurrent symptoms necessitate a further exploration.

## STORAGE OF BLOOD FOR TRANSFUSION

IN Soviet Russia for many years the blood of corpses has been used for transfusion; yet the method is seldom mentioned in the medical journals of Western Europe and America. Lately YUDIN, surgeon-in-chief of the Sklyfasovsky Central Emergency Hospital in Moscow, has provided needful information by reporting in both English<sup>10</sup> and French<sup>11</sup> on a thousand transfusions performed with cadaver blood.

The idea of using blood from casual corpses for

<sup>10</sup> Yudin, S. S.: Jour. Amer. Med. Assoc., March 21st, 1936, p. 997.

<sup>11</sup> Judine, S.: Presse méd., Jan. 11th, 1936.

infusion into living human beings is at first thought repugnant, and though the distaste is purely sentimental it is easy to rationalise it. For example, we may urge the danger of infection and the possible toxic effects of hypothetical post-mortem changes in the blood. But M. G. SKUNDINA and S. I. BARENBOIM, working in the Sklyfasovsky Institute, seem to have overcome these and most other non-sentimental objections. They find that the blood must be taken from bodies in which life has not been long extinct; the limit of time after death for withdrawal is arbitrarily set at six hours in summer and eight in winter; moreover, death must have been sudden and preferably from an acute cardiac condition or electrocution. Using such corpses and withdrawing the blood through cannulae inserted into the jugular veins with the body in the Trendelenburg position these workers find it to be sterile; they have demonstrated that the blood of the portal circulation is the first to become infected by organisms after death and that this is not tapped by the method used. Their inquiries also bring to light a further point of great interest. They find that blood abstracted in this way from the corpse of a person who has died suddenly coagulates almost at once but liquefies again in 1-1½ hours; this peculiarity they state to be shared by the blood of patients still living but in a state of profound shock. Blood taken from the corpse of a person who has died slowly, on the other hand, clots and remains clotted. This observation obviously calls for further investigations, and these are promised. YUDIN states that the decoagulated blood derived from the body a few hours after sudden death actually gives rise to fewer reactions than citrated blood.

At a temperature of 1-3° C. cadaver blood keeps well, and it has been successfully infused after a month's storage. By using cadaver blood YUDIN and his associates have been able to keep on tap an ample supply for all emergencies. To make available such a supply, however, calls not only for an ample supply of suitable corpses but also for a highly organised system. On both these considerations—leaving prejudice aside—it is unlikely that under present circumstances the practice will come into vogue in this country. And inasmuch as cadaver blood appears to have no advantage over that from living men and women, which is readily obtainable here, there seems to be no reason why it should. The question of the storage deserves none the less more attention than it has hitherto received. It is the custom in this country to infuse blood shortly after its removal, and for this purpose donors are called upon, often at considerable inconvenience to themselves, as required for individual cases. Yet there is no apparent reason why stocks of Group O blood should not be kept on hand in institutions performing many transfusions; or some central institution might serve large areas of the country with bottles or cans of blood as required. PALAZZO and TENCONI,<sup>11</sup> of Buenos

Aires, are among the few that have recorded observations on the keeping properties of blood and its transmission, and blood sent by them from South America has been successfully infused by JEANNENEY and VIÉROZ<sup>12</sup> in Bordeaux. The Argentine workers took the blood into citrate, centrifuged out the red cells and suspended them in a mixture of two parts of 3.8 per cent. citrate solution and five parts of either 10.3 saccharose or 5.4 dextrose solution. For infusion the red cell emulsion was given either alone or after recombination with its plasma. Whether any advantage attaches to this separation of red cells and plasma appears to be doubtful; the whole problem stands in need of further study.

## GUY'S HOSPITAL REPORTS

THE present issue of *Guy's Hospital Reports* is a centenary number; for the first volume, its editor believes, appeared in 1836, although, as it was reviewed in THE LANCET dated Jan. 9th of that year, it would look as if we received an advance copy or as if it was actually available in the previous year. For a presentation copy the notice in our columns was, as Sir Humphry Rolleston suggests in his preface to the centenary number, not very kind, but we should remember that the Editor of THE LANCET was himself on the point of bringing out week by week under the heading of Hospital Reports just such observations as appear in this volume. For then, as now, a noteworthy feature of *Guy's Hospital Reports* is that the articles represent original work contributed solely to its columns and not printed elsewhere. In fact, as Rolleston remarks, "Archives" would convey better than "Reports" an indication of the contents. In this first volume appeared, for instance, a contribution on the thyroid gland by Wilkinson King and Astley Cooper so fundamental that they would probably have gone on to find the explanation of cretinism had not Cooper been so old and King so delicate. This is Sir William Hale-White's opinion in his article on Thomas Wilkinson King as the father of endocrinology. In the first volume, too, appears the most extensive account published of Bright's disease by the man who gave it his name, and in the second volume, along with further papers by Bright, is one by Addison on the Diagnosis of Pneumonia. In 1836 Hodgkin was still curator of the museum and lecturer on pathology at Guy's, and it was Wilks who proposed the eponym Hodgkin's disease for the enlargement of the lymphatic glands and spleen described by Hodgkin in 1832, and it was Wilks who wrote in the *Reports* many of the articles about Addison's work on disease of the suprarenals which led to his name being attached to it. Many other hospitals followed the example of Guy's in bringing out annual reports. Its near neighbour St. Thomas's, in fact, seems to have been first in the field by a week or two. But none started quite with the splendour of the three names which have made the Guy's school famous, and the *Reports*, now for 15 years issued by Dr. Arthur Hurst, worthily maintain the tradition.

## ANNOTATIONS

## FEVER IN THE TREATMENT OF VENEREAL DISEASE

AMONG the topics discussed at the International Congress of Physical Medicine held in London a fortnight ago was the therapeutic value of artificial fever.<sup>1</sup> Several speakers referred to its beneficial effects in certain forms of syphilis and gonorrhœa, and Dr. W. M. Simpson, who initiated and directs the research in fever therapy at the Miami Valley Hospital, Dayton, Ohio, and is also associated with the United States public health service, made this the subject of his paper. He described the development of the "Kettering hypertherm"—an air-conditioned cabinet of relatively low cost which, in expert hands, combines the merits of safety and efficacy. Since this work began at Dayton 5½ years ago, 431 patients have undergone the treatment, many of them having sustained a temperature of 106°–107° F. for a total of fifty hours or more, and there have been no fatalities. The only complications have been slight burns occurring in a few patients early in the evolution of the method. Dr. Simpson's report deals with 191 sufferers from venereal disease who have received adequate treatment along these lines and have been observed over subsequent periods ranging from 6 months to 5½ years. Excellent and often remarkable results have been obtained in a large proportion of patients with gonorrhœa, of all types and in all stages. The combination of chemotherapy and induced fever in early syphilis has led to rapid clinical and serological improvement, and the available evidence suggests that the two methods combined may bring about cure in a much shorter time than is possible with antisyphilitic drugs alone. Patients with sero-positive primary and secondary syphilis have remained clinically and serologically negative for years, after only thirty weeks' treatment by these means; whereas with chemotherapy alone treatment commonly continues for two years or more. In late syphilis, congenital syphilis, and neurosyphilis the results have been equally encouraging, and the treatment of 27 patients with general paralysis by the combined method resulted in complete clinical remission in 21, while 4 others showed definite improvement. Admittedly the total is small, but within these restricted limits the figures compare favourably with the published results of malarial therapy.

Following the success of early experiments with this method of induced fever, 55 "hypertherms" were supplied to 25 other centres in the United States and at 23 of these the results obtained have been substantially the same. From the quality of the work and the length of time the investigation has been in progress we may say that this form of treatment has now passed beyond the experimental stage. In reviewing some of the results reported from Dr. Simpson's clinic, the Mayo Clinic, and elsewhere—reports strongly suggesting that the method is useful in gonococcal urethritis and in metastatic complications of gonorrhœa—we urged<sup>2</sup> that an investigation of the possibilities of fever therapy as a means of shortening the acute stage of gonorrhœa and preventing complications should now be undertaken by public health authorities in this country, in conjunction with the medical officers of venereal disease treatment centres. The inclusion of all stages of

syphilis within the scope of fever therapy opens a yet wider field for the relief of suffering, the reduction of economic loss, and the saving of public money. It seems possible that we are at the beginning of a beneficent revolution in methods of treatment which are wearisome and often unsatisfactory, and it is to be hoped that those with opportunities of testing these methods fully and impartially will show the necessary spirit of active inquiry.

## HEALTH ORGANISATION ON THE RAND MINES

A CHARACTERISTIC of the native labour force working in the Witwatersrand gold-mines is its instability. The report for the year 1935 of Dr. A. J. Orenstein, chief medical officer of the Central Mining—Rand Mines group, shows that for the mines under his control the average number of natives employed was 99,187; but during the year there were 96,057 recruits, which represents a labour turnover of nearly 97 per cent. Such vast changes complicate the interpretation of the annual death- and sickness-rates, for it has been repeatedly found that new natives are more susceptible to respiratory diseases than the old hands, so that during periods of increased labour supply there is usually observed a rise in these diseases and in meningococcal cerebro-spinal meningitis. Accident-rates appear to be less susceptible to the influx of new labour, a fact which Dr. Orenstein attributes partly to the system of preliminary training in vogue on the mines and to the activities of a Prevention of Accidents committee.

Both the incidence of and the mortality from pneumonia show an increase from 1933 to 1934 and from 1934 to 1935. Towards the end of 1934 an experiment was inaugurated with a mixed anti-pneumonia vaccine at two of the 11 mines on the Rand in the group, every alternate native entering employment at one mine being inoculated and all new recruits at the other being inoculated. At the former the inoculated natives showed a somewhat lower incidence of both lobar and broncho-pneumonia—104 cases amongst 3740 new natives inoculated to 143 cases amongst 3746 uninoculated. At the latter the incidence rose very slightly but the mortality declined. It is clearly too early to draw definite conclusions, but the results are regarded as sufficiently encouraging for the experiment to be continued this year and perhaps extended to further mines. Enteric fever plays an important part in the mortality of natives, constituting 11 per cent. of the total mortality in 1934 and 5 per cent. in 1935. A comparison of the incidence-rate on mines provided with water-borne sewage with that on mines served by night-soil buckets is illuminating. On the former the cases per 1000 employed per annum was 2.65, on the latter 3.99, and it is calculated that if the former rate had prevailed over all the mines there would have been a reduction of 888 cases. In a high proportion of the autopsies performed on natives healed enteric ulcers are found, which suggests a wide prevalence of the disease in the native territories, and probably accounts for its endemicity on the mines. Meningitis occurred on nearly all the mines of the group in 1935, and of the 118 cases nearly 70 per cent. proved fatal. Only 15 cases of hookworm were recorded among the European employees, though it is estimated that at least 10 per cent. of the native labour force are "carriers." Reliance is

<sup>1</sup> THE LANCET, May 23rd, 1936, p. 1201.

<sup>2</sup> *Ibid.*, March 28th, 1936, p. 726.

placed entirely on latrine control and the use of salt which thus appears effectively to prevent transmission to the European miners.

Dr. Orenstein's staff consists of 13 full-time medical officers, 1 research medical officer, 81 subordinate European personnel, 79 female native nurses, and 262 other native personnel, apart from sanitary supervision and ambulance officers employed by the individual mines who come under the indirect supervision of his department. That no pains are spared in enlisting the intelligent coöperation of compound officials is clear from the Notes on Elementary Hygiene, by Dr. Orenstein in collaboration with Mr. A. Gordon, chief health inspector, issued in book form for their use, of which a second edition has just reached us. Introductory remarks on the human body and its requirements and the theory of health and disease are followed by admirable chapters on housing, the disposal of wastes, disinfection and cleanliness, food, kitchen methods, the rat-proofing of buildings, compound inspection, recreation, and finally an elementary account of the common diseases and injuries which includes notes on pneumonia, tuberculosis, enteric, typhus, plague, chicken-pox, hookworm, injuries, and sepsis. Very clear diagrammatic illustrations of buildings and equipment complete a manual which merits more than a local circulation.

#### THE DISADVANTAGES OF TANNIC ACID IN MILD BURNS

THE application of tannic acid is rapidly becoming the stereotyped treatment for burns. In severe burns it has given results in the saving of life and in the prevention of pain and disfigurement far superior to those following any other form of treatment. It is sometimes forgotten, however, that the tanning effects of the solution are not confined to the dead tissues. Dr. Frederic Taylor<sup>1</sup> is concerned about the growing tendency to use tannic acid as a universal application for burns of all degrees of severity. In the second degree burn he thinks that the damage to the delicate layer of the epithelium is a serious consideration. Intact skin is protected by the cornified layer of the epithelium, but when that layer is once destroyed the growing cells responsible for the regeneration of the surface epithelium are at the mercy of the tannic acid and may easily be killed by it. The effect of tannic acid on the skin of rabbits illustrates this point. The rabbit's skin contains no protective cornified layer; tanning extends throughout the surface epithelium and even along the epithelium of the hair follicles. Dr. Taylor's advice is to withhold coagulating applications except in burns of such severity that they are needed to save the life of the patient. Of the coagulating solutions he prefers gentian-violet as being least harmful to the generating epithelium. In all milder burns he advises bland applications such as sodium hypochlorite and ointments, as he regards rapidity of epithelial regeneration as of first importance. The stupidity of causing deep injury to tissues, by drastic treatment carried out to promote healing of a comparatively superficial lesion, is self-evident. There may well be many burns in which the old-fashioned methods yield satisfactory results; but in the rather common type of burn of moderate severity it seems to us that the increased incidence of pain and suppuration, which Dr. Taylor admits to be a disadvantage of treatment by ointments and such like, is a big

price to pay for rapidity of healing. May it not be that the enthusiasm of some surgeons for the tannic acid treatment has carried them too far, and that they are using the solutions too strong and applying them unnecessarily often? After all, if deep destruction of the epithelium results, scarring will follow, and that is one of the sequelæ the treatment is particularly designed to avoid.

#### EARLY AMPUTATION FOR SEVERE INJURY

A FEW months ago we published a paper from Cairo<sup>1</sup> recommending very early amputation for severe crushing injuries of the limbs. An impressive series of cases led Abdelsamie to conclude that these seriously injured patients stand operation quite well, and that the risk of death increases as amputation is delayed. Benajas,<sup>2</sup> on the other hand, is not convinced of the necessity for speedy operation in every case. Its advantages, he considers, are that it anticipates the development of infection and possibly of septicæmia, and so may save life or the unnecessarily extensive sacrifice of tissue; that it prevents shock by removing the source of toxins; and that in cases where the great vessels are destroyed the patient is spared the sufferings and dangers associated with gangrene. Objections, however, are that it is likely to increase traumatic (as contrasted with toxic) shock, and that it carries a risk of removing either too little or too much tissue, whereas with delayed operation a line of demarcation has had time to form and shock and hæmorrhage have been treated. Benajas believes in immediate amputation (1) where infection has already set in and the patient's general condition is bad, (2) where the great vessels are injured and operation is required to check hæmorrhage, and (3) where the principal nerves (especially in the upper limb) are destroyed. He admits that if a patient is seen within the first three hours, before shock has developed, it is best to operate at once, but he maintains that if shock has already set in the operation should be delayed while anti-shock treatment is carried out. This is in direct opposition to the conclusions of Abdelsamie, who has watched two patients die during the interval and would therefore avoid a minute's unnecessary delay. In practice the decision is often made harder because other injuries are present which make one hesitate to attempt operative treatment of any kind. Surgeons will always be divided into two camps, the bold and the cautious, but it seems highly desirable that both types should have a background of information derived from further observations on the "immediate" method.

#### NITROUS OXIDE AND ASPHYXIA NEONATORUM

CONTINUING his valuable studies on the chemistry of the blood of the new-born baby, N. J. Eastman<sup>1</sup> has tried to ascertain whether anæsthetics play a part in the causation of asphyxia neonatorum. Blood samples were obtained from the umbilical artery and vein in a special segment of cord removed immediately after birth, before the delivery of the placenta, and before the onset of respiration. Maternal blood specimens were also taken from the arm vein and radial artery. The blood of forty babies delivered from mothers under anæsthesia was examined in this way. In four cases the anæsthetic was chloroform, in eight ether, and in twenty-eight

<sup>1</sup> Jour. Amer. Med. Assoc., April 4th, 1936, p. 1144.

<sup>1</sup> Abdelsamie, L.: THE LANCET, Jan. 25th, 1936, p. 187.

<sup>2</sup> Benajas, P. C.: Medicina Latina, 1936, ix., 183.

<sup>3</sup> Amer. Jour. Obst. and Gyn., April, 1936, p. 563.

nitrous oxide and oxygen in various proportions; in addition the blood of fifteen infants delivered without anaesthesia was examined as a control. The results show that chloroform anaesthesia has no appreciable effect upon the oxygen saturation of the foetal blood. In the eight cases of open ether anaesthesia there was a slight depression of the average oxygen saturation in the foetus, to about 45 per cent. (It must be borne in mind that while the arterial blood of the mother is usually 95 per cent. saturated with oxygen, the arterial blood going to the foetus at the moment of birth is only about 50 per cent. saturated.) With nitrous oxide greater changes were found; where a gas-oxygen mixture containing 90 per cent. of gas was used for operative interference the oxygen saturation of the foetal blood was only 25 per cent. Previous observations suggest, however, that saturations as low as this are readily withstood by infants at birth, severe asphyxia being usually associated with figures below 10 per cent. Such a state of affairs was reached only when the percentage of nitrous oxide exceeded 90, when it was given for more than five minutes. The practical lessons of Eastman's study are that while weak gas-oxygen mixtures are perfectly satisfactory for inducing analgesia, the stronger mixtures, administered to produce longer periods of true anaesthesia, carry serious risks for the baby. An adequate saturation of the foetal blood with oxygen cannot be guaranteed unless the mother receives 15 parts of oxygen in every 100 parts of the gas mixture. Particularly after a long labour, babies withstand anoxaemia poorly, and if operation is necessary in such cases, ether on an open mask is the anaesthetic of choice, as carrying the least possible risk for the mother and child. The forms of apparatus designed to produce analgesia with "gas and air" do not deliver a strong mixture provided their valves are in working order. But clearly the dangers to the infant arising from high percentages of nitrous oxide must be kept in mind by those who advocate the wider use of this gas in midwifery practice.

#### THE DENTAL TRIBUNAL

THE funds of the General Medical Council have to be carefully husbanded to cover its statutory duties of protecting the public and of ensuring a proper standard of medical education and registration. The Dental Board of the United Kingdom is in a happier position, for after having discharged these obligations the Board has a large surplus available to make dental schools more efficient and to increase the number of their students. This comes about owing to the regulation which requires everyone on the Dentists Register to pay an annual retention fee. At the opening of the thirtieth session of the Board on May 13th Sir Francis Acland expressed his gratification at the prospect that the Board's income would remain for some time on a stable basis. Under a scheme initiated six years ago with the object of attracting young dental practitioners to adopt teaching as a career, nine dental schools have been assisted by contributory grants to establish teaching posts in operative dental surgery, orthodontics, or allied clinical subjects. At the present time the Board is committed to annual grants of £4000 for eight teachers of professorial rank, £2800 for twelve teachers in the demonstrator grade, leaving £8000 a year for bursaries to dental students. During the last two years nearly £7000 has been allotted to four dental schools for new equipment and to one school for new premises. Those who resent the obligation to

pay a retaining fee may at least have the satisfaction of feeling that they have contributed to the advance of dentistry as a scientific study. In some respects, Sir Francis points out, the methods of the Dental Board of the United Kingdom are not as drastic as those of some others. In the Irish Free State the dental board has taken action in the matter of signs and announcements. In the opinion of the Irish board the position of a dentist's premises is sufficiently indicated to persons seeking him by the display of a small name-plate, at the entrance to the premises, bearing the dentist's name and qualifications. Anything in excess of this must at the instruction of the board be removed within ten days. Compare with this Sir Francis Acland's ruling on the question whether dental surgeons should carry long rows of capital letters on their professional plates. To separate the R.C.S. or the R.F.P.S. from the preceding L.D.S. may suggest a double qualification, and the solution that appeals to Sir Francis himself is for the qualification to appear in the form L.D.S. (R.C.S. Eng.). But he does not (at present) suggest that the board should make any regulation on the subject; he is content to add, as his mother's Quaker grandmother used to say to her: "Thee may do as thee likes, but thee knows what I wish."

#### TYPHUS FEVER

To the January-March issue of the *Epidemiological Report* of the Health Section of the League of Nations Dr. Yves Biraud and Dr. S. Deutschman contribute the first part of an elaborate article on the geographical distribution and epidemiology of typhus and typhus-like rickettsia infections. They point out in the first place that after a decade of steady decline the prevalence of typhus has increased in several countries during the last five years. The return of lice-borne typhus, which they attribute partly to disappearance of the population immunised during the war and partly to the prolonged economic depression in rural areas, is not limited to the pandemic focus of eastern Europe, but has also taken place in North and South Africa, South America, and Mexico. The new epidemic wave reached its peak in 1933 in Egypt and China and in 1934 in South Africa and most countries of eastern Europe. In Soviet Russia the number of cases reported rose from 32,035 during the twelve months ending Sept. 30th, 1934, to 66,636 in the following year. The seasonal incidence in Soviet Russia was more irregular than in Poland and Rumania, and reached its maximum earlier than in other countries in eastern Europe. With the exception of Lithuania the Baltic countries were not affected by the disease in 1934 and 1935. In certain districts of Poland there was an increase in typhus in 1935 as compared with the previous years, and a decline or unchanged condition in others. In Czechoslovakia, apart from an isolated case in Slovakia, no case of typhus was reported outside Sub-Carpathian Russia. In the beginning of 1936 there was a substantial increase in the number of cases in Sub-Carpathian Russia, and in March a mild type of disease invaded eastern Slovakia. In Hungary there was a decrease in the sporadic cases reported in 1934-35, whereas in Rumania 1935 was the worst year since 1927. In January, 1936, 572 cases were notified throughout that country, and in February, 1905. The fatality-rate varied between 9.5 and 10.5 per cent. from 1932 to 1935. During 1934 an increase in the number of typhus foci was reported in Bulgaria. Among the other countries in southern Europe Portugal has recently had the greatest number of cases, 104 with

32 deaths having been reported in 1934-35. As regards the countries of North Africa an increase in endemo-sporadicity occurred in 1935 in Algeria, Tunisia, and Morocco, whereas in Egypt the situation was better in 1935 than in the two previous years. The rest of the article will deal with the distribution of the tick-borne diseases variously known as benign summer dermatophus, exanthematous fever, or boutonneuse fever throughout the Mediterranean basin, and of murine typhus in various European countries.

#### SIR CHARLES KENDERDINE

THE death on Monday last at Lewes of Sir Charles Halstaff Kenderdine removes one whose services rendered to the victims of the European war were of outstanding value. A well-known land agent, he was at the outbreak of war secretary of the Land Union, but when the disabled soldiers and sailors began to reach home he became the leading spirit in the care and treatment of thousands of badly mutilated men. He was director of the artificial limb supplies and chairman of the advisory council on artificial limbs at the Ministry of Pensions from 1917-20; the light metal limbs which were soon devised were a substantial improvement on anything previously in use, while great attention was paid to standardising the construction of limbs. The restoration to conditions approaching normal life of many who would previously have been doomed to hopeless crippledom was frequent and the good results of the work cannot be exaggerated. When Queen Mary's Hospital at Roehampton was established for the reception of mutilated sailors, soldiers, and airmen, Sir Charles was the main instrument in raising through public subscription sufficient money to buy Roehampton House, where the beneficent work was later extended to the civilian as well as the military disabled. Sir Charles, who was created K.B.E. in 1918, was also one of the founders of the Queen's Hospital at Sidcup where facial injuries received during the war were treated, often with sensational results. The hospital is now a convalescent centre under the dispensation of the London County Council;

#### SILICOSIS IN SOUTH WALES

THE recent appointment of Prof. T. David Jones, Ph.D., as professor of mining in the University College of South Wales and Monmouthshire, is of interest to many members of the medical profession because of Prof. Jones's long association with the late Dr. J. S. Haldane, F.R.S., in work relating to industrial risks in the various mining industries. Prof. Jones has taken an early opportunity of urging mining engineers throughout the South Wales coalfield to pay more attention to the problem of silicosis—a problem whose final solution necessarily demands coöperation between workers trained in very different fields of science, medical, engineering, chemical, and geological. His lecture on silicosis in the South Wales coalfield, given at the South Wales Institute of Engineers on May 14th, was one of three addresses in which he proposes to cover the different aspects of silicosis and allied dust diseases in this area. While fully admitting the importance of what he called classical silicosis in coal-miners engaged in special work involving exposure to the dust of hard stone, hard heading workings, borers, and sinkers, he suggested that among those accepted for compensation by official bodies there were a proportion that might be described as "official"

silicosis, in which the type of disease failed to conform to the classical description, and whose exact nature must be held doubtful. Many of these cases, he thinks, are in reality cases of bronchitis, under which name indeed they are usually diagnosed by the doctors in the mining areas; and he made a strong plea for various improvements in mine hygiene, including the protection of miners from exposure to cold in "spakes" in the anthracite field. He also appealed for treatment facilities for early cases of this condition, and suggested that the Welsh National Memorial Association, already equipped for the treatment of tuberculosis, might be a suitable body for this purpose, if the necessary additional expense could be met. While paying a tribute to the conscientious work of the medical officers of the Silicosis Board, he suggested that they might well be given additional facilities in order to clarify the diagnosis in doubtful cases.

Prof. Jones's lecture was followed by a valuable discussion, in which several medical men as well as mining engineers took part. There was general agreement that the silicosis of the South Wales coalfield is a genuine problem complicated to a very great extent by the fact that there is exposure to a combination of dusts, some chemically active, some relatively inert, so that the clinical picture is far less simple than that, for example, presented in the gold-mining industry on the Rand.

#### AN AUSTRALASIAN COLLEGE OF PHYSICIANS

At a meeting held in Melbourne on May 8th and 9th, the Association of Physicians of Australasia agreed to the principle that a College of Physicians should be inaugurated in Australasia. The preliminary steps are now being made to put the resolution into effect. We understand that it is intended to model the new college so far as possible on the pattern of the Royal College of Physicians of London.

THE centenary of the Royal Medical Benevolent Fund is to be celebrated by the Royal Society of Medicine on Wednesday, June 10th, when Dr. Robert Hutchison and Sir Thomas Barlow, the two presidents, will receive guests at an evening reception at the Society's house in Wimpole-street, W.

Sir Thomas Lewis, F.R.S., will deliver the George Alexander Gibson lecture of the Royal College of Physicians of Edinburgh on Monday and Tuesday, June 8th and 9th, at 5 p.m. His subject is Symptoms and Signs of Embolism in the Limbs, with special reference to pain.

OUR last issue contained an announcement that Sir Robert Rait, principal and vice-chancellor of Glasgow University, was retiring on Sept. 30th and would be succeeded by Sir Hector Hetherington. Sir Robert's retirement was due to ill-health, and we regret to record that he died on Monday last in his 63rd year.

THE board of governors of Westminster Hospital have accepted the offer of about £350,000 for the site of the hospital made by the firm of John Laing and Son of Carlisle. A further sum of £250,000 will however be required to complete the rebuilding of the hospital on its new site in Horseferry-road. Messrs. Laing intend to build a block of offices on the old site.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### CII.—PROGNOSIS OF “ENLARGED” TONSILS

TONSILS used to get so big that they obstructed the fauces, leading to defective respiration and to deformity of the chest. They were accompanied by a similar hypertrophy of the other masses of lymphoid tissue of the upper respiratory tract and were associated with the symptoms described as “mucous disease” by Dr. Eustace Smith. In the words of Morell Mackenzie they were the size of walnuts, often of bantam’s eggs and sometimes of hen’s eggs. If one saw such to-day it is probable that the right treatment would be to cut off the redundant tissue by the old operation of tonsillotomy; but it is doubtful whether anyone would have the courage to do it. Actually we do not see them; the whole syndrome has practically disappeared. It is reasonable to argue that all these tonsils were “septic” and that to-day they would have been enucleated before they had become “enlarged.” I do not myself believe that that is so, but that it was a form of reaction of the body to some state of hygiene that no longer exists, just as we no longer see the cases of hypertrophic rhinitis nor advanced cases of atrophic rhinitis, although the big air-way which underlies the last is commoner than it was.

A pertinent question then arises. If the condition for which our laryngological grandparents devised a small operation has disappeared, why do we not only continue to operate upon tonsils, but to perform an operation which is a much greater one than the old? The answer is that we enucleate tonsils because they are “septic,” and by their being septic we mean that there are living in the crypts organisms which are doing harm locally or to the body generally by absorption into the blood stream. Our problem of the prognosis of “enlarged” tonsils becomes then changed to the problem of the prognosis of “septic” tonsils. There is no certain relationship between the two; either a tonsil of moderate size—which would be called “enlarged” to-day by those who do not remember the really big ones—or a small tonsil may be a “septic” one. This altered problem may be approached by considering what would happen if no tonsils were removed. The local harm shows itself by a series of illnesses known as “acute follicular tonsillitis” or as “sore-throats” when described by the patient. When three of these occur in a twelvemonth the removal of tonsils is followed by their cessation. We can therefore say that in such cases tonsillectomy saves the patient further pain and distress, avoids his taking time off duty with the consequent loss of work or of schooling, and perhaps results in some improvement of general health. It is doubtful whether lives are saved thereby; our grandparents did not die from acute follicular tonsillitis nor from the associated quinsies and there is a definite tendency for one to grow out of the former if the tonsils are left alone. It is true that it is only rarely that we see the acute non-suppurative phlegmons that are described in the old books; but it is by no means certain that these and allied conditions such as erysipelas of the throat have anything to do with the tonsils. The last time any quantity of cases was reported was before 1913 when the subject was discussed at the International Congress of Medicine held in London in that year.

### SEPTIC TONSILS

So far as the tonsils which show local evidence of sepsis are concerned therefore the problem is a fairly easy one. We have however often to decide on “sepsis” in tonsils without any evidence of follicular tonsillitis objective or subjective being obtained. This brings up the thorny problem of so-called “focal sepsis.” We can ask the question in one of two ways. How much good do we do by removing tonsils for focal sepsis? or How much harm would come if we left them all? With regard to the first, we can say at once: Undoubtedly one works miracles thereby on occasion.

I can remember three such cases in 17 years:—

The first was a young doctor who for weeks could not rise from his bed for sciatica. There was no evidence that the tonsils were a source of sepsis, but other methods of treatment having failed, Dr. J. A. Ryle said that he thought the tonsils must be removed. This was done under local anaesthesia. Within 48 hours the pain of the sciatica was gone and it never returned. The second was an income-tax inspector with pain in the back which did not keep him from work, but which for years had impaired his efficiency and damaged his temper. Tonsillectomy made a different man of him. The third was a married woman approaching middle age who was crippled with aches and pains without objective signs. Almost as soon as her throat was healed she was able to return to her golf.

In none of these three cases was there any history of tonsillitis or sore-throat; in all of them the tonsils were small and gave no physical signs that would distinguish them from the numerous tonsils removed without any improvement, or from the tonsils seen in persons of the same ages who have no lesions that can be attributed to focal sepsis.

Three such cases in 17 years is a poor return; but it must be remembered that in each case the result changed the meaning of life to the patient. It is this which compels us to go on and to try to find some further guidance in the selection of cases. Where there are tonsils that should come out on pharyngological grounds we are on firm ground. I can add a fourth case from this category.

A young nurse was in danger of having to give up owing to flat-footedness. Profoundly sceptical as to any relation between this and her tonsils, I agreed to remove these owing to the recurring tonsillitis. The flat-footedness at once disappeared, she was able to finish her training and to follow her profession as a nurse.

In the rheumatoid arthritis of the middle-aged woman I believe that the cases in which improvement may result are those in which there is a history of recurring tonsillitis in adolescence or young womanhood; but I must confess to bitter disappointment in the results, hoping at the most that I may have stayed the progress of this cruel disease from time to time. Further improvement in selection must come from the physicians. It is impossible to get from these what organism they suspect. They ask for a report on “focal sepsis,” and when pressed with the question “In relation to what organism?” they fail to reply. When general medicine has advanced to the stage of knowing what type of organism may be causing any given lesion cultivation of the tonsil before and after removal may give some guidance for the future in the decision to operate.

Would harm come if we left all the tonsils other than those that give a clear indication for removal on

pharyngological grounds? So far as the two lethal diseases of childhood—acute rheumatism and nephritis—are concerned, the answer is in the negative. There are still some physicians who demand the removal of tonsils as a routine in these diseases, but as with all rules-of-thumb in clinical medicine this routine is almost certainly a failure.

We may approach our problem once again by asking why there are so many tonsil operations performed? Although the number is now on the down grade they are still too many; and the reason is that this idea of "sepsis" is neither an anatomical nor a pathological entity. There must therefore be a wide divergence of opinion on the value to be laid on different pieces of evidence, general and local, objective and subjective, upon which the decision is made.

Finally, with Hippocrates, we must ask not only what good can be done by removing "septic" tonsils, but what harm can ensue from the removal of tonsils which are not septic? This is an important question in prognosis and, in my opinion, the harm may be of wide range and of varying intensity.

#### ILL-EFFECTS OF DRASTIC REMOVAL

*In children.*—In all children under 5 and perhaps under 8 the removal of tonsils seriously impairs resistance to infection, not of the specific diseases such as diphtheria or measles, but to that general infection which leads to severe sore-throats, colds, being generally "off-colour," and the appearance of diffuse shotty glands in the neck. This particularly results from the type of operation in which the pharynx is practically flayed of lymphoid tissue. The so-called lingual prolongations of the tonsils are removed almost to the midline of the tongue, and in addition a thorough adenoid operation results in all the lymph tissue being removed from the nasopharynx. In the children of the well-to-do not much harm results, nature has provided so many resistances that those remaining are enough to combat such organisms as are met under good conditions of hygiene. Even in these however a deafness of a catarrhal type may occur between the ages of 14 and 16 causing much anxiety to the parent.

In the children of the poor, however, who have to combat a greater degree of sepsis in the Listerian sense varying with the conditions of hygiene under which they live, the results may be very serious and vary from a fading away of the child for no apparent reason to a chronic nasal catarrh which makes it seem that the child is never free from a cold. Removal of tonsils seldom cures recurring colds; it may make them worse. Nor does it cure otitis media, except in rare cases, but what is not generally known is that it is extremely difficult to get well an otitis media that occurs in a tonsillectomised child, especially if the operation has been that which I have called the flaying of the pharynx.

*In the adult* retention of lymph tissue is not so important. There is, however, one condition in which conservation is necessary. It is the person with the large nasal air-way, a large nasopharynx, and an oro-pharynx in which the soft palate, usually a small one, hangs down at an undue distance from the posterior pharyngeal wall. These people complain of "sore-throat" which on inquiry proves to be daily or constantly present. They have large red tonsils as though nature had tried to limit the cross-section of the air-way by their hypertrophy. The removal of these makes the symptoms much worse.

#### SUMMARY

We may sum up by saying that the "enlarged" tonsil no longer exists. It is doubtful whether inflammations of the tonsil ever kill, but the condition of "septic tonsils" causes much ill-health. When this takes the form of recurring tonsillitis the removal of the tonsils will almost certainly cure, but when this indication is not present the results are disappointing, though occasionally miraculous. In the adult not much harm is done by removing unaffected tonsils, but in children—especially among the poor—the damage may be serious and far-reaching, though difficult to assess. The mistake most often made is that of confusing the reaction of the tonsils to a droplet infection with an inflammation arising from organisms residing in the tonsil.

T. B. LAYTON, M.S., F.R.C.S.,  
Surg. in Charge of the Throat and Ear  
Department at Guy's Hospital.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. J. G. Boal to *President* for course.  
Surg. Comdrs. W. A. Hopkins to *Galatea*, and F. B. Quinn to *Victory* for R.N.B.  
Surg. Comdr. (D) A. D. McHaffie to *Barham*.  
Surg. Lt.-Comdrs. T. L. Cleave to *Iron Duke*, and S. Jenkinson to *Excellent*.  
Surg. Lts. F. W. Gayford to *Excellent* and to *Victory* for R.N.B.; D. M. Beaton to *Lucia*; W. J. F. Guild to *Boscawen* for R.N. Hosp., Portland, and for dockyard; S. J. Van Pelt to *President* for three weeks' course and to *Courageous*; and T. J. Harkin, M. G. H. Heugh, L. Merill, E. H. Murchison, and G. A. Maxwell Smith to *Victory* for R.N.B.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. A. S. Pearson to *Curacoa*.

### REGULAR ARMY RESERVE OF OFFICERS

Col. J. W. Langstaff, D.S.O. (late R.A.M.C.), having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

### MILITIA

Lt.-Col. (local Lt.-Col.) R. M. Gorssline, D.S.O., M.B., and Maj. (local Maj.) J. E. Hunter, M.D., of Permt. Active Mila. of Canada, relinquish local rank on ceasing to be empld. on Mil. duty in the United Kingdom.

### ROYAL ARMY MEDICAL CORPS

#### ARMY DENTAL CORPS

Short Service Commissions: J. A. O'Gorman to be Lt. (on prob.).

#### TERRITORIAL ARMY

Majs. W. W. Hallchurch and R. J. W. A. Cushing, T.D., to be Lt.-Cols.  
Capts. J. Cook and R. W. Power to be Majs.  
Lts. B. L. McQuillan and W. N. S. Donaldson to be Capts.  
W. A. Bellamy to be Lt.  
J. R. Hamerton (late Cadet Dulwich Coll. Contgt., Jun. Div., O.T.C.) to be Lt.

### ROYAL AIR FORCE

Flying Offrs. promoted to the rank of Flight Lt.: L. E. A. Dearberg, H. L. Willcox, P. A. Cooper, A. R. C. Young, and R. C. H. Tripp.  
Flight Lts. T. D. L. Bolan to Medical Training Depôt, Halton, and V. D. A. Blackburn to No. 1 School of Technical Training (Apprentices), Halton.  
Flying Offr. R. F. Courtin to Medical Training Depôt, Halton.  
*Dental Branch.*—A. P. Britton and A. J. S. Wilson are granted non-permanent commissions as Flying Offrs. and to Medical Training Depôt, Halton.

#### RESERVE OF AIR FORCE OFFICERS

Flight Lt. N. P. Henderson resigns his commission.

## SPECIAL ARTICLES

MEDICAL TRUANTS<sup>1</sup>

By Lord MOYNIHAN OF LEEDS, M.S. Lond.,  
F.R.C.S. Eng.

CONSULTING SURGEON, LEEDS GENERAL INFIRMARY

[Lord Moynihan reviewed, in an eloquent dissertation, the careers of a number of men who, while medical by profession and occasionally by practice, became more famous for other than medical reasons. Thomas Linacre, in whose honour the lecture is founded, formed a good example, for he was known in his day as classical scholar rather than as physician, in spite of his early connexion with the Royal College of Physicians of London.

The lecturer first reviewed the association in Greece at the dawn of scientific medicine with philosophy and pointed out the additions in anatomy and physiology made by Alexandrian, Roman, and Arabian leaders. The debt to Hippocrates, Galen, and Avicenna being acknowledged, their followers were criticised mainly as recorders; though encyclopædic in their generalisations they preserved the old traditions and discussed every old device and tortured new meanings out of old phrases. "Tyrannous indeed," said the lecturer, "was the control which Hippocrates and Galen exercised for so many centuries; in all that sterile period no new thought is found, no new method, no new experiment, and to deny the authority of Hippocrates and Galen or to dissent from their teaching was not merely heterodox, it was heresy punishable by death itself."

The awakening of learning and with it the growth of medicine came from the great schools of Italy and the leaders of mediæval medicine were subjected to scrutiny in a similarly apt manner, particular attention being drawn to William Gilbert, doctor of medicine of Cambridge University in 1569 and a graduate of Linacre's college. For it was Gilbert who asked, speaking of magnetism, "why should I submit this noble science and this new philosophy to the judgment of men who have taken oath to follow the opinion of others, to the most senseless corruption of the arts, to lettered clowns, grammaticists, sophists, spouters, and the wrong-headed rabble, to be denounced, torn to tatters and heaped with contumely?" Other great medical truants enumerated were Galileo, once a medical student; Galvani, physician and physicist; Robert Boyle, the possessor of an honorary medical degree and the formulator of Boyle's Law; John Locke, physician, philosopher, and theologian; Lower and Mayow, known as experimenters, W. H. Wollaston, a country practitioner whom the lecturer found the most expert chemist and mineralogist of his age; Prout, physician and deliverer of the Goulstonian lectures on the application of chemistry to physiology and the originator of Prout's hypothesis; and the great Thomas Young, a physician to St. George's Hospital, famous for his work in physical optics and as the interpreter of the Rosetta Stone. Woodward, again, the geologist, was a doctor earning a right to practise through a medical degree conferred by the Archbishop of Canterbury which was later confirmed at Cambridge, while another doctor known for his

geological learning was James Hutton, who made the first geological maps. Famous scientific truants also enumerated were Linnaeus, Joseph Hooker, for 20 years director of Kew Gardens, and Thomas Huxley, champion of evolution. He continued:—]

## Truants to Politics

Sir STARR JAMESON (1852–1917), whose name will be forever associated with the Transvaal "raid" in 1895, took the degree of M.D. London in 1877, practised in Kimberley, but entering political life became Member of Parliament for Kimberley in the Cape Legislative Assembly and in 1904 Prime Minister.

One of the greatest truants who ever strayed from medicine to become our only Lord Chancellor was ROBERT BANNATYNE FINLAY, Viscount Finlay (1842–1929). Born at Trinity, near Edinburgh, the eldest of a family of eleven children, he was the son of a medical man, and was destined at once for the profession of his father. He was educated at Edinburgh Academy, where he won almost every prize and where he gained the deserved reputation of an exact and critical classical scholar. His scholarly instinct and the severe mental discipline of his youth served him well at the Bar. His faith in a classical education found expression when as President of the Classical Association he advocated the teaching of Latin conversationally as a living language. He qualified as M.B. at the Edinburgh University. He was active as speaker at the University Debating Society. After qualification he visited Europe and became an accomplished linguist, speaking German, French, Spanish, Italian, and modern Greek. He never practised medicine or his favourite branch surgery, for the reason, I am told, that his hands did not obey the commands of his brain to a degree that gave him satisfaction. He turned to the Bar, and was called to the Middle Temple at the age of 25. He took silk in 1882. His success was immediate and considerable; he owed it to his clearness, good sense and directness of argument. Moreover he looked the part. . . . In December, 1916, on the formation of Mr. Lloyd George's first Government, he became Lord Chancellor, an appointment enthusiastically welcomed by the whole legal profession among whom he had worked for 50 years. Later he became a judge of The Hague Court, and finally, when almost 80 years of age, he was appointed the British Member of the Permanent Court of Arbitration at The Hague, a post for which he possessed every qualification but youth.

WALTER BALTHASAR FOSTER, first Lord Ilkeston (1840–1913), who was the second medical man to be raised to the House of Lords—Lister having been the first—came from the north of Ireland, and attended the same Grammar School in Drogheda which long before had first guided the mind of the Duke of Wellington. Trinity College, Dublin, gave him his degree. He went to Birmingham as Medical Tutor to Queen's College; he was then made Professor of Anatomy and finally was appointed to the medical staff of the Birmingham General Hospital. He quickly distinguished himself in professional circles, acquired a wide practice, and contributed much to the medical and political literature of the day in THE LANCET, upon whose staff he served, and elsewhere. Inspired by Mr. Joseph Chamberlain, the maker of Birmingham's political life, he took active part in civic duties and in 1883 was elected a member of the City Council, where his work for the public health was of great value. He was accomplished as a man of affairs and an excellent speaker. In 1885 he entered Parliament as member for Chester, and at the next election he stood for the Ilkeston division of Derbyshire. He was gradually recognised as a remarkable personality, quick in recognition of faces and in memory of names, and at once on friendly

<sup>1</sup> Excerpt from the Linacre lecture delivered at St. John's College, Cambridge, on May 6th, 1936.

GUILLOTINE

CLEMENCEAU

SUN-YAT-SEN

terms with his constituents. He became Parliamentary Secretary to the Local Government Board, where his energy and his tireless capacity found full scope when an outbreak of cholera was threatened. In 1910 he was raised to the peerage, took the title Ilkeston, and was made an honorary freeman of that town.

A medical truant to politics who considerably enlivened procedure in the House of Commons was CHARLES K. D. TANNER (1850-1901). Son of a physician in Cork, he was educated at Winchester and Queen's College, Cork, whence he graduated in 1872, taking his diplomas in medicine in 1875 and the M.D. of the Royal University of Ireland in 1876. He visited the Schools of Medicine in Paris, Vienna, Berlin, and Leipzig, and on his return home quickly gained hospital and teaching appointments, the due rewards of brilliancy. But politics claimed him for its own. In 1885 he was returned for Mid Cork, and threw himself with amazing fervour into the Nationalist movement. In the House of Commons his combative instincts were rarely allowed to rest. Brilliant, witty, and sometimes unanswerable assaults on the Government greatly amused the House; these, combined with his joy in practical joking at the expense of his opponents, prevented him from receiving the serious attention, his merits fully deserved. In private greatly loved, in political strife both feared and enjoyed for his audacity, truculence, and bitter but witty irony, his death was mourned alike by friend and foe.

[Lord Moynihan then alluded to the facts that the present Prime Minister of Northern Rhodesia,

Mr. Martin Huggins, is F.R.C.S. Eng., and that two of his own contemporaries in medicine in this country, Dr. Christopher Addison and Mr. Walter Elliott, reached cabinet rank. He resumed:—]

In France, medicine has rendered great service to the State. J. P. MARAT (1742-1793) lived for a time in Soho (1766-1777), returning to his native country as Physician to the Guard, thereto appointed by Comte D'Artois, afterwards Charles X. While in England he published two pamphlets—"A Singular Disease of the Eye," and "On the Gleet." Both in England and in France he achieved some fame as practitioner. In 1788 his medical life was over, and his active political life began. In the notoriety of that life his scientific and philosophical knowledge were to be forgotten, the high position his merits had gained to be denied him, and himself to be scoffed at and derided as an ignorant charlatan who had acquired wealth by selling quack remedies. In his later years persecution, misery, and poverty were his lot; he hid in sewers for his safety, and there, it was said, contracted a terrible form of skin disease. Politically he was always in opposition, "der Geist der stets verneint," and was merciless in his bitter condemnation of all who held power. On July 13th, 1793, he was stabbed in his bath by Charlotte Corday.

In medicine we are not unfamiliar with the improper attachment of names to methods or inventions. "Lister's sounds" are not sounds, but metal bougies; they were not invented by Lister but by Syme. Foreign annexations are not unknown; "Basedow's disease" was first described by Graves; and "Mikulicz's operation" first performed by Paul.

STARR JAMESON

LEONARD WOOD

FINLAY

Not the least of these oddities in eponymous nomenclature is concerned with that instrument for decapitation known as the guillotine. JOSEPH IGNACE GUILLOTINE (1738-1814) was a French physician and an ardent humanitarian. He was a very distinguished student, and settled in practice in Paris. To him the Revolution came as the revelation of a new heaven, and it gained his unflinching support. With Chemier and Lavoisier he joined the "Society of 1789," which later affiliated itself to the Jacobins. At the constitutional assembly of which he became a member he proposed that "for all classes capital punishment should be by decapitation." This was unanimously accepted. Venal judges ceased to have power to torture prisoners, for Guillotine had also secured the absolute equality of criminals, irrespective of rank, position, or the nature of their crime; and he had secured also the least painful execution for all condemned to death. Decapitation, hitherto the hereditary privilege of the few, became the right of all condemned to die. He abhorred the association of his name with the instrument of death, devised by an army surgeon, Antoine Louis, and at first known as "la Louissette."

The most romantic life among modern truants from Medicine to Statecraft has perhaps been that of CLEMENCEAU, who was born in Vendée in 1841 and died in 1929. He qualified in 1865. He visited London and the United States, returned to Paris, and shortly after the outbreak of the Franco-Prussian war of 1870, was elected Mayor of Montmartre. His political career had, however, begun many years before, and so long ago as 1862 he was imprisoned for two months for his share in a Republican demonstration. From 1871 to 1893 he sat in the Chamber of Deputies, playing the part of ardent radical, in manner not unlike Joseph Chamberlain and Sir Charles Dilke at the same time in England. They, however, became gradually sobered by age and experience, but Clemenceau suffered no abatement of those wild and virulent methods of opposition which made him so dangerous an antagonist of Gambetta and Ferry, which gave him the nickname of "The Tiger," but which left on the public mind in his earlier years a conviction that so ruthless a destroyer could have no constructive power. In 1893 he lost his seat and for nine years devoted his time to literature, was a protagonist with Zola in the Dreyfus campaign, and his power as journalist was unexcelled. In 1902 he became Senator for the Var and Minister of the Interior, and from 1907 to 1909 was Prime Minister of France. It was felt then that his political career was at an end, but the war came, and on July 22nd, 1917, the French senate heard from his lips a speech which convinced them that the only man capable and energetic enough to lift France from the moral crisis of a dark year was Clemenceau. He proved the Saviour of France and "deserved well of his country."

The first President of the Chinese Republic, SUN-YAT-SEN (1866-1925), was a doctor. He early devoted himself to politics, especially while living in Hong-Kong. He entered the College of Medicine in Hong-Kong in the year of its inauguration, 1887, and in 1892 was its first graduate. For a time he practised in the Portuguese Colony, Macao. He lived however, much abroad, and spent his days in stirring up plots against the Manchu dynasty. A revolution in China broke out on Oct. 10th, 1911, and on Dec. 25th he was elected President of the Chinese Republic, resigning in March, 1912, to Yuan-Shih-Kai, who in 1915 proclaimed himself Emperor. Sun-Yat-Sen returned to China, organised a new rebellion, and led South China against Yuan-Shih-Kai. In 1917 he was appointed Generalissimo of the Canton Government. His efforts to come to friendly understanding with Russia were not without result; and he introduced Russian ideas, military and civil, into China. He died of cancer in 1925.

The greatest colonial administrator America has yet produced, General LEONARD WOOD (1860-1927), was a medical truant. Son of a medical man, he

took to the same profession and qualified at Harvard in 1884. He entered the army as an assistant surgeon and soon saw service in Arizona against Apache bands. He took his share in fighting and gained the rare and coveted "Congressional Medal for Valour." After service under three presidents in Washington, he and Theodore Roosevelt were jointly authorised, when the war with Spain broke out in 1898, to raise and equip a regiment of rough-riders. After the action of Las Guasimas he was promoted Brigadier-General and became Governor of Santiago after its capture. With enormous energy and with a passion for patriotic service, he civilised the whole province. He then became Governor-General of Cuba. Administratively, and especially in connexion with medical problems, his success was immense. He brought order out of chaos, and his elimination of yellow fever from the island was the model for the later stupendous work of Gorgas at the Panama Canal. His work made possible the creation of the Republic of Cuba in 1912. He owed his success to unbounded energy, determination, common sense, and a high personal character; he had studied not without profit much of the history of recent British colonial administration. When his old colleague Theodore Roosevelt became President of the United States, he conferred upon Leonard Wood the most difficult post he had to bestow. This was the military governorship of the Moro province of the Philippines. Before taking this post he had visited Germany, and had made friendship with Lord Roberts. These two were convinced of the threat of Germany to the world, and they agreed that "Peace could be preserved only by the power to preserve it." Until 1905 he remained Governor of Moro, and by his labours there he turned over the government of the province to his successor when "law and order, and a strong and stable government" had been established. He became chief of the General Staff in 1910. In the States he played the same part as Lord Roberts did in England. He sought to raise enthusiasm for military preparation against the world crisis he felt to be impending. But, like Roberts, his preaching raised little response. After the outbreak of war in August, 1914, he strove with endless vigour and enthusiasm to equip America for the share that he realised she must take. But in search of active participation he was elbowed into the background and only towards the end of 1917 was he allowed to visit France. He was wounded in 1918, and returned to Washington. Democrats in power did little to help this great Republican. After the war he became Governor-General of the Philippines in 1921. Though he sought to educate the people in the principles of popular democratic government and to bring them more and more into a share of the administration, he was tenacious in his belief of the necessity of American sovereignty. He died with his work unfinished in 1927; and since his death his reputation as the greatest of American colonial administrators has become unassailable.

A distinguished truant from medicine to politics was Sir HILARION MARCUS FERNANDO of Ceylon. After a most successful career at the Royal College, Colombo, he came to England to study medicine. At University College Hospital his career was one of uninterrupted success which culminated in his winning the scholarship and gold medal at his M.B. Lond. examination. On returning to Ceylon his brilliant academic success was recognised by his appointment to the staff of the General Hospital, Colombo, but at the height of medical success he suddenly played truant to medicine, took to a political life, and greatly distinguished himself in works connected with agriculture in the island and with economics. He died early in the year 1936.

#### Truants to Literature

Many truants from medicine have escaped to literature; but not a few of those who remained

faithful have adorned the pages of English letters with prose hardly excelled in beauty or pregnancy of meaning by other writers. Among such men my old teacher, Clifford Allbutt, was perhaps supreme among physicians, as was Sir James Paget, greatest of our orators, among surgeons. But they were by no means the first.

Though I may be omitting poets worthy of mention, first of whom was Empedocles (500 B.C.), let me begin the story of authors who were truant with FRANCOIS RABELAIS (1483?-1553), born in Touraine. He became a monk to please his father, and joined the Benedictine Order from which, however, he resigned after punishment for indecorous behaviour. When 47 years of age he studied medicine at Montpellier and later practised at Lyons, taking a doctor's degree in 1537. In later life he returned to the Church and became Rector of Meudon. His most famous work, still widely and appreciatively read, was "The Lives, Heroic Deeds and Sayings of Gargantua and Pantagruel," an extravagant, but despite its grave blemishes and coarseness, a delightful satire on monks, priests, popes, and pedants. The obscenity and absurdity are blended with learning, wit, and humour. As priest he was exemplary in many respects, devoted to the welfare of his flock, beloved by children and generous to all, especially to those in need. His house was the resort of the learned.

JULIUS CÆSAR SCALIGER (1484-1558), the distinguished classical scholar, was also in the ranks of medicine. Born on Lake Garda, he became page to the Emperor Maximilian whom he served in war and peace for 17 years. It was only on leaving the army at the age of 40 that he applied himself to the study of medicine, and not less to the acquisition of languages. His first work "A Defence of Cicero," was prompted by the "Ciceronianus" of Erasmus, wherein the Latin author was harshly ridiculed. His invective against Erasmus stirred the whole world of learning. His erudition was considerable, but his vanity and insolence greatly lessened the high esteem in which otherwise he would have been held by all contemporary scholars.

THOMAS LODGE (1558-1625) had one of the most interesting and varied careers of mediæval times, and may be regarded as a truant in the opposite direction—from a life of endless variety and thrilling incident to medicine. Second son of Sir Thomas Lodge, Lord Mayor of London in 1562, member of a family dating from the reign of Henry I., he graduated at Oxford in 1577, having already written verses. He early abandoned law for literature, and was soon welcomed as companion by Drayton, Lyly, and Watson. His vagaries seem to have alienated the affections of his family and his name was omitted from his father's will. He has been described as one who was "hunted by the heavy hand of God and became little better than a vagrant, looser than liberty, lighter than vanity itself." His early life indeed was marked by continuous unrest and perpetual unhappiness, though he was prodigal with his pen, which was often rancorous. In 1588 and again in 1591 he went to sea, travelling to South America and visiting among other places, Santos and its then famous library. On his return he published more verse referring to the sea. In later years he earned a measure of public approval and support, and is said to have won the commendation of Spenser. After 1595 he wrote only a few volumes of prose. He began the study of medicine in 1596 and took a degree at Avignon in 1600 and at Oxford two years later. In 1599, when the plague raged in London, he wrote "A Treatise on the Plague." In 1609 he is mentioned in a list of the chief physicians of the day. It is, however, as lyric poet that Lodge is most worthy of remembrance, and he is described by a contemporary as a writer of "those pretty old songs and madrigals which are very much the strain of these times"; his lyrics, indeed, are still regarded as among the finest in our language, though it is admitted that he owes much to the French author, Desportes, and something to Ronsard. Sir Humphry Rolleston

says that the most interesting of his plays is "Rosalynde: Euphues Golden Legacy," 1590, which provided young Shakespeare, who was then but 26, with the plot of "As You Like It."

Supreme among all truants must surely be Sir THOMAS BROWNE, of Halifax and Norwich, whose "Religio Medici" continues to be the delight and inspiration to an endless host of his successors. Sir Thomas Browne (1605-1682) was educated at Winchester and Oxford. He practised for a time in Oxford but soon left for the Continent, visiting Montpellier and Padua, and at the age of 28 was given the degree of M.D. at Leyden. On his return he began practice at Shibden Hall, near Halifax, which still stands. After a few years he left Yorkshire for Norwich, and then took his degree of M.D. at Oxford in 1637. He quickly gained high repute as a physician. In 1641 he married and despite his opinion that the act of coition was "the foolishest act a wise man commits in all his life, nor is there anything that will more deject his cooled imagination than to reflect upon the folly he hath committed," he became the father of ten children. The most famous of all his books "Religio Medici" was published surreptitiously in 1635. It was written while he was in Yorkshire, for the occupation of his leisureable hours and for his private exercise and satisfaction, at the age of 30. It suffered from the premature publication of unauthorised versions of which there is nevertheless evidence that the author was not unaware. Sir Thomas, like other great men, believed in the influence of the stars upon the affairs of men, and he held this as explaining the fact that "he was not disposed for the mirth and galliardise of company." Perhaps the most learned of Sir Thomas's work was "Pseudodoxia Epidemica." Its compilation was the work of many years, and the scholarship and research therein contained are remarkable. The reader of to-day will smile as he realises the extent to which Satan is here reproving sin, for credulity was the inherent weakness of a great mind. He believed in astrology, alchemy, witchcraft, and magic, and his faith in the Ptolemaic system of astronomy was unshakable. He showed his credulity when in a trial for witchcraft he was asked by the presiding judge to give his opinion of the case, he said: "That the fits were natural, heightened by the devil's cooperating with the malice of the witches at whose instances he did the villainies"; an opinion which did much to secure conviction. He regretted that in his professional works he had no time to make "those infallible experiments and those assured determinations which the subject sometimes requireth." His reputation for wide and remote knowledge spread throughout the land, and his opinion and guidance were sought by men themselves learned in philosophy, in natural history, and in medicine. He wrote upon "Urn burial," and made it an occasion for quoting Dante. Sir Thomas Browne received a knighthood when Charles II. visited Norwich, after the refusal of the Mayor for whom the honour was first considered.

Sir RICHARD BLACKMORE (1650-1729) took a degree in Arts at Oxford and in Medicine at Padua. His philosophical poem "The Creation" was praised by Addison. His poems were written as he travelled on his rounds. He said:—

"In leisure hours in epic song he deals,  
Writes to the rumbling of his coach's wheels."

Physician to William III. and afterwards to Queen Anne, he is chiefly remembered for the distinction of those who attacked him, among them being Dryden and Sir S. Garth. Colonel Coddington wrote:—

"By nature formed, by want a pedant made,  
Blackmore at first set up the Whipping trade.  
Next quack commenced: then fierce with pride he swore  
That toothache, gripes, corns should be no more.  
In vain his drugs as well as birch he tried  
His boys grew blockheads, and his patients died."

Of medical men who for a time strayed into other paths, we may recall THOMAS DOVER (1660-1742),

inventor of the eponymous powder. In younger days he sailed from Bristol in a privateer commanded by a man of parts, William Dampier, captain in the Navy, hydrographer, buccaneer, to whom he was second in command. We owe to him the discovery of the original castaway, Defoe's model for Robinson Crusoe. The powder which bears his name is in high repute even to this day. He was known colloquially as the "quicksilver doctor," because of his faith in the use of mercury.

Sir SAMUEL GARTH, a Yorkshireman, though never wholly truant (1661-1719), was of high repute in his day, both as physician and as poet. "Dispensary, a Poem," published in 1699, certainly led to the creation of these invaluable institutions for the poor. He delivered the Goulstonian lectures in 1694 and in 1697 the Harveian oration at the Royal College of Physicians. He obtained permission from the College for the body of Dryden to lie there before burial, and he delivered a Latin oration over it. He enjoyed a large practice, held office at the Court, and was, Pope said, the "best natured of men." His couplet in the "Dispensary" is of all his work the best worth remembering :

"To die is landing on some distant shore  
Where tempests never beat nor billows roar."

Later, we claim JOHN ARBUTHNOT, F.R.S. (1667-1735), an Aberdonian, a graduate of St. Andrew's physician and wit, a man whose extraordinary ability was hailed by Pope. By good fortune he was present at Epsom when Prince George of Denmark was taken suddenly ill. He became physician to Queen Anne, and, Swift says, was her "favourite physician." He attended her on her death bed. He gave the Harveian oration in 1727. Fifteen years earlier he published "Law in a Bottomless Pit, or the History of John Bull"; and it is probable that therein he created our national character and name. He contributed to the "Memoirs of Martinus Scriblerus" of which Pope was editor.

MARK AKENSIDE (1721-1770), poet and physician, after little success as practitioner in the provinces, went to Hampshire, and then to Bloomsbury-square, financed by an old friend, Jeremiah Dyson, until prosperity came to him. While still in Newcastle he wrote "The Pleasures of the Imagination," a poem that did not lack success; and was, indeed, claimed as his own by a charlatan, Rolt. It bears Akenside's name only on the second edition. His most famous poem, however, is "Hymn to the Naiads." He became F.R.S. and M.D. Camb. in 1735, and in 1755 delivered the Goulstonian lectures at the Royal College of Physicians, and in 1756 the Croonian lectures. He died on the bed on which Milton had died, having kept silence as poet during the days of his large practice. His name was originally spelt Akinside, but it was soon realised that its sound was unfortunate for one practising medicine, and a change was made. He was satirised in "Peregrine Pickle," by Smollett, a famous truant.

TOBIAS GEORGE SMOLLETT (1721-1771) studied at the University of Glasgow and was there apprenticed to a surgeon. At the age of 18 he sought his fortune in England, and brought with him a tragedy "The Regicide," the very worst effort of his pen. The failure of this wretched play became a stock grievance throughout his life; he was, indeed, reduced to starvation until by influence he obtained the post of surgeon's mate on H.M.S. *Cumberland*, sent to attack Cartagena. In "Roderick Random," licentious though it is, he has left an historic account of the miseries endured by sailors and soldiers alike in that campaign. On his return he began practice in Downing-street, and "attracted more attention as a wit than as a leech," but he had an important share in the revision of Smellie's "Midwifery," the standard book of that time. In 1750 he took the degree of M.D. at Aberdeen, and a year later published "Peregrine Pickle." Like its predecessor, it has no plot; and is merely a string of adventures loosely held together, but the wealth

of amusing incident and the rapidly moving crowd of eccentric figures atone for much coarseness. Two years later he abandoned medicine for literature, and acquired fame and a fortune which he lavishly squandered. Hume likened him to a cocoa-nut—"rough outside, but full of human kindness within." His powers of observation and brilliancy of description have rarely been equalled in imaginative literature.

Best-known and perhaps best-beloved of all literary truants is OLIVER GOLDSMITH (1728-1774). There is, however, some doubt as to whether Goldsmith was ever justified in describing himself as doctor. Admission to the church, the calling of his father and brother, being refused, he was then intended for the law. He was financed by a generous uncle with the sum of £50, lost at once in a gaming house. A little money was collected for him, and at the age of 24 he became a student at Edinburgh, spending 18 months in the acquisition of some knowledge of chemistry and biology. From there he drifted to Leyden where he remained for more than a year leaving with little knowledge of medicine, with only the clothes he wore and a flute. He wandered through France, Switzerland, and Italy, living on charity, casual gifts, and the frequent support given by monasteries:—

"Remote, unfriended, melancholy, slow  
Or by the lazy Scheldt or wandering Po  
My fortune leads to traverse realms alone  
And find no spot of all the world my own."

In 1756 he returned to England, penniless, friendless, with a medical degree obtained somewhere, and attested only by his own unsupported statement. He practised for a time in Bankside, Southwark, as physician to the poor. Amongst his patients was a printer's workman through whose influence with Samuel Richardson Goldsmith was appointed corrector to the press in Salisbury-court. To earn a pittance he later became usher in a school, and afterwards obtained a medical appointment with the East India Company, which subsequently revoked it. He presented himself then for examination for the post of "mate" to a hospital; but even for this humble post he was rejected. Turning to literature for a pittance he found immortality. His farce "She Stoops to Conquer," is incomparable. The "Vicar of Wakefield" will be read so long as our language lasts. His poems, his plays, indeed all his writings, show simplicity and austerity, with an engaging beauty. He was friend, if often the butt of Johnson, Garrick, Reynolds, Burke, and others. The contrast between his written and spoken word is a puzzle to all. Garrick wrote of him:—

"Here lies Nolly Goldsmith, for shortness called Noll,  
Who wrote like an angel, but talked like poor Poll."

But his companionship meant much to great men. When he died Burke burst into tears, and Reynolds laid aside his brush for many days. It was supposed that his death was hastened by indiscriminate attachment to James's powder.

### Other Famous Truants

[Among other truants to literature of whom the lecturer discoursed we find the names of Edward Jenner, the discoverer of vaccination, alluded to as "in a very minor sense a poet"; George Crabbe "of all men truant from medicine professionally the most incompetent," but described by Byron as "Nature's sternest painter yet the best"; the famous German poet Schiller; Keats, "One whose instincts and faculties were more finely poetical than those of any of his contemporaries which included Byron, Scott, and Wordsworth"; Peter Mark Roget, author of the "Thesaurus"; John Brown of the delightful "Horæ Subsecivæ"; Sir Henry Thompson, surgeon, artist, and novelist; Conan Doyle; Robert Bridges, who retired from practice

at the age of 37 to become later Poet Laureate; Ronald Ross, of malaria fame, who wrote poetry, prose, and mathematical exercises; Oliver Wendell Holmes; Weir Mitchell; Sir Francis Seymour Haden, the famous etcher. Other medical truants described included the explorers Mungo Park and Livingstone, and Henry Jones, who as "Cavendish" was the supreme authority on whist. Lord Moynihan concluded:—]

I have given a brief and imperfect record of some of the truants from medicine who have helped to create or develop our own or other branches of science, who have been greatly distinguished in law, literature, or elsewhere. Their careers illustrate the influence of scientific training upon all mental activity, no matter in what field it may be expended. The habits early inculcated of acute and accurate observation, orderly and relevant arrangement of thought, close criticism of every stage in the manifold processes leading to judgment and decision, conciseness in final expression, and impeccable intellectual integrity throughout are for many of us acquired with infinite difficulty, but, once made our own, may be worn with natural ease and appear almost automatic. A scientific training is useful, not only in the work of an arduous and scientific profession, but in all other callings into which by accident or deliberate intention a man may chance to wander.

## BUCHAREST

(FROM OUR OWN CORRESPONDENT)

### JUVENILES AND THE LAW

THE new penal code, to be issued shortly, is very liberal to juveniles. Those under 14 are regarded as children and cannot be held responsible for their misdeeds. Adolescents between 14 and 19 can be blamed only if there is evidence of their being possessed of full powers of judgment when committing the offence. If they are not held responsible, the authorities, after a preliminary study of the circumstances, may resort to the following measures: They may first instruct the family to exert greater supervision, or the director of the school may be asked to apply discipline. If there are no parents, or if they are unsuitable, supervision is entrusted to other relatives. In their absence the child may be placed in charge of another reliable person or of a suitable institution. If neither of these is possible the adolescent is sent into a reformatory. These measures hold good not only up to the age of 19 but to the end of the twenty-first year. Abnormal, weak-minded, and sick juveniles can be treated in special institutions. If the adolescent was fully capable of judgment when committing the crime, as a safety measure he is kept under supervision or sent into a reformatory, or as a punishment he may be publicly reprimanded and sentenced to light imprisonment. Supervision is for one year, and if the youth does not improve during this time he may be sent to a reformatory or sentenced to light imprisonment. With good conduct the board of the reformatory may release him on probation for two years, after which he is entirely free; cases of bad conduct are kept in the reformatory until the twenty-first year. Terms of imprisonment for felony are from 3 to 15 years, and for misdemeanour half the adult sentences, with a maximum of 3 years. Subjects under 16 cannot be sentenced to more than

10 years. They are placed in special institutions. After two-thirds of the sentence, they may be discharged with conditional liberty, but after release from gaol a juvenile may be sent to a reformatory until he becomes of age. The care of those released is in the hands of a society.

### LAYMEN AND THE DIRECTION OF MEDICAL AFFAIRS

Some paragraphs of the new law on public administration allow the magistrates to interfere in organisation of public health institutions. It is obvious that this intervention would harm the normal progress of public health institutions. On the other hand, the new law does not stipulate that the administrative magistrates should hear the opinion of their medical advisers before bringing in any public health measure. This induced the Medical Association to make representations to the Prime Minister, the Minister of Public Health, and the Speaker of the Chamber of Deputies requesting, first, that in questions of public interest the health officer should be consulted, and that he shall have a place on all councils where questions relating to public health and hygiene are discussed. Secondly, that the medical officers, who through the new law are subordinated to the county prefect, should remain, as hitherto, under the control of the Ministry of Health; although the new law empowers the prefects to supervise medical institutions, they are not competent to decide medical questions. Thirdly, the local chief constable may be able to instruct the physician at best to hold lectures of public health interest, but he cannot give instructions in any other direction, having no qualification in matters of public health.

### MEDICAL REFORMS IN ALBANIA

In the post-war years public health in general and the competency of physicians in particular have advanced a great deal in Albania. The State is granting a great number of scholarships for medical students to study abroad, so that on their return they may introduce Western advances. The latest achievement is a new Bill that lays down rules and regulations for medical practice and establishes a medical chamber. Hitherto quacks and magicians could practise in Albania to their hearts' content, but the new law will apply very strict measures against them. According to the Bill foreign physicians may practise in Albania only with the Government's permission, which is given only in exceptional cases, because the country is amply supplied with its own doctors.

Prof. Pierre Duval, of the University of Paris, whose specialty is gastro-intestinal surgery, radiology of the digestive tract, and war surgery, was a guest of the University of Bucharest for eight days, and during this time he delivered several addresses.

On the initiative of Dr. M. Liviu Popovici, professor of pediatrics at the University of Cluj, capital of Transylvania, a new society has been formed for the furtherance of pediatrics. It intends to hold public lectures to enlighten the public on the education, for instance, of nervous and mentally deficient children. The first president of the society, which has 40 members, is Prof. Popovici. It intends to publish a quarterly bulletin.

The International Society for Medical History has elected Dr. Victor Gomoiu, the founder of the Rumanian Medical History Society, as president for the next five years.

## OBITUARY

### JOSEPH DANIEL McFEELY, F.R.C.S.I., D.P.H.

THE death occurred at Woolton on May 15th of Dr. Daniel McFeely who had much important medical work to his credit first in Ireland and for the last 30 years in Liverpool. He was born in Londonderry, the son of a Londonderry merchant, and educated at the Letterkenny High School, at Trinity College, Dublin, and the Catholic University, Dublin. He obtained the Irish double diploma in 1885, and was for a time resident surgeon in the Jervis-street Hospital, Dublin, and later civil surgeon at the Military Hospital, Cork. In 1896 he became F.R.C.S.I., took the public health diploma, and was appointed coroner and medical officer of health for County Donegal. He was also appointed surgeon to the Mercer's Hospital, a post which he filled for seven years. At the Royal College of Surgeons in Ireland he was a member of the council and of the court of examiners, while to his other appointments he at one time added that of assistant surgeon to the National Maternity Hospital. In 1904 he removed to Liverpool, where he was appointed visiting surgeon at the Mill-road Infirmary and carried on a considerable private practice with headquarters in Shaw-street. Among his other activities he worked as emigration officer to the Catholic Emigration Association in respect of children emigrating to Canada. He contributed occasionally to medical journals and wrote an interesting little book composed of his reminiscences as a practitioner. At the close of his life Dr. McFeely lost his sight, and latterly had resided at Holly House, Woolton, where he died. Dr. McFeely married Sarah, daughter of the late J. C. Lenon, and leaves four sons.

### JOHN HERBERT GODSON, M.B. Camb., D.P.H.

Dr. John Godson, who died early in the month, was very well known in the Cheadle district where he was born and where the family had a large professional connexion. He was the second son of the late Dr. Alfred Godson, and had two brothers, medical men. He was educated at Aldenham and Cambridge, and graduated as M.B., B.Chir. in 1893, completing his medical training at Guy's Hospital. There he was resident obstetrician, while he also held posts at the Great Ormond-street Children's Hospital and the East London Children's Hospital. He then joined his father in practice, whom he succeeded as medical officer of health for the Cheadle and Gatley urban district, a post which he held until just before his death. Dr. Godson was prominent in the promotion of the social activities of the neighbourhood; he was a keen churchman, a trustee of the literary institute, and a supporter of the local athletic clubs. He was 69 years of age.

### THEODORE FRANCIS DILLON, M.B. R.U.I.

Dr. Theodore Dillon, who died recently in Cardiff, was educated at Black Rock College, Dublin, and Queen's College, Cork, where he graduated as M.B., B.Ch. in 1898. He was holding a medical appointment at the Ophthalmic Hospital in Cork when he entered the Army Medical Corps to serve in the Boer war. Later he went into general practice in Cardiff where he practised in partnership with the late Dr. Cantillon for over 30 years. He received a commission in the R.A.M.C. during the European war,

and served in France and Gallipoli. Dr. Dillon was a devout Catholic and deeply interested in the affairs of his church, and was also vice-president of the local branch of the Ancient Order of Hibernians. He was 64 years old at the time of his death.

### HENRY JOHN MACKESON WYLLYS, F.R.C.S. Edin.

Dr. Mackeson Wyllys, who died at his residence in Yarmouth on May 11th, was a prominent member of the local medical profession, the son of the late Dr. Wyllys of Yarmouth and brother of Dr. William Wyllys of that town. He received his medical training in Glasgow, and on qualification was for a time house surgeon at the Norfolk and Norwich Hospital. In 1906, on the retirement of his father, he went into partnership with his brother in Yarmouth, where in due course he held a number of professional appointments. He became senior surgeon to the Yarmouth Hospital, and was a life member of the committee of governors and chairman of the nursing committee. He was an honorary member of the Eastern Counties Convalescent Home for Children, and in addition to his professional relations was well known in the town for his support of the cricket club. He was also a noticeable figure for his reluctance to give up the horse and gig for the motor-car. Dr. Wyllys married Miss Ballance, sister of the late Sir Charles and late Sir Hamilton Ballance, and his son is a prominent cricketer.

### MOSES UMANSKI, M.D. Berne, L.S.A.

Dr. Moses Umanski, who died in London recently, was a Russian, the son of Jacob Umanski, and was born in 1862 at Ekaterinoslav and educated in the University of Kharkoff and in Berne and Berlin. He graduated in medicine at Berne and took the diploma of medicine at the University of Kharkoff in 1886 and shortly afterwards came to England. He qualified as L.S.A. Lond. in 1895 and settled in Leeds where he was medical officer to the Jewish Sick Charity and various friendly societies, medical officer to the Leeds Jewish Maternity Charity, and medical superintendent of the Herzl-Moser Memorial Home, for the dying, a post he held for 20 years, from the foundation of the institution. He spent the last ten years of his life in London, where he won the regard of many by his amiable qualities. He was a great champion of the Zionist movement.

### PAUL POWER, M.B. N.U.I.

THE sudden death is announced of Dr. Paul Power, late secretary of the International Medical Agency, Bedford-street, W.C. Dr. Power was born at Tulla, Co. Clare, and educated at St. Mungo's College, from whence he entered the University of Dublin and graduated as M.B., B.Ch., B.A.O. in October, 1928. He volunteered for service in Abyssinia shortly after the outbreak of hostilities and was attached to the British Red Cross unit. He was at Diredawa for a considerable period, and was presented to the Emperor who heartily thanked him for his services. His death occurred from malaria at Aden, while homeward bound. He was only 33 years of age and had fine prospects in practice before him.

## CORRESPONDENCE

## INFLAMMABLE DRESSINGS

*To the Editor of THE LANCET*

SIR,—My council has asked me to report a case it recently considered which appears to contain a significant pointer to members of the profession engaged in general and surgical practice. A patient sustained a slight injury as a result of the puncture of one of his fingers by a chicken bone. This was followed by cellulitis which required frequent and regular dressing. These dressings produced, as they commonly do, a sodden condition of the tissues which our member thought would be corrected by application of a spirit dressing. He accordingly applied a spirit dressing and asked the patient to return within 48 hours for a further inspection of the infected part. The patient had no sooner left the surgery than he attempted to light a cigarette. The dressing is said to have "blown up," and he quickly returned, holding aloft a hand which resembled a flaming torch. Our member dealt with the situation promptly and efficiently and provided the necessary treatment.

It is to be noted, incidentally, that the settlement of this case involved the Medical Defence Union in the expenditure of a considerable sum of money. The moral to be drawn from the foregoing unfortunate experience is that patients who receive spirit dressings should be warned of the dangers of flame or fire of any kind which is likely to ignite the dressing and thereby cause grievous damage.

I am, Sir, yours faithfully,

ROBT. FORBES,

Secretary, Medical Defence Union.

49, Bedford-square, London, W.C., May 25th.

## MENTAL SICKNESS AND CERTIFICATION

*To the Editor of THE LANCET*

SIR,—I appreciate that, as Dr. Rees informs us in your issue of May 23rd, it is the intention of the Institute of Medical Psychology to receive only psychoneurotic cases for treatment, but that does not dispose of the point I raised. The law makes no distinction between psychoneurotic and psychotic cases. Patients who are certifiable, even if diagnosed psychoneurotic, are subject to the legal complications mentioned in my previous letter.

I am, Sir, yours faithfully,

Wimpole-street, W., May 23rd. FREDERICK DILLON.

## VISITS TO RUSSIA

*To the Editor of THE LANCET*

SIR,—It will, we feel sure, be of interest to your readers to know that special arrangements are being made, by the Society for Cultural Relations, to enable doctors and surgeons to carry out a study of the medical services in Soviet Russia. As is probably well known, the Russian health services are organised on a different basis from those in this country. Competent observers have expressed the opinion that the results achieved are worthy of notice. Sir Arthur Newsholme and John A. Kingsbury, for instance, state in their book "Red Medicine," that Soviet Russia "has removed the doctor almost entirely from the field of monetary competition, and has thus abolished a chief source of inadequate medical service."

It is proposed that groups should leave London on June 20th and July 25th for three or four weeks. The programme will give ample opportunity for

studying the organisation of the medical services as a whole, and in addition facilities will be given to enable individual members of the groups to investigate the research and practical work being done in the particular branches of medicine in which they are themselves specialists. Full details of the arrangements can be obtained from the Secretary, S.C.R., 3, Bedford-place, W.C.1.

We are, Sir, yours faithfully,

SOMERVILLE HASTINGS,

JULIAN S. HUXLEY,

J. R. MARRACK.

May 20th.

## SELENIUM TREATMENT OF CANCER

*To the Editor of THE LANCET*

SIR,—The report from the Royal Cancer Hospital on the selenide treatment of cancer in your issue of May 23rd demands some comment. When I received a typed copy in February of this year I returned the following reply: "It is considered highly regrettable that errors of prime importance were allowed to persist throughout the series." I pointed out these errors to the Bristol Royal Infirmary Cancer Committee; in the interest of cancer therapy it is considered desirable that they should be more widely circulated.

The Cancer Hospital sent to Bristol a youngish woman graduate, of the house-physician standing, for a short period to learn what she could about the method. Every facility was given her to learn, and errors of capital importance, such as immediate reaction and rigors after injection, were carefully stressed. The X ray dosage was taught as well as was possible to her and to Prof. Morison who was only available for a few minutes. No communication or request for guidance was made during the "trial."

The report states that the initial dose of S.Se. was 0.5 to 1 c.cm., that increments were of the same amount and that immediate reaction, or rigors, occurred every time it was given. The initial dose was therefore about 25 per cent. of what is recommended, and with such increments the optimal dose would rarely have been attained before the eight X ray treatments had terminated. Then again, immediate reaction, such as followed each time, would prevent the optimal dose of colloid being ascertained. The total dosage of colloid noted in the table is very low, less than one-third of what would be given here for these types and durations. As regards the colloid R.A.S. It is stated that the initial dose was 1 c.cm. and that it was increased by the same amount each week. In the article (Brit. Jour. Surg., 1934, xxi, 619) it is advised that the initial dose should be two-thirds of the last dose of S.Se. For example, a case of rectal carcinoma would probably end with 12 c.cm. of S.Se.; the initial dose of R.A.S. would be 8 c.cm., and in the three weeks after X radiation he would receive at least 24 c.cm. of R.A.S.—but at the Cancer Hospital he would only be given a total of 6 c.cm.

The X ray technique was standardised, each case received 75 r. It is advised that the X ray dosage should be altered to meet the findings in each case, and, at Bristol, doses from 30 to 150 r. are given. Patients only received eight séances, although it is advised that séances given before attaining the optimal dose of colloid should not be counted. This standardisation is possibly a corollary to immediate reaction or rigors, for neither optimal colloid nor X ray dosage could possibly be ascertained if rigors

occurred. Since X ray action is the product of séances and colloid dosage, the amount of ionisation per patient would not be more than about 20 per cent. of the optimal.

Much space is given to a case developing sulphæmoglobinæmia. No example of this has occurred amongst the hundreds treated at Bristol, but we guard very carefully against rigors and immediate reaction. It is possible that sulphæmoglobinæmia may follow faulty technique with some frequency.

The finding that the hæmatological reactions were not as are found here is not surprising; it is regarded as further evidence that the treatment given at the Cancer Hospital differed widely from that given at Bristol.

To sum up the more glaring of the errors: the dosages of colloid were far too low and chemical alteration occurred during injection; the X ray dosage was standardised, and, with the low dosage of colloid, must have been almost inoperative. Though these errors were pointed out, no effort was made to check them—from which one may make inferences better left unwritten. In spite of the fact that practically every error possible was stereotyped through the series, the results are not reported as being completely negative. It is therefore confidently concluded that no clinic need expect worse results than this report contains, and that genuine adherence to the published technique is likely to benefit the cancer patient to a degree comparable with that found here. Lastly, one is justified to ask why this burlesque was allowed to be published; a comparison of the method described with the original should have shown such discrepancies that to call it an independent test is far from the truth.

I am, Sir, yours faithfully,

Bristol, May 23rd.

A. T. TODD.

#### PROPHYLACTIC ENUCLEATION OF LOWER WISDOM TOOTH FOLLICLES

To the Editor of THE LANCET

SIR,—Mr. Bowdler Henry, in THE LANCET of April 18th, recommends the early removal of the germ of the lower third molar in cases where there is evidence that there will be a subsequent impaction, thereby avoiding all the dangers and difficulties which may follow the ordinary operation for the removal of the impacted tooth. The chief objection, however, to this operation is the difficulty of deciding whether a tooth germ will be subsequently impacted or not. It may appear to be irregularly placed at an early stage and yet erupt normally later. On the other hand, it may appear to be normal and fail to erupt when fully developed. It follows, therefore, that many of these operations may be performed on tooth germs which would erupt normally if allowed to develop or, alternatively, would develop in such a manner that their subsequent removal would be simple.

It would appear to be necessary, therefore, before accepting the prophylactic operation as a routine measure, to ascertain whether it is possible to diagnose with certainty a future impaction of the type which would necessitate a severe operation, and, if, so whether the tooth germs of probable impactions of this type are not themselves in such positions that their removal would present difficulties and dangers comparable with those encountered in the removal of impacted teeth. It must also be remembered that the great majority of impacted third molars can be removed with very little local or general disturbance, and that it is a question whether the fatalities and

difficulties which occur are not due to some idiosyncrasy of the patient or to local conditions which often occur in the third molar region when there is no impaction at all.

I am, Sir, yours faithfully,

Rickmansworth, May 15th.

S. WILSON CHARLES.

#### PORTRAITS OF PUBLIC HEALTH PIONEERS

To the Editor of THE LANCET

SIR,—In connexion with the public health section of our museum here, I am making a collection of the portraits of past pioneers in public health, and already have secured a considerable number. There are, however, several of whom so far I have been unable to trace portraits, and am venturing to append a list of these in the hope that some of your readers may be able to give me references to publications where any of these can be found, or in the event of their possessing portraits of any of them, would be willing to lend the same to me for copying.

Those particularly required are:

George Baker .. .. .	1722-1809
Sir Gilbert Blane .. .. .	1749-1834
Edwin Lankester .. .. .	1814-1874
John Haygarth (of Chester) .. .. .	1740-1827
Thomas Percival (of Manchester) .. .. .	1740-1804
C. Turner Thackrah (of Leeds) .. .. .	Died 1851

Any portraits entrusted to me would be carefully copied and returned with the least possible delay.

I am, Sir, yours faithfully,

H. B. NEWHAM,  
Director of the Museum.

London School of Hygiene and Tropical Medicine,  
Keppel-street, (Gower-street), W.C.1, May 22nd.

#### TUBERCULOUS CERVICAL GLANDS

To the Editor of THE LANCET

SIR,—I am interested to notice that Mr. Vernon Thompson has again raised the question of the propriety of operating in cases of tuberculous cervical glands. This matter has concerned me for many years and I have satisfied myself that there are circumstances in which an operation is the most important event in the treatment of some cases, whereas in others it is only a subsidiary and occasional requirement.

The whole question turns on the portal of entry in any individual case. When this route is the nasopharynx, then the tuberculosis of the corresponding cervical glands is probably a first and localised result of such infection and in these circumstances, the focus having been dealt with, the glands are best removed by radical operation. If, on the other hand, the glands in the neck are merely an outlying part of an infection which owes its origin to a portal in the mediastinum or mesentery, then the most important requirement is the efficient treatment of the individual to raise the resistance against the focus to the highest possible pitch. Even in the latter group, there may be glands that require excision because they break down or are the seat of repeated periadenitis, or are so obvious as to be an eyesore.

I have tried to set these matters out in some sort of order in various communications, especially in a paper in the *Newcastle Medical Journal* for July, 1931. I find that many members of the profession are still without an understanding of a pathological basis which might be a guide to successful treatment.

I am, Sir, yours faithfully,

G. GREY TURNER,  
Professor of Surgery, British Postgraduate  
Medical School.

May 20th.

**SYNTROPAN IN SEA-SICKNESS***To the Editor of THE LANCET*

SIR,—I have just returned from a ten weeks' voyage to South America as ship's surgeon and before leaving was induced by Prof. Stanton Hicks's letter, published in *THE LANCET* of Jan. 25th last, to take with me a supply of a new sea-sickness preparation produced by the Hoffmann-La Roche Chemical Works Ltd. The preparation is said to contain an antispasmodic of an atropine-like nature (Syntropan) and a mild sedative (Sedormid), but I may say that it was with a certain amount of scepticism that I used it, having heard of so many vaunted cures for this very distressing ailment.

Anyway I tried it out on about a dozen cases and in all with success. It had an immediate effect in all cases and those who were travelling under the best conditions reacted, as one would expect, most satisfactorily. Two of the crew who were sleeping right aft and above the propellers were the slowest in being cured, but the passengers only required a tablet or two and were then all right again and, moreover, had no recurrence although the sea was very rough at times. Feeling a little squeamish myself one day, I thought I would try it on myself. Although not really sick, I was not at all well, took one tablet, and in twenty minutes all feeling of discomfort had gone. I had no after-effects, no dryness of the mouth, no mydriasis, no palpitation.

All those to whom I gave the drug agreed that they felt immediate relief. I can cordially recommend it to other ship's surgeons who will gain great kudos from their seasick patients and win their gratitude for being relieved of what is a most distressing and discomforting ailment.

I am, Sir, yours faithfully,

THOS. NORTH, M.D., F.R.C.S.I.

Chiltern-court, N.W., May 25th.

**FAMILY MEDICAL INSURANCE***To the Editor of THE LANCET*

SIR,—I would like to make some observations on your very kind review of my book "Family Medical Insurance." Your reviewer states that the crucial chapter embodying the scheme whereby the "F.M.I." scheme is to be effected is "specific in certain immaterial details, but vague in what seem to be essentials for its comprehension." I admit the absence of financial or administrative details, but there are no statistical data available upon which to quote figures even provisionally for such services as proposed, while administrative details await investigation and coöperation of existing institutions and bodies. As is stated in the foreword, this is not a cut-and-dried scheme and those associated with me seek criticism and help. The main concern is that the problems raised shall not be shelved.

It is stated that the "F.M.I." scheme accentuates "the modern tendency to uncoördinated and disintegrated specialism." The whole object of the scheme is to improve the general practitioner service by a complete coördination and use of the specialities, with a consequent improvement, it is maintained, of the general practitioner's economic problems. This coördination is to be through existing institutions: the proposed clinics, wherever they be, are not mainly treatment centres but rather special investigation centres and "clearing houses." The report of the Scottish Consultative Council in Medical and Allied Services, which your reviewer quotes,

expresses as far as it is cited exactly the "F.M.I." principles.

The statement that periodical examinations, as proposed under the scheme, would result in the general practitioner becoming "a sort of middleman whose services are tolerated only because of their value in emergency" is hardly fair as it is definitely stated that the findings of such examinations "will be embodied in a report to the practitioner." They will not be given to the patient, and the doctor is of course free to adopt within reason what attitude he likes to the report.

While thanking you for your constructive criticism may I appeal for interest and support to enable us to carry out the spade work necessary for obtaining statistical and other data, and for the formation of a representative body to keep these problems before both the professional and lay citizen?

I am, Sir, yours faithfully,

Harley-street, W., May 25th.

J. LACHLAN-COPE.

**INDUCTION OF PREMATURE LABOUR***To the Editor of THE LANCET*

SIR,—In your leading article last week (p. 1191) you write: "It will be recalled that Mr. J. H. Peel recently published in our columns an account of a hundred consecutive cases in which induction had been performed for disproportion in primigravida." Reference to your columns (April 25th, 1936) shows that only *sixty* of the hundred cases were primigravida. The children of these primigravida induced by bougies had a stillbirth-rate of 20·8 per cent., a result due, I think, in part to the small number of cases and in part to the use of forceps to deliver (in no less than 35·8 per cent.). Of 85 primigravida induced at University College Hospital 10 children died (11·7 per cent.). Large statistics show that the maternal mortality-rate of induction in these cases is about 0·2 per cent., the infant mortality-rate about 12 per cent. What is wanted is not "negative evidence" but positive evidence, furnished by large statistics, showing that "trial labour" with its consequential forceps, Cæsarean section, or craniotomy can give equally good or better results.

I am, Sir, yours faithfully,

HERBERT R. SPENCER.

Bickenhall Mansions, W., May 23rd.

**OBSERVATIONS ON PEPTIC ULCER***To the Editor of THE LANCET*

SIR,—Dr. D. T. Davies's Bradshaw lecture, published in your issues of March 7th and 14th, contains statements and views which I cannot fully accept. May I offer the following comments?

Twenty years ago, at the 1st medical clinic of the University of Budapest, the healing without operation of a peptic ulcer of the lesser curvature, perforating between the layers of the lesser omentum, was observed. The size of the ulcer shadow greatly diminished after routine dietetic treatment,<sup>1</sup> and this accidental observation led us to the idea that callous and penetrating ulcers of the lesser curvature—which at that time were considered to be amenable only to surgical therapy—might possibly be cured in a simpler way, by instituting a careful dietetic regimen before perforation occurred. We found at that time 326 cases of peptic ulcer among 3500 patients coming to the clinic complaining of gastric discomfort, and in 35 cases of callous and penetrating ulcers of the lesser curvature we were able to follow systematically the course of the illness and the size of the ulcer.

<sup>1</sup> Rosenthal, E.: Berlin. klin. Woch., 1916, No. 34.

In all of these a progressive decrease in the size of the ulcer shadow or (in nearly all) complete disappearance of the ulcer niche was noted. When the late Prof. Bálint and I reported our experience before the Royal Hungarian Medical Association in 1917 I laid stress on the fact that callous ulcers of the lesser curvature can be cured by conservative regimen. This first observation of mine has since been corroborated, and here I need only mention that Schindler has been able to demonstrate by gastroscopic examination that disappearance of the ulcer shadow, as observed on the X ray screen, is tantamount to healing of the ulcer. Though I published my above-mentioned observations, together with some others concerning the treatment of peptic ulcer, somewhat later—in Hungarian in 1918, whereas my German monograph<sup>2</sup> appeared in Berlin in 1920—there can be no doubt that Davies is mistaken if, as appears from his lecture, he credits Nicholas and Moncrieff,<sup>3</sup> in 1927, with the first description of disappearance of the ulcer shadow after conservative treatment. Our observations on 35 cases were soon followed by accounts of 4 cases by Hamburger<sup>4</sup> of Chicago, and of 6 cases by Oehnell<sup>5</sup> of Stockholm. In my opinion the only reliable criterion of the healing of an ulcer is the disappearance of the ulcer shadow on X ray examination: this will explain my having gone at some length into its historical side.

I agree with Davies in attributing an important rôle to nervous impulses in the genesis and chronicity of peptic ulcers. I must add, however, that on the other hand favourable influences may considerably promote the healing of ulcers by way of the nervous system. This fact I emphasised in a post-graduate lecture given a few years ago. The chief source of unfavourable nervous influences is occupational worry and strain, and therefore I have always insisted on the importance of bed rest in ulcer treatment; hospital care is much to be preferred. In this way proper treatment of the ulcer may be better carried out, and, in addition, removal of the patient from his home is likely to be an advantage rather than not. Of course, there have been cases in which I have been obliged to adopt ambulatory treatment, because the patient could not afford to stay in bed for 4-6 weeks at home, or, still less, in hospital. With ambulatory treatment, however, symptoms will improve much more slowly and there is also considerable delay in disappearance of the ulcer shadow. Therefore I cannot endorse ambulatory treatment of ulcers as suggested by some authors and also by Davies.

Finally I wish to add some remarks on the acidity values as presented by Davies. In the monograph mentioned I pointed out that a true picture of acidity values associated with peptic ulcer can be obtained only if the data are arranged in separate groups according to the various locations of ulcers. Survey of unspecified data is not at all instructive; but if the percentage of hyperacid and non-hyperacid (normacid, hypacid, and anacid) ulcers on the lesser curvature, in the prepyloric region, at the pylorus, and in the duodenum is examined, interesting data will be obtained. Thus duodenal and pyloric ulcers are often associated with hyperacidity (70 and 55 per cent. respectively), whereas with ulcers of the prepyloric region and of the lesser curvature increased

secretion is much less common (28 and 30 per cent. respectively). It will be observed, first, that the proportion of hyperacid cases varies with the site of the ulcer, a marked increase being observed towards the duodenum; and secondly—and not less important—that in a considerable number of ulcers there is normal, decreased, or deficient secretion of acid. These facts have caused me to abandon the inviting and almost traditional theory of ætiological relationship between hyperacidity and peptic ulcer. Cholelithiasis, too, is often associated with excessive acid values; but the coincidence of peptic ulcer and cholelithiasis is rare.

For the time being the problem of the causation of peptic ulcer is not completely understood. The importance of changes in the internal milieu, emphasised by Bálint and possibly supported by recent observations of Dodds, cannot be evaluated until further proof is available. Meanwhile, in order to promote unprejudiced development of our views, it seems best to consider that a strict ætiological relationship between hyperacidity and peptic ulcer has not been definitely established.

I am, Sir, yours faithfully,

Budapest, May 6th.

EUGENE ROSENTHAL.

### PUERPERAL SCARLET FEVER

To the Editor of THE LANCET

SIR,—The article by Drs. Burton and Weir in your issue of May 16th on the inter-relationships of streptococcal disease, and your leading article in the same issue, have led me to recall an experience of my own fifty years or more ago. The relations of scarlet fever and puerperal fever were then being hotly debated in the medical papers; some of the best known obstetricians in London took part in this discussion and, as was to be expected in such a difficult question, expressed widely different opinions.

At that time I was (unqualified) assistant in a practice in an agricultural district which consisted of five separate villages distant from each other about three miles. In the month of February I saw in one of these villages a severe case of scarlet fever; the medical officer of health failed to trace its origin, and there had been no case in the district for months. Within a week I took scarlet fever (I had attended scores of cases before) and the next day the young son of my principal was taken ill with a temperature of 105.2° F. followed by convulsions and died next day. He had no rash. My attack was mild, my rash was of the slightest, and I kept bed for only one day, and in two days more I went my rounds quite well without faucial or nasal discharge. Within a week I was sent at night to a case of confinement in an isolated village. The case was easy and normal and nothing was done to the patient. The following day (32 hours after confinement) the patient was very well, but the day after the husband came in haste on horseback to fetch me, when I found the woman with a temperature of 105.2° F., sore-throat, very dry strawberry tongue, and delirium. She died the next day. Two days afterwards three children in the same house came out with mild scarlet fever. The outbreak did not spread further.

This was perhaps the most tragic event in my long professional life, and it so impressed me that I have hardly referred to it since, except as a warning to my assistants. The causal connexion between scarlet fever and puerperal fever was indelibly imprinted on my mind.

I am, Sir, yours faithfully,

Ystalyfera, Swansea, May 20th.

## TEST-MEALS IN THE DIAGNOSIS OF GASTRIC CANCER

To the Editor of THE LANCET

SIR,—Two articles in your issues of May 16th and 23rd reveal a striking difference of opinion about the value of test-meals in the diagnosis of gastric cancer. Sir James Walton (p. 1101) apparently regards test-meals as valuable aids to diagnosis. Prof. Anschütz (p. 1175) does not even mention them, but relies on a combination of radiology and the occult blood test. While no one would deny the importance of the latter, it does seem strange that one should expect to learn more about the stomach from the stools than from the gastric contents.

Having recently made a statistical inquiry into this very subject (THE LANCET, 1934, ii., 471), may I suggest that the test-meal is of value in diagnosing gastric cancer, particularly in those cases exhibiting achlorhydria with a doubtful radiological picture. The point as I see it is briefly this: Achlorhydria by itself means little, for it will be found in from 10 to 25 per cent. of normal persons in the cancer age-period, but *achlorhydria plus gastric deformity of any type* is extremely suggestive of carcinoma. This is because only about 2 per cent. of benign ulcers have achlorhydria—even less if histamine is used—while the incidence of achlorhydria in carcinoma of the stomach is about 70 per cent. The well-known changes in the resting juice must also be mentioned, although they are perhaps rarely an early manifestation of malignant disease.

I feel that these considerations indicate sufficiently

the diagnostic value of the test-meal in all cases where the stomach is abnormal radiologically. Even a "simple" gastric ulcer crater should be viewed with suspicion if associated with achlorhydria.

I am, Sir, yours faithfully,

N. F. MACLAGAN.

Westminster Hospital, S.W., May 26th.

## THE BIOCHEMICAL LESION

To the Editor of THE LANCET

SIR,—The lecture by Prof. Peters in your last issue is important to students of nervous pathology. He shows very clearly that serious organic changes will result from a biochemical lesion; that, to quote his words, "the absence of an important factor in the development of energy from carbohydrates would be sufficient to stop the normal functioning of some groups of nerve-cells. Those which normally had most work to do might be expected to run out of their supply of the catalyst B<sub>1</sub> sooner than others." Replace this catalyst by some enzyme necessary to normal tissue oxidations, and of which there is a certain deficiency in an individual, and the result will be such changes as are met with in the psychoses, especially if any extra strain is thrown on certain cell groups from which the greatest energy is required. In the treatment of such conditions what the nerve-cell needs above all is rest and freedom from fussy interference.

I am, Sir, yours faithfully,

B. H. SHAW,

Medical Superintendent, Staffordshire  
Mental Hospital.

May 25th.

## PANEL AND CONTRACT PRACTICE

### Public Medical Services

THE Essex public medical service, which was founded in 1923 to provide medical attendance on the families of insured persons on a contract basis, has issued its twelfth report. At the end of 1935, after deducting cancellations, there were 16,534 books on which payments were being made, an increase of 1668 over the previous year. These books represent 15,231 adults and 13,725 children, treatment for whom is provided by 263 active and 82 honorary members. The largest totals collected for individual practices were: metropolitan £364, urban £1250, semi-rural £377, and rural £510. The appliances fund gave help in 62 cases, 35 of which were surgical belts, trusses, &c., and the remainder elastic stockings and bandages, special drugs, ambulance charges, doctors' bills, nursing, and massage. On the year's working there is a balance of income over expenditure of £540. Collections totalled £21,207, some £2000 in excess of the previous year, payments to doctors were £16,075, and a sum of £5126 was transferred to office account. The collections would have shown an even better figure but for bad weather and illness among the collectors at the end of December.

A similar service in and around Brighton covers Hove, Portslade, and now Southwick. Its personnel is increasing—88 doctors as compared with 77 at the commencement of the year and 108 pharmacists as against 96. During the year 6489 persons joined the scheme, and accessions average a hundred a week. The participants are of all ages from a

few weeks old upwards; medical services have been provided under the scheme for 1015 children under ten years of age.

### Benefit Overpayments

The insurance doctor is often the detached friend to whom his insured patients bring their troubles for solution. The alleged non-payment, or underpayment, of sickness benefit is one of the commonest of these troubles and one of its causes may be overlooked by the practitioner when trying to suggest what has gone wrong. One does not often get too much change at a booking office, but it seems that too much sickness benefit is occasionally paid out, and the society concerned then has to do its best to get repayment from the insured person. Clearly it is better if possible to secure this, if necessary in instalments, while the member is well and earning wages, but, if he refuses, other means have to be adopted. The overpayment is a debt due from the member to the society which is entitled to take reasonable steps to recover. But the extent to which a society is entitled as of right to secure the repayment of benefit previously overpaid by withholding benefits which become due later is limited:

- (1) to a period within four years of the date on which the overpayment was made;
- (2) the deduction must not exceed one-fourth of the amount which would otherwise be payable; it may be claimed
- (3) from sickness or disablement benefit only, not from maternity benefit.

In certain cases the right to recover is not restricted

as above—e.g., when excess benefit has been paid in the following circumstances :

(a) an advance pending settlement of a compensation claim ;

(b) an advance to a disabled ex-Service man pending settlement of a claim to a maximum rate disability pension ;

(c) benefit overpaid to a married woman owing to her failure to notify the society of her marriage.

In the event of the insured person concerned in (a)

being a woman deduction may be made from maternity benefit payable from her own insurance, and the same applies to (c). The benefit rates for married women who continue to be employed are now different from those applying to their unmarried sisters. An overpayment made to a husband cannot however be deducted from maternity benefit payable from his insurance in respect of his wife's confinement ; for this benefit is the property of the wife.

## PUBLIC HEALTH

### London Maternity Services

IN a report to the hospitals and medical services committee of the L.C.C. just issued (London : P. S. King and Son. No. 3195. 1s.) Sir Frederick Menzies has much of interest to say about the 65,300 confinements which occurred in London in 1934. Rather more than a fifth of these women (13,250) were confined in L.C.C. hospitals, and of these 87 per cent. had received antenatal care at L.C.C. clinics and most of the remainder some supervision by doctors, midwives, or borough clinics. Practically all the 32,000 women attended by voluntary associations had received antenatal care as a condition of attendance. Ample opportunities for regular supervision are available in London through the borough clinics if not through the attendant with whom the woman books for her confinement, and this opportunity is evidently appreciated. The women attend as often as is asked and travel long distances if required. Lapsed cases are very few, and if a woman fails to receive antenatal care in London it is either (a) because she belongs to a small and recalcitrant class who think it is not worth while ; (b) because she is a multipara who is bound by household ties and has lost her fear of childbirth ; or (c) because she is a single girl deterred for obvious social reasons. Judged by the conditions considered adequate at L.C.C. clinics, the antenatal care provided by experienced midwives may seem inadequate, but it stands the test of success. It seems that certain institutions, such as the East End Maternity Hospital, which claim a low mortality-rate, particularly from toxæmia, had this low rate before routine antenatal care began.

There was little to criticise during the year in the conduct before admission of cases which died in L.C.C. hospitals. Five years ago, it is said, there were twelve deaths where grave criticism could be made of the persons responsible for the treatment provided before admission ; in 1934 there were only four such cases. An examination of the notes of the 458 women delivered in hospital who subsequently died and of a large number of others delivered before admission does not show a single case of gross error on the part of a midwife. In fact during the past three years no midwife has been referred by the L.C.C. to the C.M.B. on account of neglect or malpractice.

Lack of reasonable facilities is held to play little part in contributing to the maternal mortality-rate in London. The L.C.C. hospitals are open to all and refuse no patient either for antenatal care, confinement, abortion, or abnormal puerperium. It is the policy of the L.C.C. to make a maternity unit sufficiently large to have a highly skilled resident staff on duty for 24 hours of the 365 days in the year. Certain of the boroughs provide excellent domiciliary services for which there seems to be a diminishing demand. Moreover an ample supply of competent private midwives is available but, it is added, in

many cases under present conditions they cannot make an adequate living. The lack of facilities, says Sir Frederick, which seems of most practical importance in London as elsewhere, is that midwives are obliged to send for doctors, suggested by their patients, who may have no special experience in midwifery.

According to this report the preventability of maternal death and the allocation of its blame are by no means so certain and absolute as has been supposed. Insufficient attention has been paid to the fact that the deaths analysed came from districts with widely differing mortality-rates. The maternal mortality-rate, like all other rates in public health, will inevitably be much easier to reduce if above the average than if below the average. Of every two deaths in childbirth one has been regarded as avoidable ; it is, Sir Frederick thinks, perhaps nearer the truth to regard 6 to 8 out of 10 deaths in some areas as avoidable, in other areas only one or two.

An interesting paragraph suggests reasons for the fact that the maternal mortality-rate for the East End of London is and always has been lower than for the West End, especially as regards sepsis. This may be explained partly by the higher proportion of primiparæ and of illegitimate births in the western boroughs, partly by the much higher proportion of confinements in hospital in the eastern boroughs.

### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 16TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week : Small-pox, 1 (Hove) ; scarlet fever, 2000 ; diphtheria, 904 ; enteric fever, 24 ; pneumonia (primary or influenza), 887 ; puerperal fever, 48 ; puerperal pyrexia, 121 ; cerebro-spinal fever, 19 ; acute poliomyelitis, 3 ; encephalitis lethargica, 4 ; dysentery, 12 ; ophthalmia neonatorum, 114. No case of cholera, plague, or typhus fever was notified during the week.

The case of small-pox notified from Hove was included among the four cases in East Sussex on which comment was made last week (p. 1209).

The number of cases in the Infectious Hospitals of the London County Council on May 22nd was 5626, which included : Scarlet fever, 1026 ; diphtheria, 814 ; measles, 2561 ; whooping-cough, 563 ; puerperal fever, 21 mothers (plus 14 babies) ; encephalitis lethargica, 284 ; poliomyelitis, 2. At St. Margaret's Hospital there were 22 babies (plus 12 mothers) with ophthalmia neonatorum.

*Deaths.*—In 122 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 61 (31) from measles, 8 (3) from scarlet fever, 23 (3) from whooping-cough, 28 (4) from diphtheria, 55 (16) from diarrhoea and enteritis under two years, and 42 (10) from influenza. The figures in parentheses are those for London itself.

Leeds reported 4 deaths from measles, Liverpool, Bristol, Gloucester, and Great Yarmouth each 2. Deaths from diphtheria were reported from 20 great towns, 3 from Manchester, no more than 2 from any other large town. Gateshead had 3 deaths from whooping-cough. The only fatal case of typhoid was at Lincoln.

The number of stillbirths notified during the week was 286 (corresponding to a rate of 40 per 1000 total births), including 45 in London.

## GENERAL MEDICAL COUNCIL

## PRESIDENT'S ADDRESS

IN opening the 143rd session on Tuesday last Sir Norman Walker began by speaking of the loss sustained by the Council through the death of Prof. Francis Dixon and Sir John Marnoch. The former had represented the University of Dublin since 1916 "and as the years went on became probably the best beloved of our members." His successor, Prof. J. W. Bigger, was the third son to follow a father on the Council (the others being Mr. Pridgin Teale and Sir Humphry Rolleston). Besides Dr. Bigger, the new representatives whom the President welcomed were Prof. David Campbell (Aberdeen University) and Prof. E. W. Hey Groves (Royal College of Surgeons of England).

After paying tribute to the work of the late Mr. Farquhar Macrae, inspector of examinations, and latterly as secretary of the new Medical Council of India, Sir Norman mentioned that Sir Robert Bolam's appointment at Durham brought the number of vice-chancellors at present on the Council to four, and then turned to the statistics of the profession.

"The number of medical students registered in England in 1935," he said, "was the second highest on record, 1363, 12 less than that of the peak year of 1919, and 269 more than last year. Scotland had five fewer at 719, and Ireland 11 fewer at 521. 1884 names were added to the Medical Register by registration in 1935. Deducting deaths and removals for other reasons, the net addition is 1057, 27 more than the average of the last 20 years, raising the total number of registered practitioners to 58,363, 867 more than last year."

The Medical Council of India, Sir Norman Walker continued, had applied for the recognition of the degrees of certain Indian universities. Up to 1920 the executive committee had accepted for registration the degrees and diplomas of the universities of Bombay, Calcutta, Lucknow (Allahabad), Madras, and the Punjab. In 1921, however, a questionnaire on the teaching of midwifery was addressed to these universities and the replies showed that this was not, save in Madras, of a standard which would be recognised for licensing bodies in this country. With

the object of finding a solution of an admittedly difficult question Sir Norman had accepted an invitation to proceed to India and to discuss the difficulties with the authorities there. In his report to the Secretary of State in 1922 he considered it possible for each of the universities to arrange that its regulations could be brought sufficiently into accordance with the resolutions and recommendations of the Council to enable the Council to continue to recognise its diplomas. He proposed that the services of Colonel R. A. Needham, deputy director-general of the Indian Medical Service, who accompanied him throughout his tour, should be accepted as those of inspector, and for four or five years Colonel Needham's careful and conscientious reports were the basis of the Council's continued recognition of the degrees. In 1926 Sir Norman again went to India to report on the progress that had been made, not only in the teaching of midwifery, but in regard to the subjects of medicine and surgery also, and found evidence of general improvement almost everywhere. In September, 1933, an Act was passed constituting a Medical Council of India, with a constitution on lines similar to that of the General Medical Council, and Mr. Farquhar Macrae became its first secretary.

"Now for the future: there are eight universities under the jurisdiction of the Medical Council of India which confer degrees—Andhra, Bombay, Calcutta, Lucknow, Madras, Patna, Punjab, and Rangoon. The reports of medical inspectors to the Indian Council on Bombay, Lucknow, and Patna were received just before the meeting of the executive committee in February, and that on Madras in March. These have been carefully considered by the executive committee, and they resolved yesterday that the degrees of M.B., B.S. granted by the universities of Bombay, Lucknow, and Madras (together with other qualifications granted by the universities of Bombay and Madras which were previously registrable) should again be recognised for registration if granted on or after Feb. 25th, 1930; and that the degrees of M.B., B.S. granted by the University of Patna should be recognised for registration if granted on or after May 11th, 1935."

The President announced that Wednesday and Thursday mornings would be devoted to discussion of the medical curriculum. The Council then proceeded to a consideration of penal cases.

## PARLIAMENTARY INTELLIGENCE

## MIDWIVES BILL IN COMMITTEE

ON May 21st and 26th the Midwives Bill was further considered by Standing Committee C. of the House of Commons.

## Midwives' Salaries

Discussion continued on the amendment moved by Mr. E. DUNN providing that the salary of midwives employed under the Bill should in no case be less than that of health visitors employed by the authority, or working in the same area.

Mr. G. GRIFFITHS said that the Minister of Health should not leave it to voluntary organisations to fix the salary of midwives. Such a course would be very dangerous. The Minister through the local authorities should decide that the minimum salary for midwives should be at least equal to that of the health visitors.

Mr. LYONS appealed to the Minister to give an assurance that in the circular which he proposed to send to local authorities on this subject he would lay down a satisfactory minimum salary for midwives so as to ensure the best working of the system.

Mr. LEACH said that the Minister had made it clear that he proposed to put in his circular to local authorities the statement that in his judgment the status of midwives should be regarded as akin to that of health visitors. If that were the case he might just as well put it in the Bill by accepting the amendment. Over and over again in that committee reference had been made to the low pay of midwives, but no figures had yet been produced. Dr. Moore had told a conference in 1929 that the average income of midwives practising in Huddersfield, 39 in all, was £58 2s. 6d.; he was satisfied that the figure had not risen since. The Maternal Mortality Committee had said that good midwifery could never be self-supporting in working-class areas.

Sir KINGSLEY WOOD said that the difference between himself and those who supported this amendment was the difference between democracy and autocracy. Midwives were as much the servants of local authorities as health visitors, and if they were to maintain proper democratic government in this country they must trust local authorities to fix the remuneration of their own servants. Broadly

speaking the local authorities had fixed the salaries of health visitors at a satisfactory figure—there might be some exceptions—and he trusted they would do the same for midwives. If in any case it was found that midwives were not properly paid the Minister had the final power in his hand of withholding the Government grant.

The amendment was negated by 23 votes to 15.

Mr. SILVERMAN moved an amendment providing that the proposals to be submitted to the Minister by local authorities should include the provision by the authority of sterilised maternity outfits in every case.—Sir KINGSLEY WOOD said that the local authorities already had power to provide such outfits.—The amendment was negated.

#### L.C.C. and Borough Councils

Mr. KEELING moved an amendment providing that the L.C.C. should not employ midwives in the area of any metropolitan borough council unless the L.C.C. satisfied the Minister that it was impracticable to make efficient arrangements with such borough council either directly or through a voluntary organisation. The committee had rejected an amendment on behalf of the non-county provincial boroughs, but the case of the London boroughs for running midwifery services of their own was far stronger. A great part of the Minister's argument against the provincial boroughs was that they were so small. Could the Minister justify the anomaly whereby Wimbledon with a population of 60,000 was to have its own midwives, whereas the adjoining metropolitan borough of Wandsworth with a population of 360,000 was to be handed over to the L.C.C.? Many of the London boroughs went far beyond the requirements of the Bill in providing gynaecologists and bacteriological services and there was proof of their efficiency in the fact that in both 1934 and 1935 the maternal mortality of London was little more than half what it was in the provinces. The L.C.C. had no experience of domiciliary work; it only dealt with cases in hospitals and other institutions. The borough councils were in a position to make arrangements with both the voluntary and municipal hospitals.

Sir KINGSLEY WOOD said he was afraid that if the amendment were carried it would make the difficulties of administration almost worse than if the borough councils were entrusted with all the duties under the Bill. The special position of London arose from the very large number of voluntary hospitals which had external midwifery services in the metropolitan area. In London there were 22 voluntary hospitals with external midwifery services and two of those hospitals actually served parts of seven boroughs and five others served parts of six boroughs. If the amendment were carried the L.C.C. would presumably have to make all the arrangements with the voluntary hospitals in London so far as the external midwifery work was concerned, and then the appointment of midwives was apparently to shift over to the borough councils. That would be a hopeless and impossible position.

Major HILLS said that the metropolitan boroughs had built up health services which were a model to the world. He pleaded for a unified service for the whole of health provided that the authority was large enough to give a substantial choice of midwives to the mother and had shown that it had the capacity to run a health service efficiently. He wanted to see more care given before and after the birth of the child. He could not see how the midwifery services in these boroughs were going to be made better by the L.C.C.

The amendment was negated by 32 votes to 5.

#### Financial Provision

Mr. LEACH moved an amendment providing that a midwife employed by an authority in pursuance of this Act should be entitled to travelling expenses incurred in the discharge of her duties in accordance with the scale approved by the authority.—Mr. SHAKESPEARE said that every local authority naturally provided travelling

expenses for all its servants and midwives would be included. He could give the hon. Member an assurance on that point.—Sir J. HASLAM said that he remembered the day when doctors generally went to their cases on bicycles. Now they nearly all had motor-cars and the result was that they arrived fresh and fit for their work. He thought it was desirable that midwives should also be encouraged to be fresh when they arrived at their cases.—The amendment was by leave withdrawn.

Mr. SHAKESPEARE secured agreement on an amendment giving power to the Minister to see that justice was done to old and infirm midwives by local authorities in respect of compensation for their practices.

Mr. FRANKEL raised the question of the grants to local authorities for midwifery services, and suggested that under the provisions of the Bill many authorities would be forced to go slow in the development of the work.—Mr. SHAKESPEARE said he thought that Mr. Frankel was unreasonably apprehensive. Local authorities were as keen as any member of the Government to see these services operating. When the Ministry of Health were negotiating with the local authorities the suggestion was made that they should block grant this service straight away, but the local authorities pointed out that they wanted a number of years to find out exactly what the service would cost before the service was stabilised in a block grant. Therefore it was arranged that for the third grant period—from April 1st, 1937, to March 31st, 1942—the grant should be an annual grant related to the new expenditure for each of the five years. He thought that the great bulk or all of the local authorities would be able within five years to get an efficient midwifery service running.

### HOUSE OF COMMONS

WEDNESDAY, MAY 20TH

#### Pit Refuse and Public Health

Mr. KENNEDY asked the Secretary of State for Scotland if he was aware of the complaints regarding the deposit of refuse from the Lochhead Pit, Fifeshire, into a passing stream causing what was regarded as a menace to public health in the neighbourhood of East Wemyss; and if steps could be taken to abate the nuisance.—Colonel COLVILLE, Under-Secretary of State for Scotland, replied: I am informed that no refuse is deposited in the Den Burn from Lochhead Pit but that pit water is discharged into the burn. The county medical officer of health is satisfied that no danger to health is involved, and as water in the condition in which it is raised from the mine is exempt from the operation of the Rivers Pollution Prevention Acts my right hon. friend is unable to intervene. I am informed that flooding from the stream has recently occurred at East Wemyss and this matter is at present under the local authority's consideration.

#### Female Labour in Mines

Mr. HEPWORTH asked the Minister of Labour which countries had not ratified the covenant adopted by the International Labour Conference, 1935, prohibiting the employment of female manual workers on underground work in mines; and whether any such work was permitted in any part of the British Empire.—Lieut.-Colonel MUIRHEAD, Parliamentary Secretary to the Ministry of Labour, replied: So far as I am aware, no country except Cuba has yet ratified the draft convention prohibiting the employment of women on underground work in mines of all kinds, but I would point out that the period allowed by the Treaty of Peace within which States must bring draft conventions before the competent authority for legislation or other action has not yet expired. The intention of H.M. Government to ratify this convention was notified to Parliament in a Command Paper (No. 5141) laid last March. With regard to the second part of the question, the employment of women underground in mines is prohibited in the United Kingdom. I am advised that in the large majority of the non-self-governing Colonial dependencies where mines exist such employment is prohibited by law, and that in the very few territories where no legislation to this effect has been enacted women are not so employed.

THURSDAY, MAY 21ST

**Inflammable Toys**

Mr. LEACH asked the Home Secretary if he was yet in a position to introduce legislation for the prevention of injury and death due to the numerous everyday articles, particularly toys, on sale made of celluloid or other highly inflammable substance, which were purchased mostly by a public ignorant of the danger incurred.—Sir JOHN SIMON replied: I am afraid that this is a matter which it would be most difficult to deal with by legislation.

**Vocational Training of Deaf Boys and Girls**

Sir WILLIAM JENKINS asked the President of the Board of Education if he would take steps to educate and train deaf boys and girls to some suitable vocation and make it compulsory upon education authorities to equip all adults in some industry.—Mr. OLIVER STANLEY replied: Vocational training is given in special schools for the deaf to children under 16, and five vocational courses for deaf students over 16 are recognised by the Board. I am not at present satisfied that a sufficient case exists for making it compulsory for local education authorities to provide such training for deaf adults.

**Public Assistance to Persons Over Sixty-Five**

Mr. HERBERT WILLIAMS asked the Minister of Health what proportion of the persons, other than dependants, in receipt of poor relief were over the age of 65.—Sir KINGSLEY WOOD replied: On Jan. 1st, 1936, the proportion of the total number of men and women in receipt of poor relief (excluding rate-aided patients in mental hospitals) who were over 65 years of age was 31 per cent. The figure for men and women, excluding dependent wives, is not available, but the corresponding proportion for men only was 34 per cent.

**Housing of Aged Persons**

Miss WARD asked the Minister of Health whether local authorities would qualify for subsidy under the Overcrowding Act by erecting special houses for old people and using the houses vacated by these persons for housing people for whom accommodation had to be provided as a result of the provisions of the Overcrowding Act.—Sir KINGSLEY WOOD replied: Exchequer subsidy would be available for houses built in the circumstances indicated by my hon. friend, if the conditions of the Act are otherwise satisfied. I referred to the desirability of building special houses for old people in a circular which I issued in October last.

MONDAY, MAY 25TH

**The Case of Mr. Bunner**

Mr. COCKS asked the Secretary of State for Foreign Affairs whether he could give the House any further information regarding the case of Mr. Bunner, the British subject who was arrested by the Italians at Dire Dawa.—Mr. EDEN replied: As my noble friend informed the House on Thursday last, as soon as press reports of Mr. Bunner's arrest reached London, a telegram was sent to His Majesty's Minister at Addis Ababa asking him to ascertain the facts. When on Saturday definite information reached me that Mr. Bunner was under arrest, H.M. Ambassador at Rome lost no time in taking up this case, on instructions from H.M. Government, with the Italian Government. I am happy to be able to state that I have now received a telegram from H.M. Consul at Harar stating that Mr. Bunner has now been freed, and that he was due to leave for the coast on the evening of May 23rd. I will circulate a detailed account of this case.

The following is the statement referred to: A telegram was sent by H.M. Consul at Harar to H.M. Minister at Addis Ababa on May 22nd and received in London from Sir Sidney Barton on May 24th. In this telegram H.M. Consul stated that Mr. Bunner was now free and was due to leave with the rest of the British ambulance by the next train, on May 23rd evening or Sunday morning. An order had been made for the value of the money seized to be returned to him in lira. Meanwhile, through the kind assistance of the French Consulate and the French doctors Renault and Martin, Mr. Bunner had started a series of antirabies injections with good serum, and

Dr. Empey, the head of the British ambulance, was being given a sufficient quantity of serum to complete the course. The sequence of events appeared to have been as follows: Mr. Bunner had been denounced by one, Gabre Christos, who was said to be of Turkish birth but Ethiopian by naturalisation, as Captain Rudolph Brunner, an Austrian formerly employed with the Ethiopian military forces in the Ogaden. This charge was supported by an Ethiopian boy, aged about 12, formerly a body servant to Vehip Pasha. In view of the above evidence, the Italian authorities interrogated Mr. Bunner during the evening of May 17th, and wishing to continue interrogation the following day, kept him in custody that night in a room which he described as an incinerator. Hearing that he might be shot before the Italian authorities discovered their mistake, he escaped during the night. This seemed to the Italian authorities to confirm his guilt. He was re-arrested on the evening of May 20th. When H.M. Consul saw him on the 21st he looked none the worse for his adventure. H.M. Consul secured his immediate release on his personal parole that he would produce him when required. He then joined the rest of the Ambulance, which had decided to remain until the affair was settled. This satisfactory outcome, which had been achieved by vigorous representations to the Italian authorities, was confirmed by telegram to Dire Dawas from General Fuizzi, commanding in Harar. Difficulties were accentuated by Mr. Bunner's ignorance of any language but English, the absence of his passport which had gone on to Jibuti, the military character of his rank and of the wording of the instructions found on him from his superiors in the Ambulance, and finally his attempted escape. Undoubtedly Mr. Bunner should not have been held under close arrest on the night of the 17th after H.M. Consul had once stood sponsor for him. But I understand that this was an act of inferior officials misled by statements of lying witnesses and by the production of the visiting card of Rudolph Brunner inscribed as Captain of the Ethiopian Army which Gabre Christos alleged Mr. Bunner had given him.

**Service Recruits and Physical Unfitness**

Mr. KENNEDY asked the Prime Minister the number of applicants for enlistment in the Army, Navy, and Air Force in England, Scotland, and Wales, respectively, who had been rejected on the ground of physical unfitness during the last 12 months; and how many of the intending recruits were unemployed at the date of their application for enlistment.—Mr. BALDWIN replied: The number of applicants from April 1st, 1935, to March 31st, 1936, who have been rejected on the grounds of physical unfitness are:—

			Army.		Navy.
England	..	..	18,765	....	18,212
Scotland	..	..	3,654	....	2,709
Wales ..	..	..	1,442	....	1,095
			23,861		22,016

Similar figures for the Royal Air Force are not available for the three countries separately, but the total number of such rejections was 8558, of whom 526 were examined in Belfast. As regards the last part of the question, I regret that the information is not available.

**Town and Country Planning**

Lieut.-Colonel MOORE asked the Minister of Health in what approximate percentage of cases in the last 12 months where an appeal was made to him under the Town and Country Planning Act, 1932, and the Town and Country Planning (General Interim Development) Order, 1933, a decision was given favourable to the local authority.—Sir KINGSLEY WOOD replied: The approximate percentage of interim development appeals dealt with during the 12 months ended April 30th, 1936, on which a decision was given favourable to the local authority was 34. In 49 per cent. agreement was reached between the parties or the appeals otherwise lapsed. In the remaining 17 per cent. the appeals were allowed.

**Small-pox**

Mr. LEACH asked the Minister of Health how many cases of small-pox had been discovered by the port

authorities of London, Liverpool, Bristol, and Cardiff on ships arriving at those ports during the last 20 years.—Sir KINGSLEY WOOD replied: The following are the Notifications of Small-pox in Port Sanitary Districts for the years 1916–35 inclusive:—

London .. ..	39	Bristol .. ..	2
Liverpool .. ..	30	Cardiff .. ..	4

TUESDAY, MAY 26TH

### Maternal Mortality in Scotland

Mr. MATHERS asked the Secretary of State for Scotland if he was now in a position to make a statement with regard to legislation to deal with the problem of maternal mortality in Scotland.—Sir GODFREY COLLINS replied: I hope that it will be possible during the present session to secure the passage into law of a Scottish Bill dealing with this subject.

### Influenza and the Common Cold

Mr. LEES-JONES asked the Secretary of State for War what experiments and/or investigations had been made on behalf of the War Office into the prevention and cure of the common cold and influenza within the last six years; and what success, if any, had attended them.—Mr. DUFF COOPER replied: Investigations have been undertaken in vaccine therapy and in prevention by extensive hygienic precautions, without, however, satisfactory evidence being obtained as to the efficacy of vaccines in relation to either influenza or the common cold. An inquiry now being conducted in collaboration with the Medical Research Council, however, gives hope of more promising results.

### Royal Army Medical Corps Deficiency

Mr. DAY asked the Secretary of State for War the deficiency in the authorised establishment of the Royal Army Medical Corps; and whether he could give the reason for this shortage.—Mr. DUFF COOPER replied: The deficiency is 60 officers and 309 other ranks. As regards officers, the shortage, which is being temporarily met by the employment of 38 temporary commissioned officers and a number of civilian medical practitioners, is a considerable improvement on the deficiency of 97 which existed when the present conditions of service came into operation two years ago, and I have every reason to hope that it will be made good at no distant date. The reason for the shortage must, of course, be a matter of opinion, but in the case of other ranks, it is accentuated by a recent increase of 169 in the establishment.

### Sale of "Prepared" Honey

Mr. PERKINS asked the Minister of Health whether he was aware that a commodity composed of a mixture of sugar and other ingredients, including a small proportion of honey, was being sold as honey; and whether he would take steps to protect the public from this deception.—Mr. SHAKESPEARE replied: My right hon. friend is aware that a substance which is not pure honey is sold under the name of "prepared honey" with a label indicating that it is a mixture. My right hon. friend has no power to take any action in the matter, but if the circumstances of the sale are such as to constitute an offence under the Food and Drugs (Adulteration) Act, the duty of enforcement rests on the local authorities, and it is also open to any person to take proceedings.

## MEDICAL NEWS

### University of Oxford

Dr. H. A. B. Whitlocke and Dr. A. S. MacNalty have been nominated for election to the board of the faculty of medicine in place of Dr. C. F. T. East and Dr. C. P. Symonds who are retiring.

### University of London

Mr. Arthur Wormald, D.Sc., senior lecturer in biochemistry in the University of Leeds, has been appointed to the university chair of biochemistry tenable at St. Bartholomew's Hospital medical college, and Dr. W. F. Harper, lecturer in anatomy in the University of Aberdeen, to the university readership in anatomy tenable at London Hospital medical college.

Dr. Wormald was born in 1900 and educated at Leeds Modern School and the University of Leeds, where he graduated B.Sc. in 1921, his studies being interrupted by seven months' war service in 1918. He went on to take his M.Sc. in 1924 and his D.Sc. in 1930, while acting as demonstrator in biochemistry at the University. In 1926 he was appointed to a lectureship and in 1933 became senior lecturer. In June, 1928, he was granted a year's leave of absence, while holding a Rockefeller medical fellowship, to study the chemistry of immunology at the Rockefeller Institute for Medical Research, New York. In 1930 he was sent out to Uganda by the Colonial Office and carried out biochemical and immunological studies on sleeping-sickness. Dr. Wormald has contributed many articles to biochemical and bacteriological journals.

Dr. Harper, who is 35 years of age, was educated at St. Andrews, where he studied first in the faculty of science, obtaining his B.Sc. degree with first-class honours in 1923. After three years spent in research as holder of a grant from the Department of Scientific and Industrial Research and as a Carnegie scholar, he took his Ph.D. degree. In 1930 he graduated as M.B. St. And., with honours, and was awarded the Rutherford gold medal. In the same year he was appointed assistant in the department of anatomy, and in 1931 lecturer in regional anatomy at University College, Dundee. After taking his M.D. with honours he moved in 1934 to Aberdeen to take up his present post. Among other subjects he has written on the vascularity of human cardiac valves and on Dupuytren's contraction in the thumb.

### University of Leeds

Dr. Albert Hemingway has been appointed to the chair of physiology and Mr. L. R. Braithwaite to the chair of surgery.

Dr. Hemingway graduated B.Sc. with first-class honours in physiology at the University of Leeds in 1922, and took his M.B. in 1925. He has held the posts of demonstrator in the department of physiology at King's College, and senior assistant at University College, London. In 1927 he was appointed to his present post of lecturer in experimental physiology at the

Welsh National School of Medicine, Cardiff. His published work is largely concerned with the kidney.

Mr. Braithwaite, who is at present clinical lecturer in surgery in the University, is a graduate of medicine of both Leeds and Manchester, and became a fellow of the Royal College of Surgeons of England in 1907. After qualification he held house appointments at the Leeds General Infirmary, to which he is now honorary surgeon. During the war he held a major's commission in the Royal Army Medical Corps. In 1923 he was Arris and Gale lecturer at the Royal College of Surgeons, and in 1933 he was elected a member of the council. He is the author of many papers on surgical subjects, especially on the pathology and surgery of the abdomen.

### Society of Apothecaries of London

At recent examinations the following candidates were successful:—

*Surgery.*—H. O. Dole, Univ. of Manch.; R. C. H. Ensor, Queens Univ., Belf., and Guy's Hosp.; C. J. Roberts, Westminster Hosp.; and J. K. Sargentson, Univ. of Camb. and St. Mary's Hosp.

*Medicine.*—H. Bentovim, Univ. of Manch.; N. Bickford, Univ. of Camb. and Middlesex Hosp.; and M. Q. H. Siddiki, Univ. of Leeds.

*Forensic Medicine.*—H. Bentovim, Univ. of Manch.; and M. Q. H. Siddiki, Univ. of Leeds.

*Midwifery.*—F. C. E. Diamond, Univ. of Durh.; L. W. La Chard, St. George's Hosp.; M. V. Matthew, Univ. of Manch.; and J. S. Wood, Univ. of Liverp.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: H. Bentovim, H. O. Dole, R. C. H. Ensor, and M. Q. H. Siddiki.

### A Scholarship in Sociology

The council of Bedford College for Women will award next month on the recommendation of the Lady Huggins committee a scholarship of the value of £70 for one year for study or research in some branch of sociology. The scholarship is open to women holding a university degree, preference being given to graduates who have taken honours in philosophy, psychology, economics, or sociology. It would give opportunity for a recently qualified medical woman to spend a year studying some subject common to medicine and social science, such as hospital administration or health on a new housing estate. The successful candidate will be expected to enter upon her work in October, 1936. Applications must reach the principal of Bedford College, Regent's Park, London, N.W.1, by June 6th.

### National University of Ireland

At a meeting of the senate on May 21st it was decided that the hon. degree of D.Sc. should be conferred upon Dr. Simon Flexner, director of the Rockefeller Institute for Medical Research since its foundation.

### Manchester Medical Society

At the annual meeting of this society on May 6th, Mr. Garnett Wright was elected president for the coming year. Dr. L. A. Parry gave an address summarised on p. 1276.

### Research Scholarship in Tropical Medicine

The London School of Hygiene and Tropical Medicine invites applications for the Wandsworth scholarship which will be vacant from Oct. 1st. The scholar, who need not hold a medical qualification, will be required to devote his whole time to research in tropical medicine. Further information will be found in our advertisements columns.

### A Tribute to Dr. Morax

On May 15th, at the end of the annual congress of the Société Française d'Ophthalmologie, a portrait of the late Dr. Victor Morax was unveiled at the Lariboisière Hospital. Speeches were made in his honour by Dr. Magitot, Dr. Coutela, Dr. Coppez, and others. Mr. A. F. MacCallan represented the Ophthalmological Society of the United Kingdom.

### Medical Congress in Brussels

The Journées Médicales de Bruxelles will be held this year from June 20th to 24th under the presidency of Prof. Robert Danis. The opening address will be given by Dr. Maurice Bedel who will present a "petition to doctors in the name of the sick." The secretary of the congress is Dr. R. Beckers, 141, rue Belliard, Brussels.

### Research Defence Society

The annual general meeting of this society will be held at the London School of Hygiene, Keppel-street, W.C., on Tuesday, June 9th, at 3 p.m., when Sir Malcolm Watson will deliver the tenth Stephen Paget memorial lecture. His lecture will be entitled Manson, Ross, and Reed, Pioneers in Research on Tropical Diseases.

### Royal Infirmary, Edinburgh

Last week Lady Kinnaird, wife of the Lord High Commissioner, laid the foundation-stone of the new nurses' home at this hospital. The building is to be one of seven floors of fireproof construction. There are to be six stairways and four lifts, and gardens will be built on the roof. It will contain 278 bedrooms, each fitted with a wash-hand basin and built-in furniture. There will be one bath available for every five nurses, while shampoo rooms and pantries are to be arranged on each floor. A ward for sick nurses will accommodate 22 patients. The ground floor of the building is to be allocated entirely to recreation and sitting-rooms which, if necessary, can be converted into one room of 140 ft. in length for special functions.

### International Organisation against Trachoma

A meeting was held in Paris on May 11th during the annual congress of the French Ophthalmological Society, when an introductory address was given by the president of the organisation, Mr. A. F. MacCallan, and papers on the treatment of trachoma in children were read by him, Dr. Wibaut (Holland), and Dr. Zachert (Poland). In the discussion which followed Dr. Ragazzi and Prof. Baslini (Italy), Dr. Joseph Jitta (League of Nations), Dr. Aubaret (France), Dr. Nataf (Tunisia), and Dr. Marin Amat (Spain) took part. Later on the same day there was a combined meeting of this organisation with the International Association for the Prevention of Blindness under the presidency of Prof. de Lapersonne, when Prof. Terrien read a paper on the classification of conjunctivitis, Dr. R. P. Wilson gave an account of conjunctivitis in Egypt, and Mr. MacCallan reported on the relationship between conjunctivitis and trachoma. The reports of Dr. Park Lewis (U.S.A.) and of Mr. Bishop Harman (London) were circulated. Copies of proceedings may be had from the International Association at 66, Boulevard Saint-Michel, Paris, 6e.

The Spanish Government has conferred the decoration of Comendador de la Orden de la República upon Sir Henry Wellcome, F.R.S., founder of the Wellcome Research Institution, London.

### University College Hospital

The King has consented to become the patron of this hospital, which since its foundation in 1833 has always been under the patronage of the reigning sovereign.

### Liverpool School of Tropical Medicine

A four days' course of instruction in hygiene for non-medical people proceeding to the tropics will be held at the school from Tuesday, June 9th, to Friday, the 12th. Further particulars may be had from the laboratory secretary at the school.

### Institute of Medical Psychology

An intensive short course, open only to registered medical practitioners, will be held in the evenings and on Saturday afternoons from June 15th to 27th at this institute. The lecturers will be Dr. Emanuel Miller, Dr. J. A. Hadfield, Dr. H. Crichton-Miller, Dr. H. V. Dicks, Dr. Laura Hutton, and Dr. William Nunan. The course is intended for those with some knowledge of elementary principles. Further information may be had from the educational secretary at the institute, Malet-place, W.C.1.

### Royal Edinburgh Hospital for Sick Children

The annual report of this hospital shows that its work is still increasing. During 1935 3144 cases were treated in the wards and there were nearly 28,000 attendances at the out-patient department. There was also a considerable increase in the work carried out in the urological, radiological, massage, and sunlight departments. The ordinary expenditure for the year was £19,437, which was less than the ordinary income by £4590. Legacies and donations received during the year amounted to over £21,000.

### Hospital Study Tour in Czechoslovakia

A tour has been organised by the International Hospital Association and the Association of Czechoslovakian Hospitals, from August 29th to Sept 15th, for those connected with hospital work and organisation. Among the towns to be visited are Carlsbad, Prague, Zlin, Brunn, and Moravská Ostrava. Visits will be paid to the Government Health Institute in Prague, the Masaryk Home in Kre, the Bata Hospital and Social Welfare Institution in Zlin, the tuberculosis department of the Municipal Hospital at Bulovka, and the sanatoriums of the high Tatra mountains. Further particulars may be obtained from the Czechoslovak Travel Bureau (Cedok), Ltd., 21, Regent-street, London, S.W.1.

### Canadian Rheumatic Disease Association

An association with this name has been formed to study and control rheumatic diseases in Canada. It is a branch of the Ligue Internationale contre le Rheumatisme, and will cooperate with the Canadian Medical Association. At the inaugural meeting Dr. J. C. Meakins (Montreal) was elected hon. president, Dr. Almon A. Fletcher (Toronto) president, and Dr. W. S. Barnhart (Ottawa) secretary.

### Testimonial to Dr. R. D. Clarkson

On May 22nd Dr. R. D. Clarkson, who has retired from the office of medical superintendent of the Royal Scottish National Institution, Larbert, was entertained to dinner in the Caledonian Hotel, Edinburgh. The Earl of Marr and Kellie, in proposing Dr. Clarkson's health, spoke of his record of strenuous, anxious, and successful work over 41 years. Dr. Clarkson, in replying, referred to the change since 1894 when interest in mental deficiency was confined to a very small number of religious and philanthropic people. Prof. D. K. Henderson said that the Institution had great traditions and had created confidence. It had become something bigger than an institution: it was a community with an organised society of doctors, nurses, teachers, and tradespeople all doing what they possibly could for the welfare of those in their charge.

A presentation was made to Dr. and Mrs. Clarkson in recognition of their service.

### Australian and New Zealand Association for the Advancement of Science

A meeting of this association is to be held in Auckland, New Zealand, from Jan. 12th to 19th, 1937. Medical men who are likely to attend this meeting, and who wish to present papers to the section of medical science and national health, are asked to communicate with the sectional secretary, Dr. J. Egerton Caughey, 3, Alfred-street, Auckland, N.Z., at their earliest convenience.

### Brazilian Society of Orthopædic Surgery

The first of the annual congresses that the new Sociedade Brasileira de Orthopedia e Traumatologia intends to promote will be held in Sao Paulo, Brazil, at the beginning of June. Prof. Rezende Puech will preside, and Prof. Vittorio Putti will attend at the special invitation of the society. Subsequent congresses will take place in the different capitals of the Brazilian States.

### Demonstrations of Contraceptive Technique

On Thursday, June 4th, at 2.30 p.m., at the clinic (106, Whitfield-street, W.) a practical demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs. Marie Stopes, D.Sc., and Dr. Evelyn Fisher. Application for tickets from medical practitioners and senior students should be made to the hon. secretary at the clinic.

### Excursions to Russia

Dr. Stella Churchill is forming a party to visit Russia, leaving London on June 27th. The journey will be made by sea between London Bridge and Leningrad and arrangements will be made to visit in that city and in Moscow special centres of social and medical interest. In Leningrad the party will have an opportunity of inspecting the Pavlov, Yaffa, and Semenov Institutes, the Metchnikov Hospital, radiological and optical institutes, and creches with their playgrounds. In Moscow attention is drawn to the visits to be made to the abortion and birth control clinic, the institutes of nutrition, tropical research, and, especially, of genetics. Houses of correction, rest homes, and workers' clubs will also be open for inspection. The inclusive price to tourists of all necessary requirements from London back to London is set down at £36, though optional extensions at approximately £1 15s. per day can be arranged if notice is given before departure. Further particulars can be obtained from the Wayfarers Travel Agency Ltd., 33, Gordon-square, London, W.C.1.

A letter on p. 1261 announces arrangements made through the Society for Cultural Relations with Soviet Russia, 3, Bedford-place, London, W.C.1, for a study by medical men of Russian health services. The S.C.R. party starts a week earlier, but for most of the time the visits will be simultaneous.

### Association of Industrial Medical Officers

The fourth meeting of this association was held in Birmingham at the end of last week. After the business meeting on May 22nd a paper on Labour Management and Medical Service, read by Dr. H. B. Trumper, a regional medical officer, I.C.I., was discussed by Prof. M. Culpin and Mr. R. Lloyd Roberts, chief labour officer, I.C.I., present as a guest. The importance of the industrial medical officer being in close contact with works management was emphasised. In the evening the association was entertained to dinner in the Midland Hotel by the directors of Imperial Chemical Industries Ltd., with Mr. J. Rogers in the chair. Amongst the guests were Dr. Stanley Barnes (dean of the Faculty of Medicine), Dr. M. W. Paterson, (hon. sec. of the Association of Certifying Factory Surgeons), Dr. E. R. A. Merewether (H.M. Medical Inspector of Factories), and Dr. Clyde McKenzie. The toast of "The Association" given by the chairman was replied to by Dr. N. Howard Mummery (J. Lyons and Co.) and Dr. L. P. Lockhart (Boots Pure Drug Co.). On May 23rd at I.C.I. Metals Limited, Witton, a discussion on the Treatment of Industrial Injuries was opened by Dr. Donald Stewart (I.C.I.) and Dr. Margaret Hossell (Rowntree's). Members of the association had the opportunity of seeing in detail much of the non-ferrous metal industry, the potential risks of injury, and the measures taken to safeguard health and welfare.

### Royal Society of Tropical Medicine and Hygiene

The King has consented to become a patron of this society.

### Orthopædic Clinics in Cornwall

The work of orthopædic clinics in this county is greatly on the increase. Six years ago only 90 cases were under treatment during a year; in 1935 the total was 1148, and 32 beds instead of 14 are to be reserved for this work at the Royal Cornwall Infirmary.

### Society for Relief of Widows and Orphans of Medical Men

The annual general meeting of this society was held in London on May 20th with the president, Mr. V. Warren Low, in the chair. During the past year £4914 was distributed in grants to the widows and orphans of members. The grant to widows over sixty-five years of age was £75 each; to those under sixty-five £65, and to orphans £50 each. In addition a Christmas present of £15 was made to each widow over seventy-five, £10 to each widow under that age, and £10 to each orphan. On the last day of 1935 there were 51 widows and 8 orphans in receipt of grants, which by the constitution of the society are made only to the necessitous widows and orphans of deceased members. Special grants are made to orphans over the age of sixteen, at which age the ordinary grants cease, to enable them to study for some business or professional career. In 1935 a sum of £194 was distributed with this object. During the year 6 widows in receipt of grants had died; 1 of these had been on the funds for 15 years and received in grants £1210. Her husband on election had paid a life-subscription of £21. The total membership of the society is now 263. Membership is open to any registered medical practitioner who, at the time of his election, is resident within a 20-mile radius of Charing Cross. Admitted under thirty-five years of age the annual subscription is two guineas. Full particulars from the secretary of the society at 11, Chandos-street, London, W.1.

## Births, Marriages, and Deaths

### BIRTHS

- BASSETT.—On May 21st, the wife of John Mories Bassett, M.D., F.R.C.S. Edin., of Cranley-gardens, London, S.W., of a son.
- CLEGG.—On May 24th, the wife of Hugh Clegg, M.R.C.P., of 27, Lawn-road, N.W.3, of a son.
- DAVISON.—On May 16th, to Grace Davison, M.B. Durh., the wife of Max Davison, M.B. Durh., of Dorking—a daughter.
- FOSSEL.—On May 22nd, to Attie (née Joekes), wife of Dr. Max Fossel, of Graz, Austria—a son.
- LEASK.—On May 14th, at Southampton, the wife of Dr. Norman H. Leask, of Southampton, of a son.
- MOODY.—On May 12th, at Ilford, the wife of Dr. J. Arthur Moody, of a son.
- SIMS.—On May 17th, at Exeter, the wife of Dr. Charles Sims, of a daughter.
- THOMSON.—On May 21st, the wife of Dr. Robert Thomson, of New Cavendish-street, W., of a son.

### MARRIAGES

- DAWE—TURNER.—On May 14th, at St. Andrew's Church, Bath, J. H. Dawe, M.B. Edin., of Bath, to Rosanna, youngest daughter of the late Edward Turner of Greenwich.
- SHUTTLEWORTH—CUSHING.—On May 9th, at Southwark Cathedral, Cyril William Thomas Shuttleworth, M.R.C.S., L.D.S., of New Eltham, to Yvonne Alicia Cushing, only daughter of Dr. and Mrs. Cushing of Bristol.

### DEATHS

- CAMPBELL.—On May 24th, at Walton-on-the-Hill, Tadworth, Surrey, Surgeon Lieut.-Col. William Campbell, late Grenadier Guards, aged 86.
- DIGBY.—On May 19th, at Felixstowe, William Everard Sherrard Digby, M.R.C.S. Eng., late West African Medical Service, and of Rushmere, Ipswich.
- HEWETSON.—On May 19th, at Birmingham, John Thomas Hewetson, M.D., F.R.C.S., in his 64th year.
- HUGHES.—On May 23rd, at Cookshill, Mundesley, Norfolk, Lieut.-Col. Thomas Arthur Hughes, M.D., Sc.D. Dub., F.R.C.P. Lond., I.M.S., aged 51.
- JEANS.—On May 25th, at a London nursing-home, Alfred Norman George Jeans, M.R.C.S. Eng., of Holmfild-court, Belsize-grove, N.W., son of the late Sir Alexander Jeans of Liverpool.
- MASON.—On May 17th, at 216, Braid-road, Edinburgh, Victor Harold Mason, M.C., M.B., Ch.B.
- WORTHINGTON.—On May 17th, at Birchington, Kent, Harry Edward Worthington, M.R.C.S. Eng., aged 69.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Appointments

BECCLE, L. F., M.B. Lond., has been appointed Coroner for Romford.  
 WALDRON, F. R., M.D. N.U.I., D.P.H., Medical Officer of Health for Greenwich.  
 WALKER, D. G., M.B., B.Dent.Sc., Hon. Assistant Dental Surgeon to the Royal Dental Hospital of London.  
 Certifying Surgeons under the Factory and Workshop Acts: Dr. J. D. CRERAR (Tutbury District, Staffs); Dr. H. D. LANDER (Burnham-on-Crouch District, Essex, formerly known as Southminster); Dr. G. R. BURNETT (Keswick District, Cumberland); and Dr. R. A. NEILL (Middlewich District, Cheshire).

## Vacancies

For further information refer to the advertisement columns

**Albert Dock Hospital, Connaught-road, E.**—Res. M.O. At rate of £110.  
**Ashton-under-Lyne District Infirmary.**—Res. Surg. O. and H.S. At rate of £200 and £150 respectively.  
**Aylesbury, Royal Buckinghamshire Hospital.**—Sen. Res. M.O. At rate of £200.  
**Barnsley, Beckett Hospital and Dispensary.**—H.P. £200.  
**Bath, Royal United Hospital.**—Hon. Asst. Gynecologist and Obstetrician.  
**Battersea General Hospital, S.W.**—H.P. and Cas. O. At rate of £120.  
**Boole General Hospital.**—H.S. or Cas. O. At rate of £150.  
**Bradford Royal Infirmary.**—H.P. At rate of £135.  
**Brighton, Borough Infectious Disease Hospital and Sanatorium.**—Sen. Res. M.O. £400.  
**Brighton, New Sussex Hospital for Women, Windlesham-road.**—H.S. £100.  
**Bristol, Brentry Colony for Male Mental Defectives, Westbury-on-Trym.**—Res. Med. Supt. £800.  
**Bristol Eye Hospital.**—Jun. H.S. At rate of £100.  
**Bristol Royal Infirmary.**—Medical and Surgical Registrars. Each £400. Also Sen. Res. M.O. £200.  
**Bristol, Southmead Municipal General Hospital.**—Jun. Asst. Res. M.O. At rate of £200.  
**British Postgraduate Medical School, Duane-road, W.**—First Asst. to Obstet. and Gyn. Dept. £300.  
**Burnley, Municipal General Hospital.**—Jun. Res. M.O. £150.  
**Cambridge, Addenbrooke's Hospital.**—Res. Anaesthetist and Emergency Officer. At rate of £130.  
**Cardiff, University College of South Wales and Monmouthshire.**—Lecturer in Experimental Physiology. £750.  
**City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.**—Surg. and Med. Regs. £225 and £175 respectively. Also H.P. At rate of £100. Also Asst. Radiologist.  
**City of London Maternity Hospital, City-road, E.C.**—Jun. Res. M.O. At rate of £80.  
**Connaught Hospital, Walthamstow, E.**—Dental Clin. Assts. 1 guinea per session.  
**Coventry and Warwickshire Hospital.**—Res. H.P. £160.  
**Derby, Derbyshire Royal Infirmary.**—H.S. £150.  
**Dreadnought Hospital, Greenwich, S.E.**—H.P. and H.S. Each at rate of £110.  
**Dunedin, N.Z., Otago Hospital.**—Radiotherapist. £800.  
**East Ham Memorial Hospital, Shrewsbury-road, E.**—H.S. to Spec. Depts. and Cas. O. At rate of £120. Also Hon. Ophth. Surgeon.  
**Eastern Dispensary, Leman-street, E.**—Physician.  
**Great Yarmouth General Hospital.**—H.S. £140.  
**Hammersmith Hospital, Duane-road, W.**—Asst. Radiologist. £700.  
**Hartlepool Hospital.**—Second H.S. At rate of £150.  
**Holt, Norfolk, Kelling Sanatorium.**—Second Asst. Res. M.O. £350.  
**Hospital for Sick Children, Great Ormond-street, W.C.**—Ophth. Surgeon. Also Res. Aural Reg. £150.  
**Hospital for Tropical Diseases, Gordon-street, W.C.**—H.P. At rate of £120.  
**Hull, Municipal Maternity Home and Infants' Hospital, Hedon-road.**—Sen. Res. M.O. £450.  
**Hull Royal Infirmary.**—H.S. to Ophth. and Ear, Nose, and Throat Dept. At rate of £150. Also H.S. to Sutton Branch Hospital. At rate of £160.  
**Ilford, King George Hospital.**—Res. Cas. O. and Surg. Reg., Res. Med. Reg. Each £150. Two Res. H.S.'s. Each £100. Also Hon. Asst. Dermatologist.  
**Ipswich, East Suffolk and Ipswich Hospital.**—H.S. £144.  
**Kettering and District General Hospital.**—Second Res. M.O. At rate of £125.  
**Kidderminster and District General Hospital.**—H.S. £150.  
**Leek, Cheddleton Mental Hospital.**—Asst. M.O. £600.  
**Leicester City Mental Hospital, Humberstone.**—Sen. Asst. M.O. £700. Also Third Asst. Res. M.O. £350.  
**Leyton Borough.**—Deputy M.O.H. and Deputy School M.O. £660.  
**Liverpool Port Sanitary Authority.**—Asst. Port M.O. £700.  
**Liverpool Royal Babies' Hospital.**—Res. M.O. At rate of £90.  
**Liverpool Sanatorium, Delamere Forest, Frodsham.**—Second Asst. to Med. Supt. £250.  
**Liverpool Stanley Hospital.**—H.S. At rate of £100.  
**Liverpool University.**—Supervisor of Dental Mechanics and Dental Prosthetics. £750.  
**Liverpool, Walton Hospital.**—Second Sen. Res. Obstet. and Gyn. Officer. £350.  
**Llanelli and District General and Eye Hospital.**—Res. Med. Supt. £300.

**London County Council.**—M.O. (Grade I.). £350. Asst. M.O.'s (Grade II.). Each £250. Also Temp. Dist. M.O. At rate of £235.  
**London Homoeopathic Hospital, Great Ormond-street, W.C.**—H.S. At rate of £100.  
**London School of Hygiene and Tropical Medicine, Keppel-street, W.C.**—Wandsworth Scholarship. £350.  
**Maidstone, West Kent General Hospital.**—H.S. £175.  
**Manchester, Ancoats Hospital.**—Combined H.S. (Aural) and H.P. post. At rate of £100.  
**Manchester, Christie Hospital and Holt Radium Institute, Withington.**—Res. Surg. O. At rate of £150.  
**Manchester, Crumpsall Hospital and Institution.**—Jun. Asst. M.O. At rate of £200.  
**Manchester, St. Mary's Hospitals.**—Four H.S.'s for Special Depts. Each at rate of £50.  
**Middlesbrough, North Riding Infirmary.**—Third H.S. At rate of £125.  
**Mildmay Mission Hospital, Austin-street, E.**—Asst. Cas. O. At rate of £125.  
**Monmouthshire County Council.**—Asst. M.O. £500.  
**National Hospital for Diseases of the Nervous System, Queen-square, W.C.**—Asst. Registrar. £200.  
**National Temperance Hospital, Hampstead-road, N.W.**—Res. M.O. At rate of £175. Also Cas. O. and H.S. At rate of £120 and £100 respectively.  
**Norwich, Norfolk Mental Hospital.**—Asst. M.O. £350.  
**Nottingham General Hospital.**—H.S. At rate of £150.  
**Oldham County Borough.**—Asst. M.O.H. and Asst. Tuberc. Officer. £750.  
**Oldham Royal Infirmary.**—H.S. At rate of £175.  
**Preston and County of Lancaster Royal Infirmary.**—Cas. H.S. £150.  
**Princess Elizabeth of York Hospital for Children, Shadwell, E.**—Cas. O., H.P., and H.S. Each at rate of £125.  
**Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.**—H.S. At rate of £100.  
**Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.**—Res. Anaesthetist. At rate of £100. Res. Anaesthetist and Dist. Res. M.O. At rate of £90. Also Asst. Res. M.O. At rate of £80.  
**Queen Mary's Hospital for the East End, E.**—Res. M.O. and two Cas. and Out-patients' Officers. Each at rate of £150. H.S.'s, H.P., Obstet. H.S., and Res. Anaesthetist and H.P. Each at rate of £120. Also Hon. Asst. Surgeon.  
**Queen's Hospital for Children, Hackney-road, E.**—Psychiatrist, Radium Beam Therapy Research, &c., 16, Riding House-street, W.—Asst. M.O. At rate of £250.  
**Reading, Royal Berkshire Hospital.**—Hon. Asst. Anaesthetist, Retford, Notts, Rampton State Institution for Mental Defectives.—Medical Officer. £515.  
**Rotherham County Borough.**—Asst. M.O. £300.  
**Royal Chest Hospital, City-road, E.C.**—Surgeon.  
**Royal Free Hospital, Gray's Inn-road, W.C.**—Res. Cas. O. and Res. Anaesthetist. At rate of £150 and £75 respectively. Also Children's Third H.S.  
**Royal Northern Hospital, Holloway, N.**—Hon. Radiologist.  
**St. Bartholomew's Hospital, E.C.**—Asst. Physician to Children's Dept. Also Asst. Surgeon.  
**St. John's Hospital, Lewisham, S.E.**—H.S. At rate of £100.  
**St. Mark's Hospital for Cancer, &c., City-road, E.C.**—H.S. At rate of £65.  
**St. Peter's Hospital for Stone, &c., Henrietta-street, W.C.**—Clin. Assts. to Hon. Staff.  
**Salford Royal Hospital.**—Res. Surg. O. £200. Also two H.S.'s. Each at rate of £125.  
**Salvation Army Mothers' Hospital, Lower Clapton-road, E.**—Hon. Obstet. Surgeon. Also Hon. Clin. Asst.  
**Shrewsbury, Royal Salop Infirmary.**—Res. Surg. O. £250.  
**Souhampton, Isolation Hospital and Sanatorium.**—Jun. Res. M.O. £200.  
**Southampton, Royal South Hants and Southampton Hospital.**—H.S. to Ear, Nose, and Throat Dept., and Res. Anaesthetist. At rate of £150.  
**South Eastern Hospital for Children, Sydenham, S.E.**—Jun. Res. M.O. At rate of £100.  
**Southend-on-Sea General Hospital.**—Med. Reg. and R.M.O. £300.  
**Southport General Infirmary.**—Sen. and Jun. H.S.'s. £200 and £150 respectively.  
**Taunton and Somerset Hospital.**—H.P. At rate of £100.  
**Truro, Royal Cornwall Infirmary.**—Hon. Surgeon.  
**University of London, King's College, Strand, W.C.**—Asst. Lecturer and Research Worker. £300.  
**Wadley Mental Hospital, near Sheffield.**—Sen. Asst. M.O. £650.  
**Wakefield Mental Hospital.**—Asst. M.O. £350.  
**West Ham County Borough.**—Asst. School M.O. £500.  
**West London Hospital, Hammersmith-road, W.**—Res. Asst. Surgeon. £200. Med. Reg. to Children's Dept. £100. Also two H.S.'s, H.P., and Res. Cas. O. Each at rate of £100.  
**Westminster Hospital, Broad Sanctuary, S.W.**—Two Radiologists.  
**Wolverhampton Royal Hospital.**—H.P. and H.S. At rate of £125 and £100 respectively.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Duns (Berwick), Presteign (Radnor), and Enfield (Middlesex).

**LEWES VICTORIA HOSPITAL.**—The nurses' home at this hospital, which has been erected at a cost of £4500, will shortly be ready for occupation. Six beds are to be added to each of the hospital's wards, and it is intended to provide more beds for paying patients. To complete this extension scheme a further sum of £3000 is needed.

## NOTES, COMMENTS, AND ABSTRACTS

## SOME PSYCHOLOGICAL FACTORS IN SICKNESS ABSENTEEISM \*

BY THOMAS M. LING, B.M. Oxon., M.R.C.P. Lond.  
MEDICAL OFFICER, JOSEPH LUCAS LTD., BIRMINGHAM

DURING the year 1934 the insured population of this country, approximately 14 million in number, lost roughly 28 million weeks in sickness, or an average of 14 days per person. Between 45 per cent. and 50 per cent. of these people were ill at one time or another during the year, and in some districts the proportion rises to 70 per cent. This loss falls in ever-widening circles on the individuals themselves, their families, society, and the industrial structure. During the same period the loss of time due to industrial disputes was only 10 per cent. of that due to sickness. The economic and moral loss eventuating to the nation from disputes is recognised by all thinking people, and the marked decline in these figures during the last decade may be regarded as a striking justification for the conciliatory steps that have been taken by all those concerned. If the far greater problem of sickness absenteeism is faced during the coming years with the same objective realism, there is no reason why results as valuable should not be obtained, but from the very nature of the problem, it is one where medicine must cooperate with the allied fields of sociology, economics, and psychology in a common effort. Quite apart from the urgency and perhaps the intangibility of the subject, the most striking feature is the reorientation demanded in our own viewpoints as practitioners of medicine. It is notorious that every age is one of change and it would seem that these changes are taking place around us at an ever-increasing speed. Modern industry, rationalisation, the aggregation of a large number of people earning their livings as members of a single unit, all bring in their trail new problems, with which we, as doctors, are intimately concerned. The relationship of people to their work, to the organisation by which they are employed, and to their associates in the organisation, whether above or below them, all play a highly significant part in the individual's mental contentment and his capacity to deal with "the slings and arrows of outrageous fortune," whether these be physical illness, domestic troubles, or the just reprimands of his superiors.

The great developments of public health have solved many of the pressing problems of physical disease that bore so heavily on the employed classes during the last century; typhoid fever, scurvy, and alcoholic cirrhosis are to-day clinical curiosities, thanks largely to improved education and the excellence of our various health services; tuberculosis has shown a most striking decline, due probably to improved nutrition and the various preventive measures that have been taken since Osler spoke of it so feelingly at the beginning of the century. Despite these improvements, for which our profession and the various lay organisations concerned can feel justifiable satisfaction, the sickness rates among the insured population are disquietingly high and the subject is now a major social problem pressing for solution.

Just as clinical diseases change, so must our viewpoint change to face the new situation that has arisen and evidence is rapidly accumulating to show that psychological factors are playing an increasingly prominent part and that no consideration of the subject is complete without an appreciation of the importance of this aspect.

## The Old and the New Viewpoint

The emphasis placed on morbid anatomy and detectable structural changes during the last 50 years

\* Paper read before the Association of Industrial Medical Officers at the London School of Hygiene and Tropical Medicine on March 27th, 1936.

has overshadowed the aggravating emotional disharmonies that always coexist in cases of frank "organic" illness and that in many cases may so alter visceral functioning that the patient is partly or completely incapacitated from taking his place in a gregarious community. This emphasis on terminal changes and the attempt to deduce from them a clear picture of the living patient has resulted in what may be termed a "nosographical" method of diagnosis. The objective in such an approach is to place the patient in one or another medical pigeon-hole. It consists, in other words, in the determination of a nosographical label, a label of one of the "diseases" to be applied to the patient; for example, duodenal ulcer or mitral stenosis or migraine. But the emphasis so placed on the organic and bacteriological method of diagnosis, which is still the predominant method utilised in contemporary medicine, has caused a serious misconception regarding disease and the methods to be used for its alleviation, especially among ambulatory patients. Those who see and appreciate only organic diseases, as a natural sequence, have divided individuals who seek advice for their health into those who are really ill—that is who show predominant morbid manifestations in an organ, or give evidence of a distinct infection with a particular micro-organism, and those who are not really ill—that is those in whom no organic manifestation and no infection can be found. These last individuals are classified as "functional" or "neurotic" and are in general dismissed either with smiling encouragement and the questionable piece of advice that there is really nothing the matter with them, or with an atmosphere of frank disapproval or contempt for not "pulling themselves together." Such an attitude is really indefensible from all points of view: a patient who feels ill is ill and is as worthy of all the help that we can give him, as the individual with the rare but dramatic disease manifesting itself as a tumour or an unusual association of cranial nerve palsies. To divide individuals into "organic" and "functional" must result in a form of therapeutic nihilism and it is only by considering and treating primarily the person's "dis-ease" and not the "disease" that we shall obtain the binocular vision required to see man as a whole.

It is perhaps insufficiently recognised that definite physical conditions can be brought about by a mental cause, although we all recognise that an emotion can make one feel very happy or make one depressed according to its implications. A persistent emotional disharmony can in addition cause headache, indigestion, and generalised autonomic spasm with all its attendant sequelae. Thus Cannon,<sup>1</sup> in speaking of emotions and bodily changes, tells a story of a woman patient who had to come up to a city from the country to have a test-meal done, and after spending the night at her hotel went along in the early morning to the pathologist. The meal was withdrawn, but with it was returned the majority of her previous evening's dinner, quite undigested. The explanation for this was that the lady's husband, having come up to town with her, had unfortunately gone out on an alcoholic party that night. The test was repeated the following morning under happier domestic circumstances and the results were perfectly normal. This is a well-marked example of a morbid process that is found in many people, and that plays an unexpectedly important part in this whole question of sickness absenteeism and its relation to the vegetative neuroses.

It is admittedly very difficult to modify our earlier teaching, which has stressed the fact that morbid anatomical changes must always precede changes of function, while in reality the reaction is a reversible one. Actually the deciding factor adopted by the disciple of the "mechanistic" or Virchow School for deciding whether the individual is suffering from

an "organic" or "functional" condition, is the instrument he happens to use to record the abnormality of the organ under observation. Just at present the instrument on which most reliance is placed is the microscope with a limit of magnification of about twelve hundred diameters. Suppose that to-morrow some physicist invents a microscope with a much greater magnification. At once abnormalities may be seen where none was visible previously. But why confine ourselves to the microscope? Certainly there are other ways of recording abnormalities of the human organism besides visual observation of fixed and sectioned tissues. For example, the spectroscopist may show us that a certain type of sugar is found in the urine of an athlete before a race. This is an observation which may be recorded photographically; it is a phenomenon which can be shown to occur regularly; by chemical methods the sugar may be estimated quantitatively. The average histopathologist, nevertheless, will maintain strenuously that there is no organic pathology in this anxious runner and that the disease is merely functional. What the pathologist really means is that after an autopsy on this athlete no lesion would be visible in stained sections of tissue with a microscope of the type in use in 1936. The impossibility of drawing a line between "organic" and "functional" is succinctly expressed by the German physician, Dr. Mohr<sup>2</sup> :—

"There is no such thing as a purely psychic illness or a purely physical one, but only a *living event* taking place in a living organism, which is itself alive only by virtue of the fact that in it psychic and somatic are united in an indissoluble unity."

#### Extent of the Psychoneuroses

This modern or Neo-Hippocratic approach has its immediate application to the problem of sickness absenteeism and its causative factors, as evidenced in the various reports published during the last few years by the Industrial Health Research Board. The attendant problems referred to in these publications throw into relief the complexity of the subject. What is a "normal" sickness rate? When does a person cease to be sick and become disabled? To what extent do local economic and sociological factors influence the situation? To all these questions, and to many more, the answers are as yet not clear; *inter alia* the policy of individual firms to their sick employees obviously plays a big part. If a company readily dismisses its sick workers, it will have an apparently low rate that will not be statistically comparable with those of a firm with a more developed social viewpoint. Despite all these variables, the predominant factors influencing the sickness rates are primarily emotional in origin. Thus in the twelfth annual report of the Board the following summary is given :—

"Although it has not been found possible as yet to isolate in particular cases the causative factors in sickness absenteeism, there is evidence to support the hypothesis that a high rate may be expected where the following occur: (1) rigidity of conditions; (2) routine work offering few prospects of promotion; (3) clerical as against productive or organising work; (4) badly selected departmental heads; (5) anomalies of payment."

As part of these investigations, Prof. Culpin and Dr. May Smith<sup>3</sup> interviewed over a thousand people of both sexes, in Government offices and commercial firms, factory operatives, people in administrative posts, and students, to ascertain the extent of nervous symptoms among the working population. The value of this investigation is obvious, as it is impossible to generalise about "sick" people until reliable information is available regarding our so-called normal population. Actually they found that some 30 per cent. of these workers showed varying degrees of psychoneurotic symptoms, while some 7 per cent. were in urgent need of suitable treatment for conditions that were crippling their effectiveness in the ordinary business of life. In addition, as they point out,

"there is a tendency for the nervous people to have more sick leave, not necessarily diagnosed as nervous."

The following quotation shows the main outlines of the interviewing technique used :—

"Information with regard to these various attitudes to life was sought from each subject in an interview lasting about 20 minutes. A rigid questionnaire was not used, for the variety of symptoms and their mode of expression is infinite. As the work progressed, however, a general scheme was evolved by which the subject was led through various hypothetical situations that would stimulate the symptoms most commonly encountered. If a subject talked easily he was allowed to follow his own path, questions being interpolated either when he had stopped or when some point required elucidation."

By the use of this method and by inquiring about the individual's reaction to his work, those in authority over him, and his reaction to himself, it was found possible to form a fair estimate of his personality and the degree of neurotic qualities that he showed. Of the 30 per cent. who manifested clinical evidence of neuroticism, the majority were anxiety states, while approximately 12 per cent. were predominantly of the obsessional type; by virtue of the fact that only those actually in a fit condition to be employed were interviewed, frank cases of conversion hysteria were not observed.

#### Manifestations of the Anxiety State

An anxiety state is generally regarded as a manifestation of underlying fear or worry, and is liable to occur when an individual is confronted with difficulties and is unable to meet them in an appropriate adult fashion. It is often fortuitous whether the predominant symptoms are cardiac, gastrointestinal, genito-urinary, or respiratory; further inquiry in such cases will always elicit evidence of generalised dysfunction, although the conscious disturbance may vary in different parts. As Cannon<sup>1</sup> has emphasised, the whole digestive process, which is under the influence of the sympathetic system, may be profoundly deranged by anxiety and distress, with the minor aspects of fear. The natural processes of the alimentary tract are fundamental to all other functions of the body and any disturbance of normal peristalsis, segmentalism, and secretion of the digestive fluids may have widespread ill-effects on the organism. The cardiac system, like the digestive system, is under the influence of the sympathetic nerves, but instead of being inhibited it is stimulated by them. The same sense of fear which stops digestion makes the heart beat more rapidly and raises the blood pressure by contracting the blood-vessels. In this connexion it is of interest that Sir Maurice Cassidy<sup>11</sup> has recently stated that 39 per cent. of the cardiac cases coming under his observation are essentially psychoneurotic in origin. This process of fear is essentially subconscious but the appearance of the physical manifestations permits the mind to neglect the distasteful situation that provoked the symptoms and to concentrate on the outward manifestations that are apparently evidences of underlying illness and, therefore, honourable. The process is strictly comparable to the development of shell-shock during the war among men who were unable to face the continued anxiety associated with the conflicting calls of duty and self-preservation.

Now difficulties are universal while neurotic reactions are fairly uncommon; individuals who fall into the latter category have, due to faulty emotional developments in their early years, acquired the habit of fleeing from their problems rather than of facing and solving them, so that when a particularly difficult situation arises "breakdown" occurs. It follows from this that the main difficulty may arise in any aspect of the individual's life—e.g., in his home, his social relationships, or in his occupation—although it is found in such cases that the adjustment to all these situations tends to rest on a false basis. Under modern economic conditions, with the development of large organisations and the associated likelihood

of personal anonymity, there is an increasing tendency to project the blame for personal disharmony on to the occupation and its concomitant associations, although in my experience the aggravating factors are to be found as often in the home as in the factory or office. It is perhaps not generally realised that physical conditions of employment, at any rate in the more prosperous industries, are improving every year in this country, and I feel that we, as members of this Association and representing the more progressive industries in the country, are entitled to claim some credit for these changes. On the other hand, the breakdown of family ties, the changes in religious influence, and the planless growth of anonymous "housing estates" all bring in their trail problems that throw increasing strain on the mental equanimity of our younger population.

#### Diagnosis of an Anxiety State

It follows from what has been said that a searching anamnesis is indicated which will consider in their true perspective social, occupational, and environmental relationships and the reaction of the individual to his life's situation. Thus inquiries regarding the individual's enjoyment of his work, his reaction to authority, his social contacts, and his reaction to noise, will in a comparatively short while bring to light valuable information for obtaining some insight into the patient's emotional patterns. Such questions cannot be asked pedagogically but are used rather to help him to express himself about significant matters. Elton Mayo,<sup>5</sup> who has recently carried out a most valuable investigation into sources of content and discontent in industrial life, has emphasised the way in which some individuals will pick on one particular problem and in their very insistence on the subject, show its significance in their minds. A complete and painstaking physical examination is as essential here as in all other aspects of medicine, and even when completely "negative" has a comparative therapeutic value as fears of various diseases are a common part of the anxiety state. As a rule the death of a relative from a particular disease will cause the patient to concentrate his attention on the "dis-ease" in the corresponding system in himself. In such cases, as Ross<sup>6</sup> points out, dogmatism is essential and permits of the sympathetic causation being explained to the patient as a necessary preliminary before the emotional factors are discussed.

These various factors are shown very clearly in the following case:—

A typist, aged 25, was seen on account of prolonged absence due to "dyspepsia." Family history negative and childhood free from gross disturbances apart from "night terrors" and somnambulism. In June, 1934, she was absent for two weeks on account of "abdominal rheumatism"; she returned for three days and then changed her doctor, who stated that she had a chronic appendicitis, for which an operation was performed. Microscopic examination of the appendix was negative. She started work again after eleven weeks' convalescence and continued for four months complaining frequently to her supervisor of "indigestion" and "heart burn." In March, 1935, she was absent for a week with "colitis" and again in September, 1935, with "gastritis." She was then seen by a consultant who said it was only "nerves" and she had got to pull herself together. She became much worse after trying to perform this impossible gymnastic feat and when seen in October she was living on peptonised milk and complained of a continued sense of fullness, constipation, nausea, headache, palpitation, and inability to concentrate. As a result of these various symptoms she was convinced that she must have either an ulcer or a new growth. Physical examination was completely negative, except for hyperæsthesia and tenderness over the appendix scar, and evidence of sympathetic over-action in the form of *tâche cérébrale* and dilated pupils. A complete anamnesis revealed the fact that she had been unofficially engaged for eighteen months to a young engineer with an invalid and somewhat possessive mother, but that the question of eventual marriage was

never referred to by his family. An explanation of the method of production of symptoms was given to the patient and the implications of the situation were discussed with the young man. Two days later the girl felt well enough to return to work, the engagement was "officially" recognised, and since that time the patient has not lost a single day, although she still gets occasional palpitation. In addition her supervisor states that she is now "a totally different girl and a really good worker again."

Such a case is essentially a problem in social medicine and illustrates very clearly the way in which anxiety over extrinsic matters, either conscious or subconscious, may manifest itself physically by generalised disturbance of all systems under the influence of the autonomic system. To deal with the somatic symptoms without investigating the causal psychic factors only tends to convince the patient that there must be some obscure disease to cause so much discomfort.

(To be concluded)

#### THE DOCTOR AS DETECTIVE

Dr. L. A. PARRY, of Brighton, took this title for an address delivered at the annual meeting of the Manchester Medical Society on May 6th. His theme was the value of medico-legal and scientific evidence in the detection of crime, especially major crime such as murder. As an example he referred to the Fox case where at the inquest a verdict of death from suffocation by smoke was returned. As the result of suspicions aroused by some remarkable insurance transactions, a further examination was made on the exhumed body of the murdered woman. It was found that there were no sooty particles in the larynx and no carbon monoxide in the blood, both of which should have been present if the cause of death had been suffocation. But there was evidence of death from strangulation. The doctor, acting as a detective, was the means of securing the conviction of a very brutal matricide.

The growth of toxicology was illustrated by three cases—the trials of Mary Blandy in 1752, of Dr. Smethurst in 1859, and of Dr. Crippen in 1910. In the first case, one of the earliest if not the first in which medical evidence was given in a poison trial, Dr. Addington testified to analysing some of the powder which had caused the death of Mr. Blandy, and finding arsenic. No examination of the viscera was made. In the Smethurst case it was pointed out that Dr. Swayne Taylor, the celebrated toxicologist, had at the police-court sworn he had found arsenic in a bottle from the house of the accused. Later he acknowledged the arsenic was contained in the copper gauze he had used for his test. In spite of this terrible blunder, Smethurst was convicted, but afterwards pardoned because of a united outcry of the medical and legal professions in London. In the Crippen case the medical evidence was immensely important, first as regards a mark on the piece of flesh found buried in Crippen's cellar, and secondly through analysis of the viscera found there. The prosecution called evidence that the mark on the piece of flesh was a scar, and as the woman Crippen was charged with murdering had a scar in an identical position, the significance of the mark was of vital importance. For the defence it was contended that the mark was not a scar but simply a fold in the skin, and in support of this claim evidence was given that in microscopic sections a few hair follicles and sebaceous glands were seen. The prosecution rebutted

this, and said that often a small fragment of epidermis was included in a scar, and this would account for the appearances noted. There was no doubt that the mark was a scar. In analysis of the viscera, Dr. Willcox had found a vegetable alkaloid which dilated the pupil. He could exclude cocaine, and that left only three other possibilities, atropine, hyoscyamine, and hyosine. By differential tests he proved it to be hyosine. Crippen had purchased five grains of this drug at a chemist's and could not account for its use. The defence claimed that Dr. Willcox had not proved he had found hyosine. The substance might be a cadaveric alkaloid produced by decomposition. Dr. Willcox said he had employed Vitali's test which differentiated between vegetable and cadaveric alkaloids, and this test was conclusive. A text-book by the doctor appearing for the defence was produced, in which he stated that he regarded Vitali's test as accurate. Why had he altered his opinion? He replied that he had looked further into the matter and had in connexion with this case come to the conclusion that his first view was wrong. This statement necessarily reduced the weight attached to his opinion. Crippen was found guilty and was hanged.

Dr. Parry also referred to the value of the evidence of the doctor in many other cases, such as those in which wounds and injuries of all kinds were inflicted, in workmen's compensation cases, and in the detection of blood stains. In conclusion, he contended that the scientific witness was at least keeping pace with the ingenuity of criminals, and was a potent factor in bringing home guilt to the offender.

#### DESIGN IN NEW BUILDING

THE Minister of Health recently received a deputation organised by the Royal Institute of British Architects on the employment of architects on public building works. The object of the deputation, which was introduced by Lord Crawford, was to request the Minister to bring his influence to bear on local authorities in order to ensure that the large and increasing amount of housing and other building work undertaken by local authorities should be designed and supervised by fully qualified architects.

Sir Raymond Unwin said they were putting forward no suggestion that architects should displace engineers, surveyors, or other men qualified for different branches of work when employed in their proper spheres; the architect was however specially trained in design and planning. In the work to which they were referring there was no conflict between use or efficiency and good appearance; just as in any written statement, there was no conflict between accuracy of fact or soundness of sense and clearness of charm, in the form of expression. The designer, or planner, saw both ends together, but sought to provide for useful purposes in a form which would be orderly, pleasing, or beautiful; all were inextricably bound together. There was in this country a great variety of local conditions, local building materials, and local treasures of ancient buildings erected according to them. This was a national possession, which neither individuals nor local authorities had any right needlessly to destroy. It could only be guarded by the employment of those who had given years of study to the problems of planning and design, which included the satisfying of all practical requirements in a manner that harmonised with the surroundings. They appealed to the Minister to use all the influence at his disposal to secure this end.

Lord Crawford reminded the Minister that in matters affecting the health of the community he always insisted that the best men available should be employed; it was, he said, becoming vitally important that only the best architectural skill obtainable should be utilised on matters of planning and design.

In reply, Sir Kingsley Wood said he fully recognised the desirability of employing professional architects over as wide a field as possible. He was

glad to say that local authorities were more and more employing architects and architectural assistants as permanent officers on their staffs. The architect was, in fact, more and more taking his proper place in combination with the engineer, the surveyor, the doctor, and the housing director in house building. The deputation could rely upon him to use his best offices to secure within the limits of local government good design and good planning. In a circular he was about to address to the local authorities in regard to rehousing for the abatement of overcrowding, he proposed to stress again the desirability of employing skilled architects for designing cottages in rural districts with a view to securing harmonious development. In default of employing an architect, the authorities would be invited to confer with the architect's department of the Ministry at the earliest stages.

#### NEW PREPARATIONS

"NEOKET" COMPOUND MANDELIC ACID GRANULES.—The successful use of mandelic acid in urinary infections depends on keeping the urine acid, and this can be done with ammonium chloride. The objection to ammonium chloride is that it often causes nausea, and in Neoket the Boots Pure Drug Co. Ltd. (Nottingham) replace it by sodium acid phosphate. Their preparation consists of pleasantly flavoured, effervescent granules sweetened with saccharin and containing mandelic acid and sodium acid phosphate, with enough sodium bicarbonate to neutralise the mandelic acid. According to the manufacturers it causes no alimentary upset, and usually makes the urine sterile in 8-10 days; but a little ammonium chloride sometimes has to be taken in addition during the first few days if sufficient acidity is not attained. The dose recommended for adults is two teaspoonfuls (45 grains) four times daily. Fluid intake is limited to a couple of pints a day, and mandelic acid treatment, it is emphasised, should not be given if renal function is impaired.

IMMUNE GLOBULIN (Human) is prepared by Lederle Laboratories, New York, for use as an alternative to "convalescent" or "adult" serum in the prevention, modification, and treatment of measles. They quote observations showing that extract derived from a placenta has the same protective power as the blood of the mother, and since their Immune Globulin extracts are obtained from about 600 placentas the antibody content should be uniform. For prevention of measles it is advised that at least 4 c.cm. should be given; for modification 2 c.cm. is to be injected as soon as a child is known to have been exposed to infection. The injections are intragluteal, and in a small proportion of cases give rise to mild local and febrile reactions. It is stated however that these are rarely produced by the improved preparation now marketed, which is obtainable in this country (in vials of 2 and 10 c.cm.) from Chas. F. Thackray Ltd., Gt. George-street, Leeds, 1.

LYSANTOL, a new fluid antiseptic made by Allen and Hanburys Ltd., London, E.2, is described as "non-corrosive, non-poisonous, and harmless to the skin," though much more powerful than carbolic acid. (Rideal-Walker coefficient, 4.) It has a pleasant smell, leaves no stain, and is miscible with water forming a translucent solution free from scum. It can be applied to wounds without dilution, but for cleansing cuts and abrasions, or for application to insect bites and stings, a tablespoonful in half a pint of water is recommended. In weaker mixtures it serves as a disinfectant appropriate to many surgical and domestic purposes.

A POCKET CAUSTIC HOLDER.—Johnson and Sons (Hendon Way, London, N.W.4) have devised a convenient method of carrying and applying silver nitrate pencils. The Argentic Caustic Holder resembles a small fountain pen; it is neat and compact, and is fitted with a pocket clip. The nitrate pencils

are supplied in glass tubes, each already mounted in a milled cap, which can be screwed into the holder, where it is firmly held until a refill is needed. They are ordinarily made according to the B.P. formula, but other types are also obtainable.

### SPOTLIGHT GOLF

MANY doctors play golf and some play extraordinarily well, though it is quite likely that those get no more amusement out of the sport than the less accomplished exponents. But for all golfers an invention which enables the game to be played indoors will have an interest, and remembering the encroachments upon the time of the medical practitioner, the new invention styled Spotlight Golf may have particular attraction. The invention consists of an electrical apparatus, the motor detector box, to which is attached the ball, while the striker takes up his position a few feet from a screen. The result of any stroke becomes revealed; it is possible to know whether the ball has been truly struck or not, a matter which in the normal game it is only easy to detect at the end of the flight. A record of all shots played with a full set of ordinary clubs is made. The face of the cabinet shows the picture of the hole which is to be played. The length of the shot is indicated along the side of the hole by means of an arrow travelling the number of yards marked which the ball would have reached if played on an actual golf course, and its position is shown within the limits of the fairway by means of a "spotlight"—one player being red and the other white. There are various key lights, and the player whose correct turn it is to play is shown by red or green at the foot of the cabinet. A shot played wide of the fairway is shown by a blue light which calls for another shot by that player. Should the ball finish in a bunker the depth in feet is indicated, and it is only by playing a sufficiently lofted shot that the ball can be properly played out; if this is not done the ball, indicated by a light, remains in the bunker and the player has to continue to play until out of the bunker and until he passes his opponent's ball. The shots being accurately recorded a true picture is obtained of an actual game as played on a natural course.

We congratulate the inventor, Mr. L. J. Simon, on a very ingenious apparatus which is made by the Electrical and Musical Industries, Ltd., 185, Regent-street, London. It seems that there might be a medical use for the invention in providing suitable patients with interesting indoor exercise.

### ILLICIT TRAFFIC IN DANGEROUS DRUGS

THE League of Nations Advisory Committee on Dangerous Drugs have recently had before them a report on illicit transactions and seizures during the first quarter of this year. Clandestine manufactories of narcotics have been discovered in Hong-Kong and Shanghai. In the international settlement in Shanghai it was found that 682 grammes of heroin had been manufactured in three days at a clandestine factory, and a complete laboratory equipment with chemicals was handed over to the Japanese consular police. One of the Chinese persons implicated was sentenced to six years' imprisonment.

Some 30 seizures of raw opium from China, Port Said, and some European and American ports were made; the largest consignment, which was confiscated and destroyed, amounting to 2418 kg., was at Wuhu, China. Prepared opium, mostly in small quantities in the Far East or in America, was reported as having been seized in 29 cases. Last year no less than 10,885 kg. of prepared opium and dross were reported to the secretariat of the League as having been seized. Of morphine ten seizures were reported in the first quarter of this year; the largest amounts were captured at Batavia, Manila, and at Portland, Oregon. Eighteen seizures of heroin were effected, the largest, amounting to more than 6 kg., being at Shanghai. Of cocaine there were sixteen seizures, the largest, of more than 12 kg., was at Prague on

the information of the Government of Czechoslovakia.

The Advisory Committee has been considering the practicability of adopting more drastic measures for the prevention of illicit traffic in dangerous drugs on ocean-going vessels; and the coöperation of seamen's unions for the same purpose was advocated. A report from the secretariat giving estimates of the number of addicts in various countries was withdrawn for further consideration.

**CORRIGENDUM.**—The method of describing hearing aids for the deaf is stated in the notice which appeared on our advertisement page 2 of May 23rd to be covered by British Patent No. 576986. The number should have been given as 376986.

# ADDRESSES AND ORIGINAL ARTICLES

## TREATMENT OF HUMAN PUERPERAL INFECTIONS, AND OF EXPERIMENTAL INFECTIONS IN MICE, WITH PRONTOSIL\*

BY LEONARD COLEBROOK, M.B., B.S. Lond.

MEMBER OF THE SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL

MÉAVE KENNY, M.R.C.S. Eng., M.C.O.G.

RESIDENT MEDICAL OFFICER, ISOLATION BLOCK, QUEEN CHARLOTTE'S HOSPITAL, LONDON

AND THE MEMBERS OF THE

HONORARY STAFF OF QUEEN CHARLOTTE'S HOSPITAL

EARLY in 1935 a startling chemotherapeutic success was announced by Domagk<sup>1</sup> in Germany. Hæmolytic streptococci of human origin were injected into the peritoneum of 26 mice. An hour and a half later 12 of them received by stomach-tube a single dose of a dark red dye, the hydrochloride of 4'-sulphamido-2 : 4-diaminoazobenzol—which had been synthesised by Mietzsch and Klarer (see Hörlein<sup>2</sup>), and all survived, at any rate for seven days. (Their ultimate fate is not stated.) Of the remaining 14 animals which served as untreated controls 13 were dead of their streptococcal infection within three days, and the last 1 on the fourth day. It is of interest to note that some of the treated animals received only 0.02 mg. of the drug—i.e., at least 100 times less than the maximum tolerated dose. So far as we are aware this is the only animal experiment which has been reported from Germany. Domagk described the substance—which was named Prontosil—as showing an "elektive Wirkung" upon streptococcal sepsis but as having some action also on staphylococcal infections in the rabbit.

In France, Levaditi and Vaisman,<sup>3</sup> using a similar compound synthesised by Girard and working with a streptococcus "M" of human origin, obtained curative results in mice which were somewhat similar to those of Domagk but less completely successful. The treated animals did not as a rule survive indefinitely after a single dose of the drug but lived a few days longer than the controls. A little later Nitti and Bovet<sup>4</sup> showed that with hæmolytic streptococci of comparatively low mouse-virulence, freshly isolated from human infections, very little or no curative effect was obtained in mice, while with a strain of high mouse-virulence definite prolongation of life was obtained as in Levaditi and Vaisman's experiments. In their most recent paper Levaditi and Vaisman<sup>5</sup> have claimed that by the subcutaneous administration of a large dose (50 mg.) of prontosil in suspension, mice are frequently protected against a fatal dose of streptococcal culture injected 5-10 days later.

In addition to the reports of animal experiments, there have appeared about a dozen papers in Germany referring to the use of the drug in human infections—e.g., erysipelas, puerperal fever, and so forth (Schreus,<sup>6</sup> Anselm,<sup>7</sup> Schranz,<sup>8</sup> Scherber,<sup>9</sup> Fuge,<sup>10</sup> Kramer,<sup>11</sup> and others). These clinical reports are unanimously favourable, but their evidential value must be regarded as small since, in most cases, the recovery of patients is unhesitatingly ascribed to the treatment, and too

little allowance is made for the tendency to spontaneous cure of these infections. The bacteriological and clinical data supplied are nearly always very scanty—e.g., we are not told whether the cases were all infected by hæmolytic streptococci, whether those organisms were present in the blood before the treatment was commenced, nor in how many of the cases there was present any clinical condition, such as generalised peritonitis, which habitually connotes a very high mortality. The papers do serve, however, to indicate that the drug is well tolerated by the human subject and what dosage has given apparently good results.

### Laboratory Experiments

The following laboratory experiments and clinical trials have been carried out at Queen Charlotte's Hospital.

#### CURATIVE EXPERIMENTS ON MICE

Trials were first made with strains of streptococci freshly isolated from human puerperal infections—i.e., after only two or three passages upon artificial nutrient media.

Mice were inoculated into the peritoneum with an amount of culture which preliminary experiments had shown to contain approximately 10-100 minimum lethal doses. A single dose of prontosil or the more soluble related compound (issued for a time under the name of Streptozon S) was given 1½ or 2 hours after, either by stomach-tube or by subcutaneous injection. In later experiments a series of doses was given—e.g., 1½, 5, 24, 48, 72 hours, and so forth after the injection of culture.

*Results.*—Although occasionally the treated animals survived a little longer than the untreated controls, there were practically no survivals, and the experiments were regarded as negative, failing to confirm Domagk's claim. Six different strains were employed in such tests.

It is important to note that Domagk's original paper refers to two quite distinct substances, both of which gave curative effects in infected mice. The one, prontosil, has the structural formula shown below (I) and is only slightly soluble in water (to 0.25 per cent.); the other, issued for a time under the name Streptozon S, but now as prontosil soluble, is the disodium salt of 4'-sulphamido-phenyl-2-azo-7-acetylamino-1-hydroxynaphthalene 3 disulphonic acid and is represented by the formula (II) below. This is soluble up to 4 per cent.

Formula I

Formula II

In our animal experiments we have used only prontosil soluble obtained from Germany, and the French equivalent of prontosil prepared by Girard. It is possible that the latter substance differed slightly from that used by Domagk in his published experiment. For the clinical trials reported in this paper both substances have been administered to every patient—prontosil by the mouth and prontosil soluble by injection—and both had been prepared in Germany.

\* A preliminary report to the Therapeutic Trials Committee of the Medical Research Council. 5884

TABLE I.—Curative Effect of Prontosil Solubile

	Deaths in each 24-hour period.									
	1	2	3	4	5	6	7	8	9	
4 mice were infected with 4000 streptococci ("Richards") intraperitoneally; and 1½ hours later received 7.5 mg. of prontosil soluble subcutaneously. Further doses were given after 1½ hours, 5 hours, and 1, 2, 3, 4, 6 days.	0	0	0	1	0	0	0	0	0	3 remained well and were killed on 60th day.
4 mice were infected as above; and received prontosil soluble (15 mg.) by stomach-tube 1½ hours later—and also the following day.	1	0	2	1	..	..	..	..	..	—
7 control mice (no prontosil).	1	3	..	..	..	..	..	..	..	—
{ 4 infected with 4000 streptococci (approx.) 3 infected with 400 streptococci .. ..	0	2	0	0	0	0	0	0	0	1 survived.

At this point we were informed by the courtesy of Dr. Buttle, of the Wellcome Physiological Research Laboratories, that he had obtained more success with a streptococcal strain "Williams" which we had formerly isolated from a puerperal fever case and sent to him. This strain differed from those we had previously employed in that it had been transmitted through a series of 23 mice and had acquired a very much higher virulence for those animals. Our next experiments were therefore carried out with a similar highly virulent passage strain "Richards" (a different serological type from "Williams"). With this strain we began at once to get striking curative results in mice, although the animals only survived indefinitely if a series of 6 or 7 doses was given over a period of several days. Typical results are given in Tables I. and II.

*Comment.*—The results shown in these tables—and others like them, not set out here—seem to indicate quite clearly that the administration of the drug does exert some curative effect upon infections by these hæmolytic streptococci in the mouse, which normally terminate in peritonitis and septicæmia. They can be checked in the majority of the animals if treatment is commenced within three hours of the injection of culture. If delayed much beyond that time the death of the animals may be postponed for a day or two but it is not usually avoided. It is of interest to note that one mouse survived after treatment although hæmolytic streptococci were already present in the circulating blood in considerable numbers (a small drop of blood from the tail gave colonies equivalent to 400 per c.cm.) before the drug was administered.

PROPHYLACTIC EXPERIMENTS ON MICE

Mice were injected subcutaneously with 50 mg. of prontosil (kindly supplied by Dr. Girard) in

aqueous suspension (10 per cent.)—and four days later were given a dose of streptococcal culture into the peritoneum. The mice showed no toxic effect of the drug at any time. The results are shown in Table III. It will be seen that whereas 9 out of 12 of the animals which did not receive the drug were dead within three days, only 2 of the 12 treated mice succumbed to streptococcal infection within that period. (Two died somewhat later.)

When the surviving animals were subsequently killed there was a large deposit of undissolved prontosil at the site of injection, and it seems probable that the prophylactic effect shown in the table was due to slow absorption from this depôt. The urine had an orange colour during the whole 26 days after the mice received the drug.

ANIMAL EXPERIMENTS WITH *p*-AMINO BENZENE-SULPHONAMIDE

In view of the discovery by Trefouel and his collaborators<sup>12</sup> (since confirmed by Goissedet and others<sup>13</sup>) that the diazo linkage in prontosil was not essential for its therapeutic efficacy in animals and that the parent sulphonamide (a colourless compound) was equally effective, we have carried out a few experiments with this latter compound kindly prepared for us by Dr. Harold King, F.R.S., of the National Institute for Medical Research.

The curative effect upon infections by the "Richards" strain is clearly shown in Table IV. No prophylactic effect was obtained when 40 to 50 mg. of the drug was given in aqueous suspension subcutaneously four days before the injection of culture. Probably this was due to absorption of the drug from the subcutaneous depôt more rapidly than in the case of prontosil.

TABLE II.—Curative Effect of Prontosil Solubile

	Deaths in each 24-hour period.										
	1	2	3	4	5	6	7	8	9	10	
8 mice were infected intraperitoneally with approx. 2160 streptococci ("Richards") and 1½ hours later received 7.5 mg. of prontosil soluble subcutaneously. Further doses were given after 5 hours, 20 hours, and 2, 3, 4, 6 days.	0	0	0	0	1	2	0	0	0	0	5 remained well and were killed on 42nd day.
6 mice were infected with streptococci as above; and received the first dose (7.5 mg.) of prontosil soluble 3 hours later. Further doses were given after 7½ hours, 24 hours, and 2, 3, 4, 6 days.	0	0	0	0	0	0	0	0	0	?	4 remained well and were killed on 42nd day.
6 control mice { 4 infected with 2160 streptococci (approx.) (no prontosil). { 2 infected with 216 streptococci (approx.)	2	0	1	0	0	0	0	0	0	0	1 survived.
	0	2	0	0	0	0	0	0	0	0	—

TABLE III.—*Prophylactic Effect of Prontosil*

	Deaths in each 24-hour period following infection.							
	1	2	3	4	5	6		
12 mice received 50 mg. prontosil subcutaneously.	6 were infected 4 days later with 396 streptococci ("Richards" strain) into peritoneum.	0	1	0	0	0	1	4 remained well and were killed on 22nd day after infection. (1 had a streptococcal abscess, the other 3 were normal and cultures sterile.) 1 died on 17th and 1 on 20th day. 3 remained well and were killed on 22nd day. (Cultures sterile.)
	6 were infected with 3960 streptococci (same strain).	0	1	0	0	0	0	
12 control mice (no prontosil).	6 were infected with 396 streptococci as above.	0	4	1	0	0	0	1 survived.
	6 infected with 3960 streptococci.	0	4	0	0	0	0	2 survived.

**Upon what Does the Antistreptococcal Influence of Prontosil Depend ?**

Although there can be no doubt as to the curative effects of the drug in mice its mode of action is at present obscure. The chief positive facts which emerge are that multiplication of the streptococci in the peritoneal cavity is prevented, and that this happens quickly—within a few hours. At present it appears very unlikely that the cocci are actually destroyed, either by the drug itself or by some compound formed from it in the animal body.

EXPERIMENTAL DATA

(1) Although the 2.5 per cent. solution used for treatment kills hæmolytic streptococci slowly (1-3 hours) it does not do so if diluted slightly with serum. A tenfold dilution in human serum just prevented multiplication of the cocci; a 1 in 50 dilution allowed multiplication of 57 cocci to 500,000—i.e., very much less than in control serum without prontosil.

(2) The serum of rabbits taken at intervals—e.g., ½ hour, 2 hours, 5 hours, and 24 hours after a large intravenous dose of prontosil soluble (8-10 c.cm.)—was unable to kill even a very small number of hæmolytic streptococci ("Richards" strain). These grew out as freely as in the serum taken before the drug was given.

(3) The serum of puerperal fever patients taken at intervals after doses also showed no bactericidal effect, but the outgrowth of the cocci in such sera was definitely less vigorous than in the serum taken before treatment. Example: 5 cocci of the strain isolated from Case 26 planted in her serum before treatment began grew out by the following day to 54 millions per c.cm. The same implant of cocci in serum taken one hour after the first intravenous dose (20 c.cm.) grew to 4 millions per c.cm. In serum taken two hours after the third dose (20 c.cm. intramuscular) they grew to 650,000 per c.cm. In serum taken on the third day of treatment—one hour after the fourth dose (20 c.cm. intramuscular)—they grew to 100,000 per c.cm. A similar restricted outgrowth was obtained with the sera of two other patients.

It may be noted that this growth-retarding influence of the patients' sera does not come into operation until after the first four hours of incubation.

Nor is there any evidence that administration of the drug promotes more active killing of the streptococci by the whole blood. This has been tested with the defibrinated blood of treated mice and rabbits—the streptococcal population in the bactericidal mixtures being sampled at different intervals—from 1 hour to 24 hours. On no occasion were we able to detect any killing of the "Richards" strain cocci and on several occasions the blood taken after treatment actually allowed more growth than that taken before.

Human leucocytes are but little affected by the drug. A concentration of about 1 in 10 of prontosil soluble, 2.5 per cent., in blood is necessary to diminish their bactericidal activity (as indicated by the killing of staphylococcus in slide cells); and we have failed to find satisfactory evidence that at any weaker concentrations their activity is enhanced.

The leucocyte count of patients and of animals under treatment has shown somewhat variable results.

In two patients out of three at the beginning of their treatment there occurred a rise after the first dose (5600 to 9300 in one; 15,700 to 20,000 in the other) and a subsequent fall towards the original level during the next two days. In the third patient there was a fall after the first dose (14,700 to 10,400) and the lower level was maintained. In two mice and one rabbit the count fell for some hours following relatively large doses (7.5 mg. and 250 mg. respectively).

Apart from the slight growth-retarding influence exhibited by the serum of treated cases there is therefore not much to suggest that either the blood fluids or the blood-cells play a predominant part in checking the invasion of the tissues by the streptococci. Nor have we been able to find any indication that the invasive character of the streptococcus is

TABLE V.—Summary of 38 Cases Treated with Prontosil and Prontosil Solubile

No.	Age.	Pathological condition.	Blood culture.	Day of puerperium.	Prontosil, grammes.			Days of administration.	Result.	Remarks.
					By injection.	Orally.	Total.			
1	28	Local uterine infection with threatened spread to general peritoneum.	—	4th	6	20·4	26·4	12	R	Very ill, S.R.; T. 104°–106°, P. 140–150 for 24 hours; T. normal without further rise after 0·5 g. i.v. (8 c.cm. antitoxic serum also given).
2	29	„ „	—	6th	2	17·2	19·2	4	R	Very ill, S.R.; T. 104°–105°, P. 140–150 for 24 hours; T. normal without further rise on 4th day of treatment.
3	33	Septicæmia with threatened general peritonitis.	+ (a)	5th	3·75	18	21·75	10	R	Very ill, debilitated and anæmic; T. 103°–104° for 5 days. T. and P. normal without further rise, and blood culture negative after 4 days' treatment.
4	30	Local uterine infection.	—	3rd	5·25	25·2	30·45	14	R	Very ill, several rigors, delirium; T. 104°. T. and P. persistently normal after 24 hours.
5	35	„ „	—	4th	4	23·4	27·4	13	R	Very ill, debilitated and anæmic after severe p.p.h.; P. 130–140 for 24 hours, T. over 104°. T. persistently normal after 3 days' treatment.
6	36	Septic endometritis, pelvic cellulitis, and tonsillitis.	—	8th	2·5	17·4	19·9	10	R	Very ill, debilitated, delirious. After admission condition grew worse for 3 days before prontosil. Spectacular improvement, cellulitic mass resolved rapidly.
7	40	Septic endometritis with extensive infected lacerations.*	—	6th	2·5	7·2	9·7	4	R	Condition fair on admission, became steadily worse; T. over 104°. After 1st dose prontosil T. fell rapidly and general condition remarkably improved.
8	40	Septicæmia with pulmonary emboli and multiple metastases.	+	11th	6·25	24·6	30·85	11	R	Very ill. General condition improved steadily; blood cultures negative on 3rd day of treatment. Metastatic abscesses resolved rapidly.
9	30	Pelvic peritonitis threatening to generalise.	—	6th	4·25	18	22·25	10	R	Very ill; T. 103°–104°, P. 120–130 for 48 hours. T. persistently normal after 24 hours' treatment. Threat of general peritonitis rapidly abated.
10	34	General peritonitis.	—	7th	21	23·4	44·4	13	R	Desperately ill. After massive doses of prontosil signs of peritonitis rapidly abated. A very striking result.
11	24	Acute septic endometritis with extensive infected lacerations.	—	4th	5·5	21·6	27·1	12	R	Severe case, drowsy and toxic, S.R. T. and P. fell in 24 hours, but general improvement flagged.
12	29	Pelvic cellulitis, threatened general peritonitis.	—	11th	3·25	27	30·25	16	R	Very ill, S.R. Remarkable improvement in general condition after 24 hours' treatment; signs of peritonitis rapidly disappeared. Treatment suspended too early, cellulitic mass resolved slowly.
13	29	Early generalising peritonitis.	—	7th	1	1·8	2·8	1	R	Very ill. Signs of peritonitis abated within 24 hours. Treatment stopped on account of albuminuria which was present before 1st dose.
14	32	Early generalising peritonitis with septicæmia.	+ (b)	4th	5·5	18	23·5	10	R	Very ill on admission; T. 104°, P. 140, rising; diarrhoea. Spectacular remission of symptoms and signs within 24 hours. Steady improvement followed.
15	28	Local uterine infection.	—	11th	2·5	11·4	13·9	7	R	Very ill on admission; T. 104°, P. 130–140 for 48 hours. Several rigors. T. persistently normal after 2 days' treatment. General improvement striking.
16	31	Acute generalising peritonitis.	—	5th	8	18·0	26	10	R	Ill-nourished woman, very ill. Spectacular and rapid abatement of signs of peritonitis.
17	38	Local uterine infection.	—	11th	3	21·6	24·6	12	R	Moderately severe case; T. 103°–104° for 4 days. T. and P. settled rapidly. No spread of infection.
18	28	Septic endometritis with infected lacerations.	—	4th	2·25	12·6	14·8	7	R	Mild case; T. 102°–103°, P. 110–120 for 5 days. T. and P. settled without further rise 48 hours after administration of prontosil.
19	28	Local uterine infection.	—	5th	2·75	18·0	20·75	10	R	Moderately severe case. T. and P. subsided without further rise on 3rd day of treatment. General condition improved rapidly.
20	21	Local uterine infection and tonsillitis.	—	6th	4·25	18	22·25	10	R	Moderately severe case; T. 102°–103°, P. 120. T. and P. persistently normal in 48 hours.
21	26	Local uterine infection.	—	4th	1·75	13·8	15·55	8	R	Mild case. T. and P. persistently normal after 24 hours' treatment. Rapid general improvement in debilitated patient.

\* Group B, hæmolytic streptococci.

TABLE V.—Summary of 38 Cases Treated with Prontosil and Prontosil Solubile.—(Continued)

No.	Age.	Pathological condition.	Blood culture.	Day of puerperium.	Prontosil, grammes.			Days of administration.	Result.	Remarks.
					By injection.	Orally.	Total.			
22	22	Local uterine infection.	—	3rd	3.75	21.6	25.35	13	R	Moderately severe case, S.R. T. persistently normal after 3rd day of treatment.
23	30	" "	Not done.	5th	1.5	5.4	6.9	3	R	Mild case. Afebrile in 24 hours.
24	26	Acute septic endometritis with infected lacerations.	—	3rd	2	23.4	25.4	13	R	Moderately severe case; flabby, anæmic patient. T. 103°–104°, P. 120–130. T. and P. settled rapidly. General condition greatly improved.
25	30	Pelvic cellulitis.	—	8th	1	9	10	5	R	Very ill on admission. General condition improved rapidly, but prontosil probably stopped too soon. Resolution of cellulitic mass was rather slow.
26	29	Local uterine infection.	—	8th	2.25	11.6	13.85	7	R	Moderately severe case; 7 days' fever. T. subsided rapidly under treatment.
27	39	Septic endometritis with extensive infected lacerations.	—	5th	3.5	16.2	19.7	9	R	Moderately severe case. 5 days' fever.
28	29	" "	—	5th	2.25	14.4	16.65	8	R	Moderately severe case, S.R., rapid resolution of T. and symptoms in 24 hours. Marked general improvement.
29	26	Local uterine infection.	—	5th	2	4.2	6.2	3	R	Moderately severe case, S.R., and severe constitutional symptoms. Prontosil stopped early on account of † toxic effects.
30	34	Pelvic cellulitis, infected lacerations.	Not done.	10th	1.75	6.6	8.35	4	R	Moderately severe case. T. fell within 24 hours of 1st dose.
31	24	Septic endometritis with infected lacerations.	—	8th	2	7.8	9.8	5	R	Moderately severe case. Rapid resolution of signs and symptoms.
32	32	" "	—	12th	1.25	9.0	10.25	5	R	Mild case. Rapid recovery.
33	28	" "	—	6th	5	11.4	16.4	6	R	Moderately severe case. Rapid resolution of signs and symptoms.
34	32	Pelvic cellulitis and extensive infected lacerations.	Not done.	13th	4.5	14.4	18.9	8	R	Late admission, moderately severe case, cellulitic mass already developed. Condition apparently not affected by prontosil.
35	22	Pelvic cellulitis with <i>B. coli</i> pyelitis. †	—	9th	2.5	10.8	13.3	5	R	Large cellulitic mass on admission. Grew worse under prontosil † due to associated pyelitis. Renal symptoms aggravated. Treatment stopped.
36	28	Septicæmia. Thrombophlebitis (ovarian vein).	+	6th	3.75	14.4	18.15	7	D	Extremely severe infection. Blood grew 170 colonies streptococci per c.cm. on admission. No apparent effect of treatment. P.M. showed thrombophlebitis whole R. ovarian vein and pulmonary infarct.
37	30	General peritonitis with septicæmia.	+	11th	2.5	5.4	7.9	4	D	Desperately ill, S.R. General peritonitis probably present several days before admission. No apparent effect of treatment. † inadequate dosage. (Vide No. 10 supra.) P.M. large peritoneal effusion, R. ovarian thrombosis, metastasis.
38	35	Septicæmia, probably thrombophlebitis. No P.M.	+	5th	12.5	25.2	37.7	10	D	Vide end of Note (1) infra.

(a) Before prontosil. (b) On admission. (c) 6 times. † Group G, hæmolytic streptococci. S.R. = Scarlatiniform rash.

changed by contact with the drug or any hypothetical compound formed from it in vivo.

Cocci of the "Richards" strain were suspended for four hours at 37° C. in normal rabbit serum to which prontosil soluble had been added (1 in 8 of the 2.5 per cent. solution); in the same serum without prontosil; and in serum taken from a rabbit which had received 8 c.cm. of prontosil intravenously an hour before. The mouse-virulence of the three samples of cocci remained the same after the four-hour period of incubation.

It has been suggested (Levaditi and Vaisman<sup>14</sup>) that the formation of a protective capsule by the streptococcus is interfered with under the influence of the drug, but this again is not confirmed by our experiments. The virulent "Richards" strain was found to form capsules readily when grown in defibrinated blood. (Wright's stain as recommended

by Seastone.<sup>15</sup>) They were demonstrated just as readily when the blood contained prontosil.

The possibility that the cocci in the treated animals might cease to elaborate certain toxic products which may be directly responsible for death is under consideration, but at present we know of nothing in support of it.

Finally, we have to keep in mind the possibility that the drug activates the reticulo-endothelial system—or some other tissue which may play a vital, but as yet unknown, part in checking invasion by this microbe.

#### Clinical Experiences with Prontosil

In view of the fact that the cure of mouse infections had been obtained only with hæmolytic streptococci

in a condition of unusual virulence, and not in the condition in which they are usually recovered from human infections, it seemed somewhat doubtful whether an analogous curative effect would be exerted in the human subject. But the exact significance of a high mouse-virulence is very imperfectly understood at present and, since all the clinical reports on the treatment of human infections in Germany were very favourable, it was decided to undertake clinical trials on a group of puerperal fever cases all known to be infected with hæmolytic streptococci. (All group A except two.)

The 38 cases summarised in Table V. were all under treatment in the isolation block of Queen Charlotte's Hospital. The list includes every case to whom the drug has been given, with the exception of :—

(1) Mrs. A. B., to whom it was given on admission under the mistaken impression that she would prove to be infected by hæmolytic streptococci. On finding that this was not the case we continued the drug for five days in order to see whether it would affect the course of the fever. It did not appear to do so. She ultimately developed a large abscess of the buttock due to infection by an unidentified anaerobic bacillus (Gram negative).

(2) Mrs. B. C., to whom the drug was given for the same reason as above but discontinued after two days on finding that her fever was due to *B. coli* pyelitis. The temperature had already become normal when the treatment was stopped and remained so.

At first only the more severe cases (10 in number) were treated by prontosil, but during the last few weeks we have included every case (28) infected by hæmolytic streptococci unless there was any contra-indication—e.g., nephritis. No other "specific" treatment has been employed at the same time, except in the case of two patients, Nos. 1 and 11, a single small dose (8 to 10 c.cm.) of antitoxic serum (because they presented an intense scarlatiniform rash). On account of the very severe constitutional disturbance caused by these doses of serum (intravenous) they were not repeated.

*Dosage.*—We have followed the more recent German authors in using rather large doses (actually very much less, weight for weight, than those which give curative effects in mice). At first 20 c.cm. of the 2.5 per cent. solution now issued as prontosil soluble (0.5 gramme) was injected either intravenously or intramuscularly each day, and six tablets per diem, each containing 0.3 gramme of prontosil, were given by mouth. Latterly the amount given by injection in several cases has been increased to 40 c.cm. per diem (occasionally 60 or even 90 c.cm.), and this amount has been diminished pari passu with the clinical improvement of the patient. The total amounts given are shown in Table V.

In view of the sometimes severe, although transient, malaise and nausea induced by the intravenous administration of 20 c.cm. doses we have recently employed this route only for the first treatment and given subsequent doses intramuscularly. Since the drug is absorbed very rapidly it is doubtful whether any advantage is secured by intravenous injection. Intramuscular doses, given rather slowly, cause no pain and have not resulted in any local inflammation or abscess formation.

#### COMMENTARY ON THE 38 CASES SUMMARISED IN TABLE V

*General analysis.*—It behoves us to be very cautious in drawing conclusions as to the curative effect of any remedy upon puerperal infections such as those due to the hæmolytic streptococci in which the exact significance of signs and symptoms is notoriously difficult to assess with accuracy, and in which the prognosis is correspondingly difficult to estimate. At every point it is a matter of fine judgment, instructed by long experience.

Forty-five per cent. of our cases, Nos. 17 to 33 in the table, were judged by us to permit of no conclusion as to the effect of the treatment. All of them would, in all probability, have recovered without the treatment—and perhaps as quickly.

Another group, representing 42 per cent. of the cases (Nos. 1 to 16), left us with the impression that the drug had in all probability hastened or determined recovery from the infection. All these were cases which undoubtedly presented signs and symptoms of septic infection so severe as to give ground for anxiety; and cases which, in the light of our previous experience over several years, surprised us by the prompt clinical improvement and remission of fever following the first few doses of prontosil. It is worthy of note that the average age of this group was 31.8 years.

Three of the cases of this group, Nos. 10, 14, and 16, were of specially great evidential value. Although exploratory laparotomy was not performed there was good reason to suppose that in all 3 cases the infection had already involved the general peritoneal cavity (abdominal as well as pelvic) and was quickly becoming diffuse. Case 14 had, in addition, a few streptococci in the blood stream—a circumstance which made the prognosis extremely grave. In this latter case, and in Case 16, the indications of diffuse peritonitis disappeared within 48 hours, and in Case 10 a little more slowly, after the beginning of treatment by very large doses of prontosil (60 c.cm. per diem, by injection, as well as six tablets by mouth for the first few days. In view of the generally recognised gravity of this condition—and taking into account the fact that all three women were over 30 years of age—it appears to us very unlikely that they would have made a spontaneous recovery. In 5 other cases of this group there were indications on admission that a spread of infection from the pelvic to the abdominal peritoneum was beginning. Those indications quickly disappeared.

The clinical course of 5 cases, Nos. 34 to 38, did not run so smoothly. In 2 of them who recovered (Nos. 34 and 35) we had a suspicion that the treatment might be exerting an unfavourable effect, and in 1 of these (infected by a group G streptococcus) improvement did set in as soon as the drug was discontinued. The other case, No. 34, did not come under treatment till the thirteenth day of the puerperium, with cellulitis already developed. She was a very neurotic subject. Cases 36 and 37 who had an overwhelming infection on admission—a heavy septicæmic invasion in the one and a fully developed diffuse peritonitis (probably of several days' standing) in the other—showed no apparent effect of the treatment one way or the other. It may be noted that in neither of these cases did we employ the heroic doses which seemed to give an unexpectedly good result in Cases 10, 14, and 16. The post-mortem findings of Case 36 suggested that she might possibly have recovered had we done so.

The last case (No. 38) of very severe septiciæmia without peritonitis does not allow of any definite conclusion as to the influence of the prontosil. Treatment began within two days after the first rise of temperature (the blood then growing 40 colonies of streptococci per c.cm.) and was continued very vigorously for seven days, but the temperature did not fall satisfactorily and streptococci were grown again from the blood on three more occasions (60, 12, and 96 per c.cm.). After eight days, although her general condition remained remarkably good, she became exhausted by the frequent large injections (20 c.cm., t.d.s.) and the drug was discontinued.

altogether. In all probability her septicæmia was attributable to an extensive thrombo-phlebitis—streptococci being continually thrown off into the blood stream from the breaking down blood-clot. It is hardly to be expected that any chemotherapeutic agent can come into effective operation upon the microbes in such a focus. After an interval of seven days, during which her condition grew worse and her blood gave three more positive cultures, she was given two still larger doses (100 and 150 c.cm. by intravenous drip with a 24-hour interval), but she died on the sixteenth day.

#### MORTALITY-RATES OF TREATED AND UNTREATED CASES

There have been 3 deaths in the 38 cases treated by prontosil—that is 8 per cent. In considering the significance of this figure it has to be borne in mind that the first 10 cases were chosen because they were severe or moderately severe cases—the mildest being deliberately excluded; and, further, that the death-rate fluctuates to some extent according to whether few or many late cases—particularly late peritonitis cases—are admitted to the hospital. The following figures give an idea of the usual mortality-rate for *all* cases admitted to the isolation block and found to be infected by hæmolytic streptococci.

In the 38 cases admitted immediately prior to the use of prontosil (August to December, 1935) there were 10 deaths—i.e., 26.3 per cent. In the 38 cases immediately preceding these (March to July, 1935) there were 9 deaths—i.e., 23.7 per cent. During the four years 1931–34 the rate varied between 18 and 28.8 per cent. (average 22 per cent.).

While, therefore, there would appear to have been a very considerable reduction of the death-rate among the prontosil-treated cases it would be unwise to assume on the basis of so small a series that the reduction will be maintained. Nevertheless we are of the opinion that the very low death-rate, taken together with the spectacular remission of fever and symptoms observed in so many of the cases, does suggest that the drug has exerted a beneficial effect. It may be added that there is no reason to ascribe the clinical results to any other change in the local or general treatment of the cases.

#### TOXIC AND OTHER EFFECTS ASSOCIATED WITH THE TREATMENT

A remarkable feature has been the sensation of burning, chiefly located in the infected tissues, which is experienced by some patients (not by all) during the intravenous injection of 10–20 c.cm. of prontosil soluble. This was particularly well marked in the case of a medical man suffering from acute streptococcal sepsis of the hand. As previously stated, a number of patients have also experienced a rather unpleasant feeling of faintness and nausea (and sometimes an urgent desire to defæcate) for a few minutes following the intravenous injection of 20 c.cm.—not intramuscular injection. In the case of the medical man just referred to there was a much more prolonged feeling of ill-being but this has been quite unusual. The skin has acquired a slightly red or terra cotta tinge in several of the cases who received large doses of the drug.

The urine is always deeply tinged by the dye during the treatment and, contrary to the experience of the German authors who have reported upon clinical trials, many of our cases have given evidence of a mildly irritant effect upon the urinary tract tissues. About 75 per cent. of them have

shed epithelial cells in varying numbers at some time during the treatment; a much smaller number (40 per cent.) have passed red blood-cells and a few of them also casts. Case 10, who received 44 grammes of the drug, had a considerable number of casts, red blood-cells, and epithelial cells towards the end of the treatment. The casts disappeared within a week but the red cells persisted somewhat longer.

In 70 per cent. of the cases treated no albumin was found in the urine during treatment, or there was no increase of the trace originally present. Twenty per cent. showed a slight increase of the albumin (a trace) originally present—or developed a trace under treatment.

Ten patients (8 of them from the Group 1–16 who had received fairly large doses of the drug) have shown no indications of renal or other ill-effects on routine examination 3–5 weeks after discharge from the hospital.

The most striking toxic manifestation has been the development in 3 recent cases of cyanosis—associated with sulphæmoglobinæmia.

In No. 30 the condition was first noticed on the third day of treatment, after she had received only 4.0 grammes of prontosil. As the possible connexion with the drug was not at first suspected she received treatment for three more days, the cyanosis becoming all the time more intense, but unaccompanied by any increase of the respiratory rate or subjective symptoms. No active treatment for the cyanosis was adopted, and it diminished very much within ten days after the discontinuance of prontosil.

No. 31 had been under treatment for five days (9.8 grammes in all) when the cyanosis first attracted attention, and like the other case had made a good recovery from a mild infection. Her cyanosis was never so deep as that of No. 30.

No. 33, another case of mild uterine infection, had received 16.4 grammes of prontosil during six days' treatment before the cyanosis was noticed. She also showed no respiratory embarrassment or other symptoms.

Spectroscopic examination of the blood of all 3 cases by our colleague, Dr. A. T. Fuller, showed the presence of sulphæmoglobin.

The association of this condition with the taking of an azo dye recalled the description of some similar cases by van den Bergh and Revers<sup>16</sup> following the administration of pyridium. These authors suggested that the simultaneous taking of magnesium sulphate in their cases might have contributed to the development of sulphæmoglobinæmia. Whether this hypothesis can be substantiated we do not know, but as a matter of fact we found on inquiry that all of the prontosil-treated cases had also been taking magnesium sulphate.

It is too early yet to assess the importance of the sulphæmoglobinæmia in the affected cases. A note with regard to their subsequent history, and as to the occurrence of any fresh cases, will be submitted later.

#### SURVIVAL OF HÆMOLYTIC STREPTOCOCCI IN PRONTOSIL-TREATED CASES

In about 60 per cent. of puerperal fever cases infected by hæmolytic streptococci these organisms continue to be present in the discharge from the uterus for at least three or four weeks—sometimes much longer. Routine examinations have shown that they persist for approximately the same length of time in the prontosil-treated cases.

#### Summary and Conclusions

(1) A single dose of prontosil or prontosil soluble given by stomach-tube or subcutaneous injection did

not suffice to save mice infected 1-2 hours earlier with hæmolytic streptococci (group A), but subcutaneous injection repeated daily for six days was usually effective—even against 100 to 1000 minimum lethal doses.

(2) Such curative effects in mice were only obtained against hæmolytic streptococci of very high mouse-virulence; they were not obtained with 6 strains of medium or low mouse-virulence, freshly isolated from human infections.

(3) A large subcutaneous dose (50 mg.) of prontosil in suspension protected mice against infection four days later with the highly virulent streptococcus. Protection after a longer interval was not tested, but absorption of the drug from the subcutaneous depôt continued for at least three weeks, as judged by discoloration of the urine.

(4) Curative effects in mice (but not prophylactic effects) similar to those obtained with prontosil were obtained by repeated injections of the colourless compound, *p*-aminobenzenesulphonamide.

(5) Thirty-eight puerperal fever cases infected by hæmolytic streptococci have been treated by oral plus intravenous or intramuscular doses of prontosil. Subject to confirmation by further experience the impression has been gained that in many of the more severe cases the drug has exerted a definitely beneficial effect, manifested by unexpectedly prompt fall of temperature and remission of symptoms; and this impression is supported by a substantial reduction in the case-mortality of the whole series. Three patients in whom there was judged to be a generalising peritonitis on admission (one with a positive blood culture) have recovered without laparotomy under very large doses of the drug. The clinical results, together with the mouse-protection experiments, support the view that further clinical trial is amply justified, and that there is more hope of controlling these streptococcal infections by the early administration of this or some related chemotherapeutic agent than by any other means at present available.

(6) While the drug has been well tolerated by most of the patients there have been transient toxic effects in some cases, and many have shown indications of a mildly irritant effect upon the tissues of the urinary tract. Three cases have developed sulphæmoglobinæmia.

(7) There is at present no indication from animal experiments that the drug is likely to have a beneficial effect upon puerperal infections by organisms other than the hæmolytic streptococci; and in view of the toxic effects referred to above its administration should be confined to such cases.

(8) Apart from the fact that growth of the streptococcus is somewhat retarded (*although not suppressed*) in the serum of patients under treatment by the drug very little is known at present as to the nature of its antimicrobial influence in the animal body. On the one hand the invasive character of the streptococcus seems to be unchanged by contact with the drug or the serum of treated animals; and, on the other hand, there is no evidence of any "immune-response" being evoked by it.

The prontosil used in this clinical investigation was supplied to the Therapeutic Trials Committee by Messrs. Bayer Products Ltd., to whom acknowledgments are due.

## PROTECTION OF MICE AGAINST STREPTOCOCCAL AND OTHER INFECTIONS BY *p*-AMINOBENZENESULPHONAMIDE AND RELATED SUBSTANCES

BY G. A. H. BUTTLE, M.A. Camb., M.R.C.S. Eng.

W. H. GRAY, M.Sc. Wales

AND

DORA STEPHENSON, Ph.D. Leeds

(From the Wellcome Chemical Research Laboratories,  
London, and the Wellcome Physiological Research  
Laboratories, Beckenham, Kent)

MANY attempts have been made to protect animals against bacterial infections by means of antiseptic drugs. The most successful of them was that of Morgenroth and Levy<sup>1</sup> who showed that ethyl dihydrocupreine (Optochin) would protect mice infected with pneumococci. Protection against streptococci had not been demonstrated until Domagk, who was working with azo-dyes, noticed that the presence of a sulphonamide group, while lessening the efficiency of the dye as an antiseptic in vitro caused it to protect infected mice (Hörlein).<sup>2</sup> In 1935 Domagk<sup>3</sup> reported a very notable effect with one of these dyes, the hydrochloride of 2:4-diaminoazobenzene-4'-sulphonamide (Prontosil, formula I.). One dose varying from 0.02 to 10 mg. given an hour and a half after infection was effective against a lethal dose of one strain of streptococcus inoculated into the peritoneum. Domagk showed that scrapings of peritoneum taken 48 hours after infection were free from cocci in treated mice, whereas large numbers of cocci were present in the controls. In a later paper the same author<sup>4</sup> states that the administration of 1/10 to 1/50 of the tolerated dose (0.2 to 1 mg.) for three to five days after infection protects most of the mice, and that some less acute infections could be controlled with 1/100 to 1/500 of the tolerated dose.

Levaditi and Vaisman<sup>5</sup> confirmed the results of Domagk, but they were not able to protect every treated mouse, although all the mice showed delay in the time of death. These authors noted that the dye was not active against the staphylococcus, the paratyphoid bacillus, bacillus pseudotuberculosis, or Friedländer's bacillus. They showed that the cocci could be recovered from the spleen of the treated animals up to the eighth day after infection, but that if the animals lived longer than this the spleens were sterile. Nitti and Bovet<sup>6</sup> confirmed the general result, but they could not protect every mouse; they found that

10 <sup>-5</sup>	50,000		0	1	4	0	0	1	2	

The drugs were given by the mouth immediately after infection; the same doses were repeated 8 times: 7 hours, 1, 2, 3, 4, 6, 9, and 12 days after infection.

mice were not protected against strains of low virulence by the drug. J. et Mme. Trefouel, Nitti, and Bovet<sup>7</sup> noticed that azo-compounds which did not contain a sulphonamide group attached to one benzene nucleus were inactive, whereas the substituent groups in the other nucleus could be varied considerably without influencing the protective power; this led them to the conclusion that the animal was able to break down the compounds with the formation of *p*-aminobenzenesulphonamide. They showed that *p*-aminobenzenesulphonamide hydrochloride had an action similar to that of the azo-dye (prontosil) derived from it in protecting mice. Goissedet, Despois, Gailliot, and Mayer<sup>8</sup> confirmed the conclusion of J. Trefouel that the azo-linkage was not necessary for this action on streptococci; they found that benzylidene-aminosulphonamides were active, also sodium *p*-aminobenzenesulphonamidemethylenebisulphite.

Experimental \*

Confirming the results of Trefouel, Nitti, and Bovet, we found that the hydrochloride of *p*-aminobenzenesulphonamide has an action on infected mice which is similar to that of prontosil. The compound was found to be freely soluble in water, but the resulting solution was acid and produced a local necrosis when given by subcutaneous injection. To avoid this effect *p*-aminobenzenesulphonamide base has been used in these experiments.

The toxicities of prontosil and *p*-aminobenzenesulphonamide base and hydrochloride were compared, giving the drugs in a suspension of gum acacia by the mouth to mice of 19 to 22 g. weight.

12 mg. of prontosil was innocuous, 25 mg. killed four out of six mice, 50 mg. five out of six, and 100 mg. six out of six. With *p*-aminobenzenesulphonamide base or hydrochloride, 50 mg. was innocuous, 100 mg. killed two out of six mice, and 200 mg. six out of six. Larger doses of prontosil (50 mg.) were tolerated if given subcutaneously.

In the therapeutic experiments, the strain used was

\* G. A. H. Buttle and D. Stephenson are responsible for all the experiments on animals.

a mouse-virulent hæmolytic streptococcus obtained from a case of puerperal septicæmia ("Richards") by Dr. Colebrook; it has been repeatedly passaged through mice. The cocci were grown for six hours in a broth described by O'Meara and Brown.<sup>9</sup> Dilutions of the culture were made in broth so that 0.3 c.cm. could be used for each intraperitoneal injection. For a comparison between different drugs it is necessary to use mice infected at the same time, as streptococci grown under apparently identical conditions vary somewhat in virulence.

The drugs were given by the mouth immediately after infection and the doses repeated every day for three days or more; this method of administration has been found to give the maximum protective effect. In our original experiments, mentioned in THE LANCET (1935, ii., 840), when one dose only was given—as in Domagk's original experiment—a prolongation of life of about two days only was obtained.

Table I. gives a representative example of a series of these therapeutic experiments. In all of them prontosil and *p*-aminobenzenesulphonamide are equivalent in protective activity with doses of 2 mg. With larger doses the toxic action of prontosil interfered with the comparison of therapeutic efficiency. The drugs also protect when injected subcutaneously. The protection shown with *p*-aminobenzenesulphonamide is better than that obtained with prontosil. †

The efficacy of a drug for protecting against streptococcal infection can be assessed by two criteria: (1) an estimate of the number of average lethal doses of cocci against which the drug will protect when it is given to the infected mice under optimal conditions for its action; and (2) by an estimate of the latest

† The prontosil referred to is the hydrochloride of 2:4-diaminoazobenzene-4' sulphonamide. Prontosil soluble is a different substance—preliminary experiments indicate that it protects as well as *p*-aminobenzenesulphonamide.

TABLE II.—Protection of Mice against Streptococcal Infection by *p*-Aminobenzenesulphonamide

Infecting dose (c.cm.)	Approx. number of organisms.	Treatment.	Number of mice out of a total of 6 injected dying on each day after infection.											Survived 1 month.

			Treated.	0	0	1	2	0	0	0	0	0	0	0	0	0

The treated mice had 5 mg. of *p*-aminobenzenesulphonamide subcutaneously immediately after infection; the dose was repeated 5 hours later and again every day for 6 days. k. = killed.

time after infection when administration of the drug will still be operative in saving these animals. The action of *p*-aminobenzenesulphonamide base in protecting mice inoculated with multiple fatal doses of streptococci is shown in Table II., which also shows the effect of giving the drug at different times after infection. The lethal dose of culture for untreated mice is 10<sup>-9</sup> c.cm. (this dose kills 4/6 of the mice and should more properly be called the "2/3 lethal dose"). The drug will protect mice infected with 10,000 lethal doses of cocci. If a million lethal doses are used for the infection, the treated mice die at similar times to the untreated controls receiving one lethal dose. Protection can be demonstrated if the drug is given by the mouth to mice eight hours after infection; the drug protected 4 mice which had no cocci in the blood at the time of treatment, delayed for five days the death of a mouse with 500 cocci per c.cm. and failed to protect another with 3000 per c.cm. of blood.

If the drug was given 19 hours after infection, 1 out of the 6 mice were saved and the death of the the others delayed slightly.

EFFECT OF *p*-AMINO BENZENESULPHONAMIDE ON DIFFERENT STRAINS OF STREPTOCOCCI

The protective action of the drug has been tested with six different strains of virulent streptococci. The results are shown in Table III. The first four strains used in this experiment were mouse-virulent streptococci obtained from cases of puerperal sepsis by Dr. Leonard Colebrook, the last two, C.203,

a scarlet fever strain, and "Aronson" (Schnitzer) strains were obtained from Dr. E. W. Todd. They are all Group A strains by the Lancefield classification, although belonging to different serological types as shown in Table III., they have all been repeatedly passed through mice.

The puerperal strains and C.203, the scarlet fever strain, all give the same results as the "Richards" strain used for the experiment in Table I. It is evident that protection can be obtained equally well against streptococci of different serological types. Protection against the "Aronson" strain can only be obtained if a very small dose is used for the infection. Protection against a Lancefield Group B strain "Aronson" (Neufeld) has been obtained by Dr. Colebrook (personal communication): 7.5 mg. of prontosil or *p*-aminobenzenesulphonamide injected daily protected mice against 100 fatal doses of this strain.

EXPERIMENTS WITH ORGANISMS OTHER THAN STREPTOCOCCI

Experiments with *staphylococci* have so far failed to show any protection. The staphylococcal strains available will only kill mice with a very large dose, and it has already been shown that there is no protection with a large dose of a relatively avirulent streptococcus (Nitti and Boyet).<sup>6</sup>

Some preliminary protection experiments with mice infected with *meningococci* done in coöperation with Mr. H. Proom have given favourable results. The organisms were injected intraperitoneally in a suspension of 5 per cent. mucin as described by

TABLE IV.—Protection of Mice against Meningococcal Infection by *p*-Aminobenzenesulphonamide

No. of organisms.	Treatment.	Number of mice out of a total of 10 injected dying on each day after infection.						Survived 1 month.
		1st	2nd	3rd	4th	5th	6th	
10,000	Untreated.	5	2	0	1	0	0	2
	Treated.	0	0	2	0	0	0	8
1 million.	Untreated.	1	4	5	0	0	0	0
	Treated.	0	0	0	0	0	0	10
100 million.	Untreated.	4	6	..	..	..	..	0
	Treated.	0	2	3	0	0	0	5

The meningococci were injected intraperitoneally in a suspension of 5 per cent. mucin. The treated mice received 5 mg. of *p*-aminobenzenesulphonamide base immediately after infection; the dose was repeated 8 hours later and again every day for the first three days.

Miller.<sup>10</sup> Table IV. shows that the degree of protection with one strain of meningococci (Type II.) is of the same order as that with streptococci. Protection against another strain of lower virulence was also obtained. Further work with several strains is required.

Against *pneumococcal* infection (*pneumococcus* Type I.) the drug has little effect; it is only just possible to demonstrate a slight effect with a very small infective dose of the cocci.

acid (cf. Stewart<sup>11</sup>) but this reaction was found to be not a general one. New compounds are marked with an asterisk. The preparation of 2:4-diaminoazobenzene-4'-sulphonamide (formula I.) was postulated in English Patent No. 149,428/1920, but actually described for the first time in E.P. 430,580/1935. The specimen made for the purpose of the present tests conformed in melting-point with the figure given in the patent, and had the same therapeutic action as the commercial material.

TABLE V

† This substance has been previously described (Heidelberger and Jacobs<sup>12</sup>) as having an indefinite decomposition point at about 190°. The other four cinchona alkaloid derivatives mentioned in this paper behave similarly. ‡ Compare discussion.

The following had only a trace of therapeutic activity: *p*-Sulphonamidobenzeneazodihydrocupreidine, \**p*-Sulphonamidobenzeneazoquinoline, \**p*-Sulphonamidobenzeneazo-isoapoquinine, \**p*-Sulphonamidobenzeneazoisoapoquinidine, \**p*-Toluenesulphonamido-phenylhydrazine-*p*-sulphonic acid. (\* = new compounds).

The following were inactive: Benzenesulphonamide, *p*-Aminoacetanilide, *p*-Hydroxybenzenesulphonamide, *p*-Chlorobenzenesulphonamide, *m*-Aminoacetanilide, *o*-Nitroacetanilide, *m*-Nitroacetanilide, *p*-Nitroacetanilide, 2:6-Dibromo-1-aminobenzene-4-sulphonamide, 1-Aminobenzene-2:4:6-trisulphonamide, *p*-Toluenesulphonamido-phenylhydrazine, Sodium benzenesulphonate, 4-Nitro-1-aminobenzene-2-sulphonic acid,  $\alpha$ -Naphthalenesulphonamide,  $\beta$ -Naphthalenesulphonamide,  $\alpha$ -Naphthylamine-5-sulphonic acid, Sodium  $\beta$ -Naphthylamine-1-sulphonate.

The drug has been tried without effect for protecting against *Trypanosoma equiperdum* in mice and against malarial infection in canaries.

### Substances related to *p*-aminobenzenesulphonamide

The success attained with these simply constituted compounds naturally directed attention to the study of others more or less closely related to them, with the object of obtaining a clue to the chemical structure requisite for the development of this form of bactericidal activity. Trials of a number of readily available substances were made (Table V.).

In this Table the constitution of the substance dealt with is indicated in column 2 by the formulæ of the substituents, numbered in accordance with the orientation shown in the typical formulæ at the head of the Table. Thus, in the case of *p*-sulphonamidobenzeneazodihydrocupreine (No. 5), the -NH<sub>2</sub> group in position I. of formula II. is replaced by the azodihydrocupreine group, -N=N-C<sub>10</sub>H<sub>11</sub>O<sub>2</sub>N<sub>2</sub>, the sulphonamide group in position 4 remaining unchanged.

In the preparation of some of these substances, the intermediate sulphonyl chlorides were with advantage made directly by means of chlorosulphonic

The results obtained were as follows:—

(A) *Substances in which the amino group -NH<sub>2</sub> in position 1, formula II., was modified or replaced.*—Replacement of the -NH<sub>2</sub> group by -NH-CO-CH<sub>3</sub>, -N(CH<sub>3</sub>)-CO-CH<sub>3</sub>, and -CH<sub>3</sub> produces compounds with considerably less activity. A series of azo-compounds in which -NH<sub>2</sub> was replaced by -N=NR, where R is the dihydrocupreine, dihydrocupreidine, apoquinine, isoapoquinine or isoapoquinidine residue, or =N-N=R', where R' is the tropinone residue, all proved to be only slightly active, as did an azo-compound in which R was the protein of mouse-serum. Replacement of the -NH<sub>2</sub> by -H, -OH, or -Cl, produced inactive compounds.

(B) *Substances in which the sulphonamide group in position 4, formula II., was modified.*—Substitution of -C<sub>6</sub>H<sub>5</sub> for one of the hydrogen atoms of the sulphonamide group produced a compound (*p*-aminobenzenesulphonanilide No. 7) as active as *p*-aminobenzenesulphonamide; the acetyl derivative was less active. Sulphanilic acid, No. 9, containing the group -SO<sub>2</sub>-OH in place of -SO<sub>2</sub>-NH<sub>2</sub>, was only one-twentieth as active. Modification of either group attached to the benzene nucleus diminished or destroyed the activity, with the surprising exception of the anilide. The possibility that anilide group had some specific action of its own led us to examine *m*- and *p*-aminoacetanilide and *o*-, *m*-, and *p*-nitroacetanilide, but all of these proved to be very toxic, and showed no action in tolerated doses.

(C) *Introduction of additional substituents into the benzene nucleus, formula II.* (Footnote to Table V.).—Two

bromine atoms, in the 2 and 6 positions, gave an inactive compound. 1-Aminobenzene-2 : 4 : 6-trisulphonamide was also inactive.

(D) *p*-Toluenesulphonamide derivatives, formula II. (Footnote to Table V.).—*p*-Toluenesulphonethylamide was less active than *p*-toluenesulphonamide, and the corresponding diethyl-compound was inactive.

(E) *Sulphonic acids, formula II.*—*m*-Aminobenzenesulphonic acid was slightly active. Sulphanilic acid has been mentioned above. Phenylhydrazine-*p*-sulphonic acid had a slight activity. Benzenesulphonic acid and 4-nitro-1-aminobenzene-2-sulphonic acid were both inactive. The presence of the basic group ( $-NH_2$ ) attached to the benzene ring appears to be more important than that of the sulphonamide group alone.

(F) *Naphthalene derivatives, formula III.*— $\alpha$ - and  $\beta$ -Naphthalenesulphonamides were both inactive;  $\alpha$ -acetylamino-naphthalene-4-sulphonamide active, but not quite as good as the corresponding benzene derivative.  $\alpha$ -Naphthylamine-4-sulphonic acid (tested as sodium salt) had the same degree of activity as sulphanilic acid, the benzene analogue.  $\alpha$ -Naphthylamine-5-sulphonic acid and  $\beta$ -naphthylamine-1-sulphonic acid (sodium salt), on the other hand, were quite inactive.

### Summary

1. *p*-Aminobenzenesulphonamide will protect mice against streptococcal infection. It has the same therapeutic activity as prontosil, but is less toxic when given by the mouth, so that it is possible to obtain better protection by giving larger doses.

2. Protection can be obtained against streptococci belonging to different serological types.

3. Some protection of mice against meningococcal infection has been demonstrated, but it has not been possible to demonstrate protection against staphylococci or pneumococci.

4. Increase in the number of sulphonamide groups attached to the benzene nucleus to three is accompanied, not by increase, but by extinction of the streptococcid activity.

5. The anilide of sulphanilic acid is as active as the amide.

6. Sulphanilic acid itself has a smaller, but not negligible, protective action.

7. Azo-compounds derived from *p*-aminobenzenesulphonamide and phenolic cinchona alkaloids are inferior to prontosil in this respect.

We have pleasure in acknowledging our indebtedness to Dr. T. A. Henry and Dr. Colebrook for the interest which they have taken in this work and for many helpful suggestions; to Mr. A. W. Chapman for much help in the preparation of the substances; and to Mr. N. McLaren and Miss J. Smith for assistance with the animal experiments. We have to thank Dr. Colebrook and Dr. Todd for the supply and serological typing of the strains of streptococci.

## A MACROSCOPIC AGGLUTINATION TEST IN WEIL'S DISEASE

BY A. W. POT, M.D.

OF THE NATIONAL INSTITUTE FOR PUBLIC HEALTH, UTRECHT

NONE of the methods described for the serological diagnosis of Weil's disease—Schüffner's agglutination and lysis test, Bessemans's and Gaeltgens's complement-fixation tests, and the adhesion test of Brown and Davis—is anywhere near as simple as Widal's reaction for typhoid.

The preparation of the antigen for Gaeltgens's complement-fixation test, in which a culture of leptospiræ is centrifuged and the sediment suspended in saline containing 0.3 per cent. carbolic acid, induced me to try whether a similar, definitely turbid reagent would give a *macroscopic* agglutination with anti-serum.

Since carbolic acid dissolves the leptospiræ, the sediment from about 250 c.cm. of Korthof's liquid medium was suspended in 10 c.cm. of meat broth (pH 7.6) to which 0.2 per cent. of commercial formalin was added. This suspension was kept in the ice-chest and thoroughly shaken each day for a week; it was then brought to the required density by the addition of saline and 0.2 per cent. formalin.

In order to save antigen, narrow tubes were used for the reaction, of such a size that 0.25 c.cm. of dilute serum with an equal volume of leptospira suspension gave a sufficiently high column of liquid. The serum was diluted in a series of larger tubes (1:25, 1:50, 1:100, &c.); 0.25 c.cm. was taken from each of the dilution tubes by means of Dreyer's pipette, and introduced into the testing tubes with 0.25 c.cm. of the reagent. The series of tubes were then placed for 2 hours in a water bath at 52° C.; less satisfactory results were obtained when they were kept for 2 hours in an incubator at 37° C.

The control tube, containing 0.25 c.cm. of saline solution and 0.25 c.cm. of leptospira suspension, always showed a fine granulation, which was readily observed with a magnifying glass against a dark ground. Probably the dimensions of the leptospiræ, which are much greater than the bacteria that we are usually concerned with in agglutination tests, are responsible for this phenomenon. This condition does not interfere however in a *weak* agglutination, if the test and control tubes are compared with one another.

Sera from 26 patients positive to Schüffner's agglutination and lysis test were examined; in 20 of these cases it was also known that the complement-fixation test was positive. The sera were kept in the ice-chest without preservative, sometimes for longer than 6 months, without apparent deterioration. The macroscopic agglutination test was positive in 25 cases; the titres varied between 1:50 and 1:51,200. One serum (agglutination and lysis test positive at 1:1000; complement-fixation test positive at 1:320) gave a negative result.

Of 15 sera sent in for a Wassermann reaction, all gave negative results to this test; the smallest dilutions at which these controls were examined were 5 sera at 1:50 and 10 sera at 1:20.

Although the preparation of the suspension is a simple matter, one must not underestimate the difficulties which the cultivation of large quantities of leptospiræ can offer. Whether or not the macroscopic agglutination test will become of practical importance depends, among other things, on whether an institute provided with all the necessary equipment will be prepared to undertake the preparation of the reagent in quantity and put it at the disposal of laboratories. If such a suspension is made available, the carrying out and the reading of this macroscopic agglutination test is as simple and also as harmless as that for typhoid with Ficker's reagent.

## LATE RESULTS IN THE OPERATIVE TREATMENT OF INTRACRANIAL TUMOURS

BY HUGH CAIRNS, M.B. Adelaide, F.R.C.S. Eng.

SURGEON IN CHARGE OF THE DEPARTMENT OF NEURO-  
SURGERY, LONDON HOSPITAL

(Concluded from p. 1228)

### REGIONAL CLASSIFICATION OF THE RESULTS

So far the results have been considered according to the pathological type of the lesion without taking into account its site. Certain types of tumour tend to favour particular sites of origin, yet in most instances their predilection for such sites is not constant enough to be reliable for prognosis. With a clinical syndrome of tumour in the cerebello-pontine angle the probability is very great that the tumour will prove to be an acoustic neurinoma, and reasonable certainty can indeed be attained by thorough differential diagnosis which includes examination of the protein content of the cerebro-spinal fluid. With an intracerebellar tumour the chances are about equal that it will be a benign astrocytoma or a malignant medulloblastoma, but there are many other, though less likely, possibilities: ependymoma, papilloma, metastatic tumour, dermoid cyst, and so forth. It will be useful, therefore, to consider broadly the relation to prognosis of the site of the tumour.

TABLE VII.—Regional Classification

	Total.	Living 7-9 years after operation.	Useful life.	Useful survival per- centage.
Frontal .. .. .	25	11	9	36
Central and paracentral ..	24	2	..	..
Temporal .. .. .	15	1	..	..
Parietal .. .. .	13	4	3	23
Occipital .. .. .	6	3	2	33
Pituitary .. .. .	30	19	10	33
Juxtapituitary .. .. .	7	3	2	28
Lateral ventricle .. .. .	1	1	..	..
Cerebellar .. .. .	23	10	9	39
Extracerebellar .. .. .	13	9	2	15
Total .. .. .	157	63	37	..

Percentage of the 135 who survived operation still leading useful lives = 27.4.

Percentage of the 157 patients treated still leading useful lives = 23.5.

Table VII. shows the results classified on a regional basis. Partly because a more rigid definition of the categories is impracticable, and partly because the number of cases included is small, the Table is not of great significance. The total number of tumours for each region is given in the first column, and in the second the number of patients who were still alive 7-9 years after operation. The central, paracentral, temporal, and, to a less extent, the parietal regions are clearly unfavourable regions, because it is in these that malignant gliomas and metastatic tumours abound; a conclusion contrary to that of earlier writers (Gowers<sup>12</sup>). Intracerebellar tumours are on the whole the most favourable tumours of all.

### RESULTS ACCORDING TO AGE

Table VIII. shows the results according to age. The number of cases is small, but as in Cushing's analysis<sup>5</sup> of over a thousand cases, the highest incidence of brain tumours is in the fourth and fifth decades. The percentage of survivors is greatest

in the third decade, and only slightly less in the second, fourth, fifth, sixth, and seventh decades. In the first decade the survival percentage is very low, but in view of the usual frequency of cerebellar astrocytoma in the first ten years of life it is quite likely that another series might show a very satisfactory survival percentage in this period. With the reservation that this is a very small number of cases, and perhaps to some extent selected, it may be concluded that, for intracranial tumours as a whole, age has no great bearing on prognosis until the eighth decade is reached.

If inquiry is made into the types of tumour in the survivors it is found that certain types preponderate among the survivors in different decades; glioma is the common tumour in the survivors of the second decade, pituitary adenoma in the fourth decade, meningioma in the fifth decade, and meningioma and acoustic tumour in the sixth decade. These differences depend mainly on the varying frequency of benign types of tumour at different ages. Among the 44 survivors who were over thirty years old when they came for treatment there is only 1 case of glioma.

The fact that a patient is over fifty, or even over sixty, when he comes for operation is evidently no bar to survival, and it is important to note that out of the 25 patients who presented themselves for treatment when they were already over fifty 12 were still alive when last heard from 7-9 years after operation. These comprised 5 meningiomas, 4 acoustic neurinomas, 2 pituitary adenomas, and 1 blood-vessel tumour.

### GENERAL SURVEY OF RESULTS

Table VII. shows the combined results as regards useful life. In the third column is given the number of survivors who were living a useful life when last heard from. This column has not been difficult to compile. It includes those free from all symptoms and those who are able to work though suffering from symptoms. Information on this point was reasonably accurate in all cases. There are 37 useful survivors from among the 157 patients operated on 7-9 years before. This gives a useful survival-rate of 23.5 per cent.; or, if we consider only the 135 patients who survived the dangers of operation, a useful survival-rate of 27.4 per cent. Thus, for patients with verified intracranial tumours undergoing operative treatment in the clinic in 1926-27 the chances of useful survival for a period of 7-9 years were roughly one in four.

Of the whole series of 157 cases, as can be seen from Table III., 14 per cent. died within a few weeks of operation; a further 12.7 per cent. after leaving hospital died in the first year; 12.1 per cent. died in the second year, while in the third year the percentage dropped to 5.1 and remained thereafter low. At the end of 7-9 years 40 per cent. were alive and 23.5 per cent. were living a useful life. There is some evidence that the incidence of benign tumour in this series is greater than would be found in a series of unselected tumours. This is elaborated in the full report on this inquiry.

These results are for the most part not so good as those obtained with tumours affecting other parts of the body. In a large series of histologically verified cases of carcinoma of the breast Lane-Clayton<sup>14</sup> found about 25 per cent. (206 out of 818) alive ten years after operation. For carcinoma of the cervix uteri the survival percentage ten years after abdominal hysterectomy was 36.6 (Lane-Clayton and McCullagh<sup>15</sup>). For three- or five-year periods the results of operation or radium treatment of carcinoma

TABLE VIII.—PROGNOSIS IN RELATION TO AGE  
*The Table is Based on the Age of Each Patient at the Time of his First Operation*

Age in years.	Total cases.	Dead.												Living 7-9 years.
		Post-op.	0-1	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9	9-10	10-14

Totals ..	157	22	20	19	8	3	9	4	1	2	2	2	2	63

of the lip, tongue, and rectum are still better. But for all these lesions there is always a preliminary sorting before surgical treatment is undertaken; the tumour can be felt and usually seen, and in certain cases examination will show that it is not radically operable. With intracranial tumours there is no easy way of rejecting the tumours that are unfavourable for radical treatment.

Intracranial tumours as a group are in some respects more favourable than the lesions mentioned above, since they include benign as well as malignant tumours. No true comparisons can be made, but from these considerations it is clear that the practical results of intracranial surgery to-day are not so very far behind those obtained in other fields of neoplastic surgery, notwithstanding its inherently greater difficulties and comparatively recent development. With development of technical and clinical knowledge and with more selection the late results for intracranial tumour are likely to improve still further, though it will always be necessary to bear in mind that the condition of patients at the end of a post-operative period of ten years or so is not the sole criterion of the value of operation. There will probably always be some use for palliative operations which can give temporary respite.

#### RESULTS COMPARED WITH OTHER SERIES OF INTRACRANIAL TUMOURS

Very little material is available for comparing the results of this series with those of other series. There is first the study of van Wageningen<sup>23</sup> in 1932 of the 149 cases treated in Dr. Cushing's clinic in 1924-25 (Table IX.). van Wageningen has estimated the survival and useful survival periods of his cases in average figures for each pathological group, and has not discussed the usefulness of all the survivors. Consequently it is not possible to tabulate his material for close comparison with the present series, but Table IX. gives some of his results and these may be compared with certain items in Tables III. and VII.

In van Wageningen's year the survival-rate 7-8 years after operation was 34.9 per cent. as compared with 40.1 per cent. of the present series. In his year there were more gliomas and fewer meningiomas than in 1926-27, but the balance was probably favourable to the year 1924-25, since there were 11 cerebellar astrocytomas as compared with 4 in 1926-27. Such an important difference in the incidence of one variety of tumour from year to year throws doubt on the significance of any conclusions that might be

drawn from comparing the results of the two years. The number of cases is too small. But the results on the whole are probably better in the 1926-27 group, though it may be noted that the useful survival of the acoustic neurinoma appears to have been much better in his series than in this one. In the two series the results in the malignant gliomas and metastatic tumours are, without exception, similar.

A more useful comparison can be made with the series of cases studied by H. M. Tooth at the National Hospital, Queen-square, between the years 1902 and 1911. Tooth's papers on this work<sup>20 21</sup> have probably not been given the attention they deserve. They are clearly documents of the first importance in the history of brain surgery, and at the time when they were published evidently constituted a valuable and sincere endeavour on the part of a neurologist to point the way for further improvements in surgical treatment of intracranial tumours.

Tooth analysed 500 cases of practically certain intracranial tumour which had come under observation at the National Hospital during the years 1902-11, and of these slightly less than half were histologically verified. His papers contain many valuable observations on different varieties of brain tumour.

TABLE IX.—*van Wageningen's Series, 1924-25*

Type.	Total.	Dead.	Untraced.	Living.
Glioma .. ..	80	68	..	12
Pituitary adenoma ..	26	3	1	22
Meningioma .. ..	16	8	..	8
Neurinoma .. ..	11	4	..	7
Craniopharyngioma ..	6	5	..	1
Blood-vessel tumour ..	4	3	..	1
Metastatic tumour ..	4	4	..	..
Miscellaneous .. ..	2	1	..	1
Total .. ..	149	96	1	52

Survival percentage = 34.9.

Table X. has been compiled from Tooth's material<sup>21</sup> for comparison with the present series. It comprises those tumours histologically verified by operation or necropsy in which the late result was known. The results are not strictly comparable with those of the present series for various reasons, but especially because it was not found possible by Tooth to subdivide the gliomas, and because the fate of the survivors was sometimes not known beyond a period of nine months. But comparison of the tables shows clearly that a tremendous reduction in post-operative mortality has been effected in the twenty-five years

TABLE X.—TOOTH'S SERIES, 1902-11

Type.	Total.	Dead.									Living.

Tooth<sup>11</sup> in 1913 reported 265 cases in which operation had been done for intracranial tumour between 1902 and 1911 inclusive. In 78 cases either the tumour was not verified or the condition of the patient on discharge from hospital was not known. In the remaining 187 cases the tumour was verified at operation or necropsy, and the late result of the operation was known in the cases of the survivors for periods varying between 9 months and 9½ years. The fate of these 187 patients is set out in the above Table. Pineal tumours and papillomas of the choroid plexuses have been included with gliomas. The remainder are placed in the pathological groups in which they were originally described, extracerebellar fibrogliomas and fibromas being grouped together. From study of the protocols it is probable that many cases classed as sarcoma would at present be regarded as gliomas.

The deaths after operation were classified by Tooth according as the patient lived hours, days, months, or years. In this Table all those dying within the first month have been grouped

together, as have all those dying between the second and twelfth months. This interferes with the chance of working out accurately the operative mortality, but in some cases that would have been impossible from the information available. Certainly the operative mortality was greater than 44 per cent. (83 deaths in 187 cases), for a number of the patients in the second column of the dead died in the hospital. Reference to the condition of the living is given in the text.

This method of dealing with the material takes no account of the unverified tumour cases and 32 such patients were living when last heard of. However, perusal of the protocols shows that most of them were in poor condition; only a possible 9 were able to do any work. In this present report the series of unverified intracranial tumours for 1926-27 has not been analysed or discussed because it does not provide information of any help in establishing the prognosis of tumours actually verified and pathologically classified.

that separate the two series, a reduction from over 50 per cent. to 14 per cent. and the survival-rate has greatly increased, from 16 to 40 per cent. The incidence in the operating theatre of benign tumours, such as pituitary tumours and to a less extent meningiomas, has considerably increased, and this fact favours the survival-rate of the later series. But this is balanced by the fact that the survivors of Tooth's series were incompletely traced; only 10 of the 31 survivors had been traced for as long a period as the survivors in the 1926-27 series. Of these, 4 were endotheliomas, 2 were cerebellar gliomas, 3 were cerebellar cysts, and 1 was an extracerebellar fibroma. Of the 31 survivors 14 were able to do some work at the time when they were last heard of.

Advances in surgical technique have doubtless played the major part in this improvement, but not a little must be attributed also to increased accuracy of diagnosis. Thus we find in Tooth's series that in 9 out of 44 verified frontal tumours exploration was made in the cerebellar region or over the wrong cerebral hemisphere. For the gliomas as a group exploration was in the right place in 76 cases and in the wrong place in 17 cases; while in the endotheliomas (meningiomas) exploration was in the right place in 29 cases and in the wrong place in only 4 cases. It is impossible not to admire the accuracy of diagnosis in meningiomas based as it can only have been on the most skilful interpretation of symptoms and signs, often of an inconspicuous or "false localising" character, and without the help of X rays, ventriculography, and other methods that have since proved so fruitful. In the year 1926-27 exploration was made in the wrong place in only 3 cases.

Sepsis also claimed a larger number of fatalities in Tooth's series than in the 1926-27 series, though it would give a false impression to imply that this complication of intracranial operations has been entirely eliminated.

Comparison of the two series shows that the outstanding improvement in the second lies in the immediate post-operative mortality which has, of

course, a considerable effect on the survival and useful survival-rate. It is not possible to measure the increase of longevity that may have resulted from other causes, such as more radical and effective treatment of the tumour.

The earliest literature on the results of surgical treatment of intracranial tumours affords no material for comparison with this series since it was, naturally enough, concerned almost exclusively with the immediate post-operative results; or, when late results were reported, the series of cases was too small to be of any statistical significance. It is fairly clear, however, that the number of useful survivors must have been very small. Thus in 1910 Byrom Bramwell<sup>2</sup> wrote, from a very wide experience, "In only two cases of intracranial tumour which have come under my notice in which an operation has been performed has complete cure resulted." Successes were expected by Starr<sup>19</sup> and by Gowers<sup>12</sup> chiefly in superficial tumours about the fissures of Rolando and Sylvius, tumours which are now found to comprise a rather unfavourable group, because in this situation such a high proportion of them are malignant; Starr and other writers of his time constantly refer to the high mortality of cerebellar explorations and to the inaccessibility of that region. The more recent observations of my series and of van Wagenen's series show that cerebellar tumours are on the whole by far the most likely to give lasting good results.

So much depends on accurate diagnosis and the safety of surgical access. It may well be found in ten years' time that the most favourable cases from the point of view of lasting useful survival are certain tumours of the third ventricle. Indeed, a growing number of observations already point in that direction.

CONCLUSION

It will be clear that I have been afforded the privilege of examining freely and critically the results of my former teacher, Dr. Harvey Cushing, and it is my earnest hope that I have done justice to this small section of what must be called his

epochal work. His cases have been accurately documented in pursuance of a far-sighted design, and the records are available in the Brain Tumour Registry at New Haven for such examinations as the future may indicate to be desirable. It is to be hoped that further inquiries of this nature may be made by others of Dr. Cushing's former assistants, so that before many years there will be added to the initial studies of van Wageningen and myself a greater and statistically more significant volume of knowledge on the late results of treatment of intracranial tumours. That such unrestricted studies of one man's work by his pupils are possible indicates to some extent the sense of partnership with which Dr. Cushing has invested his clinic, a quality that is the mark of all great teachers.

## CESTRIN TREATMENT OF CYSTIC DISEASE OF THE BREAST

By E. DAHL-IVERSEN, M.D.

PROFESSOR OF SURGERY IN THE UNIVERSITY OF COPENHAGEN

THE conservative management of cystic mastopathy finds a new basis in recent observations on the favourable influence of cestrin. Under this treatment the symptoms either disappear or are considerably relieved, and examination shows that the signs are diminished or almost absent, the results being especially good in early cases. The brownish or greenish discharge becomes serous and either decreases or stops. Cutler,<sup>1</sup> Gabrielianz,<sup>2</sup> and Taylor<sup>3</sup> have reported equally satisfactory experience of the cestrin treatment of mazoplasia and mastodynia.

During the year 1935 we have treated 22 cases of cystic mastopathy with cestrin and have obtained considerable recovery in 18. In 2 patients, both between twenty and thirty, the local and general condition was aggravated; and in 2 cases there was no effect. In older persons—i.e., in the middle forties—cestrin treatment will sometimes do harm, presumably because the patient, just before the menopause, is already suffering from a relative excess of cestrin; and the worsening of the general condition of the two patients under thirty resembled that usually observed in the middle forties, with flushes, sweating, anxiety, and especially dizziness.

In the light of our present experience we should advise a dosage of 2000–4000 mouse-units daily

<sup>1</sup> Cutler, M.: Jour. Amer. Med. Assoc., 1931, xcvi., 1201; 1932, xcix., 2152; 1933, ci., 1217. Ann. of Surg., 1931, xcii., 223. Surg., Gyn., and Obst., 1929, xlviii., 463. Amer. Jour. Obst. and Gyn., 1933, xxv., 504.

<sup>2</sup> Gabrielianz, A. G.: Amer. Jour. Obst. and Gyn., 1933, xxv., 499.

<sup>3</sup> Taylor, H. C., Jr.: Arch. of Surg., 1930, xxi., 42; Surg., Gyn., and Obst., 1933, lvii., 627.

by mouth or 10,000–20,000 m.u. once a week intragluteally. The course of treatment should last 3–6 months and in some cases should be continued longer, with pauses. The idea that the remedy is more than symptomatic is supported by the evidence of biopsy in the case described below. The treatment seems applicable especially to cystic mastopathy in young women, in the hope of avoiding operation. Surgery should be regarded as inadvisable unless cestrin proves of no avail or there is some doubtful change in the clinical picture. On the other hand, the conservative treatment necessitates close and continuous observation of the patient. The affected breast should be supported but on no account compressed.

We also try conservative treatment in older persons, but if it does not help we have less disinclination to operate, particularly if there is any suspicion of papillomata in the lactic ducts, or of early carcinoma. With older patients conservative treatment demands even closer and more continuous supervision. If operation is decided upon partial extirpation finds favour if the process is clinically localised; for experience shows that as a rule the condition does not recur, for many years at least. But partial operation likewise carries the necessity for careful observation. Where the changes are diffuse, partial extirpation is of course unwise and the best plan is ablatio mammae, with possible retention of skin, areola, and papilla. Whatever operation is adopted microscopical examination is essential, so that a radical removal may be performed if need be.

As an example of considerable recovery after cestrin treatment the following case may be quoted.

The patient was 49 and had had two children, the second being 15 years old. The menopause had taken place nearly eight years ago, menstruation having previously been normal. On and off for the past two years she had had stabbing pains in both breasts, and had been able to squeeze a dark, greenish, slimy liquid out of the papillae. Examination three months ago showed that the whole right breast was of firmer consistency than is normal, and full of numerous small lumps. A greenish, slimy liquid could be pressed out of the papillae from all quadrants. In the left breast there were corresponding changes in the two upper quadrants, and the process also extended a little way down into the two lower ones. The same sort of secretion as in the right breast could be pressed out of the papillae from the affected regions. Both breasts were slightly tender. The axillary glands were not swollen. Examination of the internal genital organs revealed no abnormalities.

After the patient had taken 86,000 m.u. of cestrin by mouth (3000 daily) there was considerable improvement. The stabbing pains were now less frequent and comparatively slight. The affected parts of the corpora mammae were softer and less tender, the small lumps were either not palpable, or only to be felt indistinctly in a few places. The discharge, which was now nearly serous, could be pressed out of only a few lactic ducts. In a limited region in the upper lateral quadrant of the left breast, however, the improvement was less pronounced than in the other parts, and in view of the patient's age a portion was excised under local anaesthesia. The histological picture was not characteristic, being suggestive of the regressive processes seen in a breast that has been subjected to energetic X ray treatment, or simply those observed at the menopause. There was a cellular reaction round the lactic ducts and this, in association with the characteristic pale epithelium and the presence of numerous glandular tubes without corresponding acini, speaks of regressive changes. The breast had evidently been the seat of abnormal development of the glandular tubes such as we see in benign cystic disease. There was no indication of malignancy.

We continued the cestrin, this time as a weekly dose of 20,000 m.u. intergluteally. After another 100,000 m.u.

had been given in this way we stopped the treatment and found both breasts soft, of almost normal consistency. The small lumps were no longer palpable. When the right breast was squeezed hard it was possible to press a little greenish discharge out of one of the lactic ducts, and from another one a little serous fluid. In the left breast a little serous liquid could be obtained from a single lactic duct, but only after firm pressure. The tenderness had disappeared. Eight months after ending the œstrin treatment the condition remains the same.

It will be observed that in this case of bilateral cystic mastopathia excellent results followed administration of œstrin (86,000 m.u. by mouth and 100,000 by injection). As already stated we are able to record a considerable degree of improvement in 18 of 22 cases in which œstrin has been used.

## THE EVIDENCE OF A BULLET WOUND SELF-DEFENCE OR MURDER?

By G. R. OSBORN, M.B. Melb.

FORMERLY MEDICAL OFFICER IN CHARGE OF THE COMMONWEALTH  
HEALTH LABORATORY AT KALGOORLIE, AUSTRALIA

THE deductions drawn from injuries caused by bullets may be of great importance in the law courts, and medical men who may have to give evidence about such injuries should be familiar with their characteristics. This was brought home to me by the following case.

### THE STORY

Z. is a Jugo-Slav employed as a miner on the Kalgoorlie goldfields; he is happily married and has three small sons. L. was a Montenegrin, also a miner, and the two men were formerly good friends. The friendship broke off when L.'s infatuation for Mrs. Z. became obvious, and he was warned to keep away from the house.

A few days before the shooting he sent a message to Mrs. Z. saying that he would go to see her at 9 p.m. on Monday (at a time when Z. would be at work in the mine). Mrs. Z. gave the message to her husband, who decided, he said, to give L. a bad fright. He borrowed a 0.44 Winchester rifle from his butcher, "to shoot a mad cat" and bought a few bullets from the local store. These bullets are made of lead without a hard jacket and carry a heavy charge of black powder; they are of the type used for shooting kangaroos. He took the rifle home and hid it under a bed in the front bedroom. He took no lawful steps to have L. restrained.

On the Monday afternoon Z. went to work as usual, but at 8 p.m. he pretended he was ill, was brought to the surface and went home. Reference to the plan of his house (Fig. 1) is necessary to follow the events which then took place. He found his wife sitting (at the place marked z<sup>1</sup>) sewing in the living-room by a long table. He told her not to worry and went into the front bedroom where his boys were sleeping. He then loaded the rifle and waited in the dark for the arrival of L. At the appointed time L. entered by the back door and walked up to the spot marked L beside Mrs. Z. He put his arms around her and started making love to her. When Z. heard this he rushed out of the bedroom to the spot z, and, holding the rifle with the butt under his elbow and the barrel pointing upwards, called out "Hands up, hands up!" L. was then shot dead. Z. did not move from the point z, and was still there when his brother-in-law returned with the police.

Z.'s story of the shooting was that when he called out to L. the latter lunged at him with his right hand while thrusting his left towards an inside coat pocket—a movement which Z. decided was to get a revolver. Actually the police found a fully loaded revolver in this pocket. Z. said that he then realised that if he did not shoot he would himself be killed, and

so he fired. He estimated that the distance from the muzzle of his rifle to L.'s head would be three or four feet. He said that L. fell straight backwards on to the floor, where he was found on his back with his feet towards Z. and that he did not move or utter a sound.

When the police arrived they found Z. standing at the point marked z; Mrs. Z. in the bedroom

quietening the three boys; and the body stretched out as described. Around the right side of the head there was a rather large pool of blood which was virtually part of a pool of blood and brain matter on the table (see Figure).

At a point marked B, near the kitchen door, was found a fragment of bullet, which had evidently had no velocity when it reached this spot, for there were no marks on the soft wall. The

FIG. 1.—Diagram of scene of shooting. z marks position of Z. when shooting L. z<sup>1</sup> shows position of Mrs. Z. and L. that of L. beside her. B shows where a fragment of the bullet was found, and A shows theoretical position if victim was shot from behind. The position of the body and blood stains on the table are indicated.

walls were of paper over hessian, and it would not be possible for the bullet to rebound from them.

### THE POST-MORTEM FINDINGS AND THE CONCLUSIONS DRAWN FROM THEM

On post-mortem examination a large gaping wound was found just behind external angle of the right eye, about 2 in. in diameter (Fig. 2). There was no bone in this hole and the brain substance, much macerated, could be seen through it. Behind this wound and immediately above the right ear was another hole, which was not ragged, but clean-cut; it admitted only the little finger and also communicated into the brain substance. No scorching or blackening was detected. On dissection the bones of the skull were found to be extensively fractured on the right side. The brain substance was also macerated very extensively on the right side and much of it was missing. In its substance were many fragments of small bone, and two pellets of lead were extracted.

From these findings the examiner drew the following conclusions:—

It is my opinion that the damage was caused primarily by a leaden bullet which had entered the head through a clean, well-defined hole above the right ear, smashing the bone there in radiating fractures, entering the brain substance, part of it remaining, and another portion escaping through the ragged tear in the soft tissues at the outer corner of the orbital cavity and that instantaneous death was the result.

This conclusion was presumably based on the belief, which is widely held, that bullets make a small wound on entry and a large one on exit. It gave

overwhelming support to the Crown's contention that Z. was lying and that he had shot L. from the back—in other words, that he was guilty of pre-meditated murder. The judge was quite emphatic that if the victim was shot from the front it could be self-defence—which was the plea advanced—but if he was shot from the back then the defence must fail and the jury could only bring in a verdict of wilful murder. The conclusion as to position drawn by the Crown medical witness accordingly became the central point of the trial. In fact there was virtually nothing else in dispute.

#### RECONSIDERATION OF THE EVIDENCE

Z. had been well known to me as a patient for over two years, and I had a high opinion of him. I was accordingly impressed by his absolute refusal to alter his account of the shooting. His lawyer told him that falsehoods would prejudice his case, and that the Crown was sure that L. was shot from the back; he suggested that perhaps L. had turned his head away as he fired. But Z. replied: "If I am to hang for it I cannot say anything else." We accordingly reinvestigated the evidence and I came to the conclusion that the Crown witness was wrong in supposing that the small wound is necessarily the one by which the bullet entered.

This idea, I found, is in fact based on the behaviour of hard (e.g., nickel-jacketed) rifle bullets of high velocity (over 2300 ft. per sec.) fired at a range of round about 200–800 yards, and it is not in the least applicable to soft lead bullets fired with a low muzzle velocity or at short range. Even the hard rifle bullet, at less than 200 yards, will probably cause a large ragged hole—(1) because of the terrific force of impact, virtually causing an explosion, and (2) because it is pointed, not truly cylindrical, and therefore "wobbles" in the early part of its flight, before being steadied by wind-resistance.

Hence, contrary to the general belief, a large entrance wound is the rule with rifle bullets fired at close range; and during the late war such wounds often gave rise to unfounded accusations that the enemy was using dum-dum bullets—i.e., bullets whose point has been removed in order that they shall flatten out instead of penetrating. (It is difficult to see that warfare is any less horrible when waged with nickel bullets.)

In the case before us, however, the bullets were of soft lead, unjacketed, and fired at very short range from a rifle with a muzzle velocity of about 1300 ft. per second. As soon as such bullets strike the body they "mushroom out," like dum-dums, and thereby cause great destruction of tissues. The result is that the entrance wound will probably be much bigger than the exit wound—if indeed there is an exit. If the soft bullet also has a wobble, which is likely if it is fired at close range, it is almost impossible for it to make a clean-cut entrance wound. This fact can readily be applied to the present case.

Referring once more to Fig. 2, the small clean-cut wound was at a point *g* over the right ear, and the large wound was 2 in. in diameter with its centre at *D*. *G-D* is approximately 2½ in.; for the first 1½ in. the skull is in place though extensively fractured, while the last inch has neither skull nor scalp. To cause a large circular hole the bullet must have struck the skull at, or slightly proximal to, the mid-point *D*, and approximately perpendicularly to the surface. If *g* is the entrance wound then *D* must have been struck from about the centre of the brain and emerged in the direction *D-J* which leads to a point *A* in the room (Fig. 1) where the bullet was not found. The absurdity of a course such as *G-K-D-J* is at once obvious,

for there is nothing in the brain to deflect a bullet. If the bullet entered the brain at *g* then the nearest it could possibly get to *D* would be about the centre of the forehead along a path such as *G-K-E*; much more probably it would have struck the skull again on the left side. Accordingly we can say it is impossible for *D* to have been struck from within the skull. There is however one other course which can be made out with *g* the entrance—i.e., *G-C-H*—which would leave the bullet nearer the back door but still a long way from *B* near the kitchen door. If the bullet did not at once enter the brain at *g* but tracked between the skull and scalp it would tend to take the course *G-C-H* which is ¾ in. away from *D* at its nearest point, and a course *G-C-D* is absurd.

By anatomical considerations we are forced to conclude that *g* cannot be the wound of entrance. This conclusion is strengthened by the fact that, though only one of three pieces of the bullet emerged from the head, the bone substance was driven into

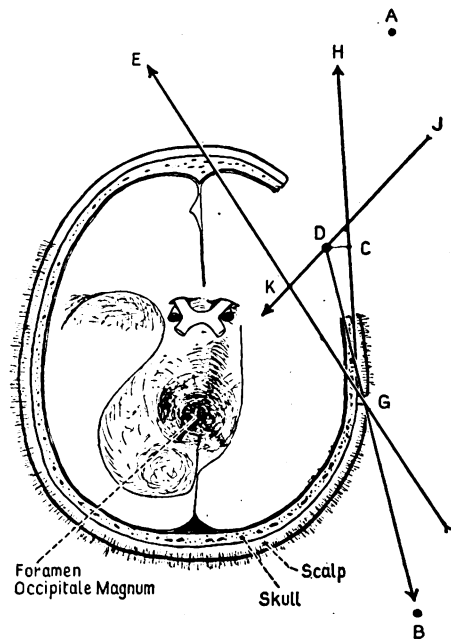

FIG. 2.—Diagram showing head injuries of the dead man and possible courses of the bullet. For explanation of letters, see text.

the brain and the loss of bone substance is from the anterior wound. A soft bullet has lost most of its energy when it mushrooms out, and a third of a spent bullet could not have caused the extensive injuries found anteriorly.

If on the other hand we examine the wounds as Z. said they were inflicted their anatomical explanation is simplicity itself.

If the bullet were fired in a direction such as *J-D* it would cause a large wound of entrance such as was found with its centre *D*. As soon as it hit the head it would mushroom out and burst into the three pieces in which it was found. Two of these three pieces continued on into the brain and were found there—i.e., their force was largely spent. The third piece of bullet was guided by the skull around between the scalp and bone in the direction *D-G*, in which plane it would not meet with any resistance until it reached the place where the skull and scalp turn medially towards the occiput. This place is, of course, over the ear, where the small round hole was found, and the course *J-D-G* leads directly to the point *B* near the kitchen door where the fragment of bullet was actually discovered.

No burning or powder marks were found around the wounds. The likelihood of such marks being present when the victim is shot from a short distance

depends primarily on the type of powder used. With cordite for example there is almost complete combustion in the firearm and no powder marks will be found, even at a distance of a few feet. With black powder, on the other hand, such as was used by Z., it is the rule to get powder marking at a considerable distance—e.g., 20 ft. or more. Hence in our case, with a range of only about 4 ft., if the small posterior wound was really the entrance a heavy black powder marking might certainly have been expected round it. If on the other hand the large anterior wound was the entrance the reason for its absence is obvious. At this short range the dispersion of the powder would be less than half the diameter of the part of the scalp and skull blown out, so that it must have been blown off also. Accordingly the evidence of the powder marking strongly supports Z.'s story.

We can also argue the position of the victim from the position of the body and blood stains on the table and floor.

Concussion is a hyperacute cerebral compression; it is manifested clinically by an instantaneous paralysis of the entire body and all its functions. Although people who are shot through the body may twist around in a great variety of ways before dropping down, those who have an injury which causes concussion always fall straight down limply. The injuries which L. received would cause instantaneous concussion and death, and he should fall as Z. said he did—straight back to where he was found without any movement at all. Had he fallen in this way it is clear that the right side of his head would have been towards the table as he fell, and the reactionary force would cause the blood and soft brain matter to fly out on to the table as the head fell past it, and then to form the pool on the floor to the right side of the head which was virtually part of the pool on the table. Had he been shot from behind the blood would have shot in the opposite direction—away from the table, and the body should have been on its face. The explanation offered was that the body fell on to the kitchen side of the table, lay there for a while and then rolled over to the position in which it was found. This is a most unlikely course, however, because the natural tendency would be to fall to the kitchen side of the table, and in any case it does not fit the facts nearly as readily as the simple description given by Z.

The jury returned a verdict of "not guilty" and Z. was discharged. The verdict was very popular, but it was clear that the life of the accused rested almost entirely on a medical argument.

EVIDENCE WHICH WAS OVERLOOKED

Details were submitted to Prof. Sydney Smith of Edinburgh for his criticism, and I wish to record my appreciation of his kindness in allowing me to quote the following passage from his letter:—

FIG. 3.—Beveling of skull in line of fire.

"There are one or two points which are of extreme importance which have not been described—namely, the examination of the wounds in the skull bone gave no indication about beveling. This is most important for it is almost invariable that the bone bevels in the direction of fire, and in the clean-cut

hole which was found posteriorly, beveling on either the inside or the outside was almost certain to be present, and if it were present, if it were on the outer table, it would indicate that the posterior wound was the outlet wound of the bullet; whereas if the beveling were on the inner table it would indicate that it was the entrance wound (Fig. 3). It would be more difficult perhaps to see whether there was

any beveling in the anterior wound, but if the fragments had been carefully collected and the skull reconstructed, it should have been possible to make this observation also.

"Secondly, no information is given about the amount of bone fragments that were found in the brain. The post-mortem report says in its substance were "many fragments of small bone pieces," and the question arises whether the number of fragments were more than could be accounted for by the loss of substance of bone in the posterior wound. If the number was greater, then they must have been driven into the skull from the anterior wound, for obviously if it were the exit wound, all bone fragments would be blown outside the skull.

"Thirdly, there is no evidence in the report to show where the fragments of bullet were found. This might also be helpful in fixing the line of fire."

SUMMARY

This is a case in which justice nearly miscarried through misinterpretation of post-mortem findings. It was wrongly supposed that bullets necessarily cause a small clean-cut wound at entry and a large irregular wound at exit. This is usually true of jacketed bullets fired from rifles with a high muzzle velocity (over 2100 ft. per second) at a range of 200-800 yards; but the same bullets encountered at shorter range, or soft bullets, or bullets fired from firearms with a lower muzzle velocity, may have the opposite effect, and the entry wound may be larger than the exit.

When black powder has been used powder marking may be expected up to a range of 20 ft. or more, and this may help to confirm anatomical deductions about the line of fire. Such deductions should be founded on very careful examination, bearing in mind the details of fundamental importance.

LEBANON HOSPITAL FOR MENTAL DISEASES, SYRIA. Sir Hubert Bond presided at the thirty-seventh annual meeting of this hospital held at Friends House on May 18th, and presented the report of the medical director, Dr. Stewart Miller. There had been a record number of 556 patients under treatment during the year, and the chairman commented on the surprising proportion of admissions (239) to the number of beds (370). As in England, the largest group of patients was of the schizophrenic reaction type (90 cases), the next largest being the more hopeful group with recurrent phases of excitement or depression (42 cases); 57 patients had been discharged during the year recovered, 69 improved, 18 not improved, 3 not insane. Of the 147 discharged, 75 had been there for less than three months, and all but 26 for under one year. The large proportion of early cases might be accounted for by the absence of certification in Syria. Dr. E. W. G. Masterman, chairman of the general committee, said that the work requiring doing at their own door was sufficient to warrant the erection of another hospital of equal size, if funds were forthcoming. They had decided: (1) to expand the hospital up to 500 beds; (2) to deal with borderland cases in a branch convalescent home in the Lebanon. A hundred new beds had been added during the last 18 months; there were now 12 houses, and the unit was considered a model for the country. Patients came for treatment from Egypt and other neighbouring countries. The director's position as lecturer at the University of Beirut on mental and nervous disorders brought him in touch with the fifth-year students who were the future practitioners of the Near East. The hospital stood in a key position there, and its influence as a healing centre amidst political strife was one of its brightest features. The new report will be sent on application to the secretary, Lebanon Hospital Committee, Drayton House, Gordon-street, London, W.C.1.

## MEDICAL SOCIETIES

ROYAL SOCIETY OF TROPICAL  
MEDICINE AND HYGIENE

A MEETING of this society was held on May 21st at Manson House, with Sir ARTHUR BAGSHAW, the president, in the chair. The subject for discussion was

**Intestinal Absorption in the Steatorrhœas**

Dr. N. HAMILTON FAIRLEY opened with a paper on tropical sprue, with special reference to intestinal absorption. The difficulty of presenting this subject had, he said, been considerably increased by the recent tendency in America and on the Continent to identify celiac disease, idiopathic steatorrhœa, and tropical sprue. While absence of intestinal lesions at autopsy and deranged intestinal absorption were common to the three diseases, the inclusion of tropical sprue was not justifiable. Idiopathic steatorrhœa included two groups: (1) adult celiac disease, cases of which presented bony deformity and a history of prolonged intestinal disturbance in childhood; (2) non-tropical sprue, which was a much rarer and more severe disease than tropical sprue, and often ended fatally despite modern treatment. Dr. Fairley's subsequent remarks concerned only tropical sprue. In this condition steatorrhœa was an outstanding feature and 80 per cent. of cases showed a total fat value exceeding 25 per cent. of the dried fœces (70 cases) on a single examination. With recovery the fœcal fat returned to normal limits. Over 50 g. of fat was not uncommonly excreted in 24 hours in severe cases when on a mixed diet. Hypocalcæmia was common and in 80 cases the average blood calcium equalled 8.8 mg. per 100 c.cm. In 11, it ranged from 5.1 to 7.0 mg. All had tetany. The blood phosphorus varied from 1.6 to 4.0 mg. per 100 c.cm. This finding precluded parathyroid deficiency as a basis of the hypocalcæmia. In 42 out of 50 cases flat glucose curves and curves showing a submaximal or a delayed maximal rise were demonstrated. Such findings had been attributed to the increased rate of removal of sugar from the blood due either to endocrine disturbance (Thaysen) or hypersensitivity to insulin resulting from compensatory excessive carbohydrate intake when fat was being poorly absorbed (Himsworth). Fairley and Bromfield had held defective absorption of glucose responsible. To test these views an intravenous glucose test had been devised. Of 10 cases of tropical sprue so investigated all showed high curves compared with the normal and a marked delay in the return to the fasting sugar level. Furthermore, on recovery, the intravenous glucose curves were always found to be lower and to approximate closely to the normal. This sluggish utilisation of sugar on intravenous injection was attributed to a decreased sensitivity to insulin resulting from defective absorption of glucose which was also the true explanation of the flat and delayed oral sugar curves. It followed that intravenous glucose and insulin were both indicated in gravely ill patients. Unabsorbed glucose underwent fermentation in the small intestine and gave rise to intestinal distension and the gaseous, acid features of the stools. Unabsorbed fat accounted for their greasy, bulky character. Calcium in the gut united with excess of fatty acids to form insoluble calcium soaps and this was probably the basis of the hypo-

calcæmia. Certainly the treatment of tetany by calcium per os was ineffective until the fat content of the stools had been adequately reduced by lowering the fat intake in the food.

Patients developing sprue sought medical advice for intestinal trouble, not for anæmia. Later in the primary attack and in relapses, anæmia was more constant and more severe, and when fully established it was megalocytic in type and indistinguishable from pernicious anæmia. The Price-Jones curves were similar and true megaloblastic hyperplasia of the bone-marrow occurred. Hyperchromia or orthochromia was the rule; if hypochromia were present complications should be sought. Microcytic anæmia in tropical sprue was invariably due to intercurrent disease. In 100 cases of sprue only 22 failed to secrete acid when histamine (0.25 mg.) was injected. After recovery it was found that the curve of acid secretion gradually returned to its normal level whatever that might have been. Similarly, clinical results indicated that the secretion of intrinsic factor was often only transiently deranged, for many cases of sprue resident in England remained perfectly fit in the absence of a maintenance dose of liver extract. In both these respects tropical sprue differed essentially from pernicious anæmia. Excellent results followed oral liver extract (1½ lb. whole liver daily) provided this treatment was combined with a series of graded high-protein, low-fat, low-carbohydrate diets. There was almost always a maximal reticulocyte response from the seventh to the tenth day and rapid regeneration of both erythrocytes and hæmoglobin. The adverse results reported by Castle and his colleagues (1935) with liver by mouth could only be attributed to the fact that appropriate dietetic measures had not been simultaneously instituted. The rapidity with which sprue patients responded to liver extract per os under these circumstances was comparable to that observed in pernicious anæmia and suggested that defective production of hæmopoietic principle rather than defective absorption caused the megalocytic anæmia. Iron absorption also was unexpectedly good; only occasionally did hæmoglobin production lag sufficiently behind the red cell output to render iron therapy necessary.

Provided appropriate dietary measures were instituted the relative efficacy of liver extract given orally or parenterally appeared to be essentially a question of dosage. In those rare cases where an inadequate hæmatological response followed administration of liver by mouth, parenteral injections were effective only in a correspondingly larger dosage. Clinical experience suggested that both oral and parenteral liver extracts might have effects over and above those explained by their content in anti-anæmic principle. Three crystalline substances had been isolated by Dakin and West. It did not follow, however, that any additional beneficial effects liver extract might possess depended necessarily on its content in a factor or factors absent from the diet of sprue patients. Obviously the pharmacological action of such constituents and their possible direct or indirect effect on the absorptive function of the intestine demanded consideration.

Castle and Rhoads and their co-workers last year attributed sprue in Porto Rico to a deficiency of extrinsic factor in the diet. In Dr. Fairley's series patients came from India, Malaya, China, Manila, and other parts of the world. At the time of develop-

ing sprue the vast majority were living on a diet which compared favourably in its protein content with that taken in Europe and included abundance of eggs and meat, besides vegetables and fruit. Many had been taking beef twice a day, fish once, and eggs and bacon for breakfast. They mainly comprised well-to-do people such as merchants, government officials, judges, bishops, lawyers, and army officers, and in general belonged to a class which did not develop avitaminosis. In Dr. Fairley's opinion the conception of sprue as a primary deficiency disease caused by lack of extrinsic factor or any known vitamin was quite untenable. The theory was not in accord with facts regarding the origin of sprue in parts of the world other than Porto Rico, nor with its absence in countries like Africa where dietary deficiencies were common. Finally it failed to explain the fundamental biochemical findings in regard to fat and sugar metabolism in this disease.

In summarising, Dr. Fairley elaborated his own view that the phenomena of tropical sprue could best be explained in terms of a metabolic breakdown of the gastro-intestinal tract characterised by defective absorption in the small intestine with or without defective secretion of Castle's intrinsic factor by the pyloric and Brunner's glands. Malabsorption generally affected both fat and glucose simultaneously. There were cases, however, where one or other was predominantly implicated; under these circumstances either steatorrhœa and hypocalcæmia or carbohydrate fermentation with decreased glucose tolerance dominated the picture. Avitaminosis, when it occurred, was a secondary phenomenon dependent on malabsorption or too restricted a diet self-imposed with the object of cure. In regard to causation, he pointed out that a somewhat similar intestinal breakdown occurred in hill diarrhœa under conditions of low barometric pressure and high humidity. In tropical sprue the factor and factors determining the breakdown had not been elucidated. The real enigma was geographical distribution, and whoever solved that problem would solve the ætiology of tropical sprue.

#### CELIAC DISEASE

Dr. C. WALLACE ROSS read a paper on intestinal absorption in cœliac disease, with remarks on the effect of liver extract upon carbohydrate metabolism. He began by summarising the recognised deficiencies of cœliac disease, including those relating to fat, protein, vitamins A, B, C, and D, calcium, phosphorus, iron, and Castle's anti-anæmic factor—the last being a great rarity. He then proceeded to examine the position in regard to carbohydrate absorption. Three explanations had been put forward for the flat oral glucose-tolerance curves found by workers in cœliac disease—namely, an endocrine disturbance (MacLean, Sullivan, Thaysen, and others), an excessive tolerance for glucose based on a high carbohydrate intake (Himsworth), and a simple absorptive deficiency (Marfan, Parsons, and others). The speaker presented a number of intravenous and oral glucose-tolerance curves and insulin depression curves showing (1) the association of high intravenous curves with flat oral ones; (2) the possibility of reducing these high intravenous curves towards normal by giving glucose intravenously over a period of time; and (3) the existence in cœliac disease of a state of relative insensitivity to insulin, comparable to that of a normal person on a low carbohydrate diet. These three findings were deemed good evidence of an absorptive deficiency for carbohydrates. A number of intravenous glucose-tolerance curves were then shown which had been derived from cases of cœliac

disease, chronic intestinal indigestion without steatorrhœa, abdominal tuberculosis, and cirrhosis of the liver, before and after treatment with Campolon or Anahæmin by injection, or liquid extract of liver by mouth. From these it was suggested that total liver extracts contain a factor, possibly identical with Himsworth's "insulin-kinase," which is capable of improving the glucose tolerance or the sensitivity to insulin where this is impaired by carbohydrate deprivation or by liver disease, sometimes to the great clinical benefit of the patient. This factor is not identical with Castle's "essential, anti-anæmia factor" and is not present to any great extent at least in anahæmin (Dakin and West's fraction). There was at present no evidence that this factor affects absorption.

#### DISCUSSION

Prof. L. G. PARSONS (Birmingham) said he saw no essential difference between cœliac disease in childhood and the idiopathic steatorrhœa of adults. There were, however, differences—especially in the blood picture—between cœliac disease and tropical sprue. Apart from occasional megalocytic anæmia and glossitis he failed to see any connexion between pernicious anæmia and cœliac disease either in the child or adult. Ross's observation that campolon intravenously improves the impaired glucose tolerance in cœliac disease, while anahæmin has almost no effect, appeared to be an insuperable objection to Castle's view that pernicious anæmia and cœliac disease are conditional deficiencies caused by lack of specific reaction between extrinsic and intrinsic factors. Whatever might be the cause of cœliac disease its symptoms par excellence were those of a deficiency disease; yet, as Fairley had shown in tropical sprue, this was not due to any known deficiency in the diet, but to malabsorption in the gut. It was a question of starvation in the land of plenty! Steatorrhœa was an erroneous term. Not only was there malabsorption of fat, but carbohydrate was involved as well. British pædiatricians had underrated the latter fact, but the work of Ross showed that glycorrhœa was as characteristic of cœliac disease as steatorrhœa.

Dr. H. P. HIMSWORTH said in view of the evidence now brought forward by Fairley and Ross he agreed that his own suggestion was wrong concerning the origin of the low glucose-tolerance curves in steatorrhœa. Glucose apparently was absorbed by an active process involving phosphorylation, lævulose by a process of simple diffusion. This might account for the different behaviour of the two sugars referred to by Prof. Parsons. Dr. Fairley had brought forward convincing evidence that calcium was inadequately absorbed. Johnson in America had recently shown that calcium gluconate in the gut prohibits the absorption of glucose; perhaps there was some connexion between the two. The effect of campolon in increasing the utilisation of glucose described by Ross was very interesting. He himself had tried to demonstrate this kinase action, but had failed.

Dr. JANET VAUGHAN agreed with Prof. Parsons that there were no essential differences between the cœliac disease of children and the idiopathic steatorrhœa of adults. She agreed there was evidence of malabsorption in idiopathic steatorrhœa and reviewed the biochemical results regarding fat, calcium, and glucose. In 9 out of 11 cases flat oral glucose curves had been found, but in contradistinction to the findings in tropical sprue the flat curves persisted after the clinical condition of the patient had enormously improved. Preliminary investigations

in conjunction with Dr. King indicated that there was a wide variation between the venous and arterial blood-sugar level when glucose was injected intravenously, and in this respect there appeared to be a difference in the utilisation of sugar in steatorrhœa patients and normal people. The blood picture was variable. The anæmia might be (1) hypochromic, responding to iron; (2) of megalocytic hypochromic type, responding to Marmite; or (3) erythroblastic (rarely). In cases responding to marmite the anæmia did not arise from lack of extrinsic factor as suggested by Castle.

Dr. REGINALD MILLER commented on the agreement of all speakers that malabsorption was the essential factor in cœliac disease. In his opinion defective absorption of fat was the essential defect and the carbohydrate disturbance secondary.

Dr. ROSS, in reply, said that in 6 cases which still had cœliac disease, but which had improved clinically, there was only slight improvement in the curves—less than he would have anticipated from their clinical progress. He thought Dr. Himsworth's idea regarding the absorption of lævulose a reasonable one.

Dr. FAIRLEY, in reply, said that demonstrable osteoporosis was rare in tropical sprue, though it probably did occur to some degree in chronic cases with persistent hypocalcæmia. In a certain number of selected cases at the Hospital for Tropical Diseases Dr. Mather Cordiner had failed to demonstrate it when people of similar age were used as controls. Obviously tropical sprue was altogether a milder breakdown than that of cœliac disease or of idiopathic steatorrhœa. With recovery both the oral and intravenous blood-sugar curves returned to normal; if they did not the patient had not recovered.

## ROYAL SOCIETY OF MEDICINE

### SECTION OF DERMATOLOGY

At a meeting of this section held on May 21st, with Dr. H. W. BARBER, the president, in the chair, a paper was read by Dr. S. LOMHOLT (Copenhagen) on

#### Alpha and Beta Rays in Skin Therapy

In such a city as London, he said, there were easy means of employing radium emanation, especially beta rays, in the practice of dermatology. During the last 40 years the importance of this treatment had been increasingly recognised in this speciality. Finsen's work on concentrated chemical rays was fundamental, and this method of treating lupus was still the best available. Treatment by X rays and radium had become even more important, but unless great and skilful care were exercised there was a real risk of producing burns, some of which remained incurable. Recent improvements in machines had rendered these burns less frequent however. Finsen's ultra-violet rays did not cause burns, as their potency was almost infinitely less than that of X rays or radium. The magnitude of the energy quantum varied inversely with the wave-length, the energy in the case of short waves being far greater than for long waves. Lord Rutherford had shown that the greater part of the mass of the atom was concentrated in a small nucleus of very high specific gravity. Though a cell might not be killed by irradiation it might suffer permanent damage, and so might lose its power of reproduction. The energy of the ultra-violet ray was comparatively small, but its effect on pathological cells was greater than on normal

cells. Alpha rays penetrated the skin to only a short distance, and hence were very suitable in the treatment of superficial skin lesions. It was an effective treatment for psoriasis on the body. Dr. Lomholt showed a number of plaques, charged with emanation, which could be divided up into pieces to fit the lesions to be treated; the amount of charge was regulated according to the particular requirement, with due allowance for loss of potency in the post.

Prof. E. RAMEL (Lausanne) read a paper on  
**Neuropathic Eczema**

He used the term neuropathic for the type of eczema in which the autonomic nervous system acted as a regulator mechanism on the allergic sensitivity of the skin. Recent investigations on the microbial flora of eczematous lesions had proved that the saprophytic microbes were able to produce sensitisation and an eczematous reaction of the skin. Dr. Ramel considered that this power of bacterial sensitisation of the skin was under the control of the autonomic nervous system, and that a certain type of eczema was met with which seemed to be of neuropathic nature, and which could be recognised by the appearance and development of the rash. This was a papulo-vesicular eczema, which at first was limited to one area, but soon showed a tendency to become generalised with a symmetrical distribution. After a period of oozing the eczema assumed the lichenoid form, and the confluent lesions became secondarily lichenified, thus closely resembling neurodermatitis. An important pigmentary change complicated the eczematous lesions, and on the more severe lesions vitiligo appeared. At the time of the appearance of the rash there was a complaint of definite symptoms—i.e., pruritus and intense burning sensations, to the accompaniment, in some cases, of insomnia, and the lack of response to the usual external treatment was a confirmation of the neuropathic character of the trouble. Tests, such as Platz's, showed the presence of a variable neuro-vegetative irritability, which was a subconscious result of the psychic shock. These patients often showed, also, great swelling of the lymphatic glands of groins and axillæ owing to the prolonged scratching. The blood always showed a high eosinophil count. Emaciation followed the injury to the trophic nerve centres; in some cases this went on even to cachexia. A knowledge of psychiatry was a great help in successful treatment.

## MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY

At a meeting of this society held on May 14th, Dr. EMANUEL MILLER read a paper on the

#### Limits of Psychopathology

These limits, he said, are defined by two conditions. First the mechanical limit or the limit imposed by heredity and by physical disorder, and (2) the idiosyncrasy of the nervous system. The reaction types can be regarded as in part dependent upon constitutional differences which determine the lines along which emotional development will take place. Whatever be the emotional patterns which develop the neurosis or the psychosis will be along fairly specific lines, although daily psychiatric experience is concerned with varieties and with "mixtures." Whatever be our theories the ultimate neurotic and psychotic forms will be, to this extent, predetermined and outside the range of psychotherapy. We can

hope, however, to restore to a patient his basic pattern by reducing the tensions which personal conflicts and frustrations in childhood and adolescence and maturity have produced.

With regard to the limits determined by the psychopathologies themselves, these are determined by the ideology of the theories, their fundamental assumptions. There is a tendency in most scientific disciplines to look for a unifying concept which shall explain the facts they have discovered. If it satisfies a large number of facts it more easily becomes a foundation-stone of doctrine, and the superstructure of theory takes on the shape predetermined by this foundation concept, sometimes where subsequent facts warrant alternative theories. The danger of these unitary ideas in psychological medicine is that the structure of the mind and the method of therapy are profoundly influenced. Adler has taken the idea of superiority and sees it permeating all human behaviour. That this is derived from the inferiority feeling is admitted. Both inferiority and superiority are complex mental states, and while the one may underlie the other, it is in Adlerian analyses not very fundamental. But Adler has nowhere made clear what this really means, whether it is gregariousness, whether it is or not an instinct or search for others and a satisfaction in their presence. We nowhere are told whether these are inborn dispositions or derivations. At most we can say they are all high level conative dispositions, and little if

any reference is made to the potency of unconscious processes.

The Freudian psychology has much more to recommend it inasmuch as it bases itself on an instinct psychology which lies at the root of psychogenesis. But here too the search for unitary principles has limited the structure of the mind by the narrow concept of a libido which makes a reductive analysis almost an infinite regress. It is freer, however, from limitations of more superficial psychopathologies in that it gives room for levels of conative activity—the it or instinctual level, the ego level and the level of ego—superstructures—morals, ideals, and sublimations. Psycho-analysis concerns all three levels simultaneously, but it limits the interpretation in lumping together erotic libido and ego libido in two mutually incompatible groups. Furthermore, despite recent developments in the psychology of aggression it does not take us beyond the pleasure principle. The death instinct is a piece of biological speculation and is an illegitimate attempt to escape from the impasse of hedonism to which psycho-analysis has become committed. That the load of sexual tension is greater than all other instincts is undeniable, but psychopathology is unduly limited and human nature unnaturally confined by the exclusion of other fundamental conative drives. For practical purposes as well as for theory a wider instinct theory is more illuminating, and what sheds most and widest light is calculated to produce the best therapy.

## REVIEWS AND NOTICES OF BOOKS

### Hydrotherapy and Climatotherapy

By MATTHEW B. RAY, D.S.O., M.D., M.R.C.P., Senior Physician, British Red Cross Clinic for Rheumatism, Peto-place, N.W. With a Foreword by Lord HORDER. London: Edward Arnold and Co. 1936. Pp. 312. 12s. 6d.

THIS book is divided into two sections of which the first contains an admirable introduction to the principles of hydrotherapy and notes on its practical application. Various systemic disorders are also discussed—those of the circulatory, respiratory, and genito-urinary systems, disorders of the skin and of the nervous system, and finally the rheumatic diseases. The author has classified and described the spas "in accordance with their main therapeutic indications" as regards the above disorders. This method of grouping the spas will not meet with general approval, for many hold that a first-class spa should be looked upon as essentially a repairing dépôt for disorders of metabolism. Any suggestion that this or that spa is only suitable for this or that disorder is to be deprecated, in so far as it may bolster up ill-equipped spas at the expense of those more deserving of support. Incidentally Harrogate and Bath are scarcely mentioned in connexion with the rheumatic diseases; yet both these spas have long had large voluntary hospitals where hundreds of cases of chronic rheumatic disorders are admitted and treated with a good measure of success every year.

The second section of the book deals with climatotherapy, and here the elementary principles are well set out considering our imperfect knowledge of what part the climatic factor plays in maintaining or promoting health. The short extracts about the health resorts require revision in certain respects. For example, for elderly invalids Weston-super-Mare is recommended in autumn and winter, but not in spring. Anyone who has experienced the cold autumnal and winter winds would discourage

elderly invalids from residing there during such months, whereas no place could be more delightful than Weston-super-Mare in April or May. The information supplied on foreign spas and health resorts is rather cursory, but there is much in the book which will stimulate the interest of practitioners in this country.

### Electrical Engineering in Radiology

By L. G. H. SARFIELD, M.Sc., M.I.E.E., A.Inst.P., Research Department, Woolwich. London: Chapman and Hall Ltd. 1936. Pp. 284. 25s.

THE developments of post-war years have wrought many changes in the design of X ray equipment, and the simple laboratory hook-up of former times has now been displaced by a comparatively much more complex if more efficient high-tension equipment. A certain amount of electrical knowledge is necessary for anyone who wants to understand every part of this technical work, but of this volume the greater portion is devoted to descriptive matter—notably historical surveys, results of experimental work and development, electrical characteristics, and constructional details, which are all clearly outlined. Mr. Sarsfield points out that recognised engineering standards are now being applied as far as possible to the manufacture of X ray equipment, while at the same time the peculiar requirements of the work to be done by this type of apparatus permit of the application of new standards. Such matters as the choice of suitable materials for the various duties, dielectric stresses, and methods of assembly are dealt with, specimen design sheets being included.

The realm of purely operative technique is avoided but many important hints are given on the best electrical conditions for service; the characteristics of the various components of an X ray set are outlined, and questions of lay-out are discussed. Valve filament operating conditions, the measurement of

essential electrical factors, tests, and the advantages and disadvantages of different methods of rectification all receive attention. In dealing with sphere gap measurements it is pointed out that misleading results may follow breakdown of the gap due to the presence of peaks superimposed upon the fundamental voltage wave applied to the X ray tube. This no doubt accounts for the discrepancies often apparent between the exciting tension as indicated by radiographic results and that indicated by the sphere gap measurement, especially where mechanical rectification is concerned. In this connexion the necessity for knowledge of wave shape is stressed, and, generally speaking, if Mr. Sarsfield's plea for accuracy of measurement is observed, much lower film bills will follow. High-tension systems, high-voltage cables, and the importance of proper earthing are also considered.

Little space is given to the purely physical aspect of X ray tubes, but the various types are well described. Various circuit arrangements, methods of control, maintenance, faults in apparatus, and the vexed question of signals are outlined, while protective measures, electrical safety, and radiation output efficiencies are discussed at some length. A chapter is devoted to describing special equipments for diverse applications in radiology, and such subjects as dark room lighting, heating of developing solutions, protective measures are not ignored. Examination apparatus for medical work does not form part of the subject matter, the author devoting the whole of his attention to the apparatus between the main supply and the X ray tube. Radiologists, X ray students, technicians, and others will welcome this treatise on a highly specialised subject. The book is well illustrated.

### The Variation of Animals in Nature

By G. C. ROBSON, M.A., Deputy Keeper of Zoology, British Museum (Natural History); and O. W. RICHARDS, M.A., D.Sc., Lecturer in Entomology, Imperial College of Science and Technology. London: Longmans, Green and Co. 1936. Pp. 425. 21s.

It is not generally realised to what extent modern theories of the causes of evolution are based upon selected evidence and upon the prejudices of the theorist. The fact that at least three fundamentally different theories are in currency at present makes us welcome this unbiased survey of the main facts and conclusions therefrom which have been used in support of these theories. The authors have covered a wide field and have subjected their material to the most searching criticism. Most biologists have assumed either that natural selection (to which 135 pages are devoted) is the main driving force of evolution, or that it is at least a necessary factor in the process, and elaborate mathematical theories have been erected on this basis. It will therefore come as a surprise to many that there is hardly any direct evidence for either of these assumptions, though in connexion with certain phenomena such as mimicry the circumstantial evidence is very strong. The origin and distribution of variations, the effects of isolation, and the concept of "adaptation" are here discussed very fully, and a chapter is given to an examination of the main theories of evolution other than the selection theory. The authors are in the end almost embarrassingly non-committal. They say truly that "any attempt to form an unprejudiced conclusion [as to the causes of evolution] labours under technical difficulties which frustrate it and limit it to a summing of possibilities," but it is difficult to

discover to which of these possibilities they consider the present evidence to point. They seem to favour the theory that the variations which have been mainly significant in evolution are of the nature of the mutations of the geneticist, though admitting that it is by no means certain that the environment may not have played a direct part in inducing changes under certain conditions. They do not consider the evidence sufficient to warrant the conclusion that selection has been an all-important factor in the spread of variations. And in this they are at one with the trend of discussion at the Royal Society summarised in a recent leading article (p. 1189).

There can be no doubt that a restraining influence of the kind here attempted is badly needed. Theories are being erected and even accepted as truth which are based upon unproven assumptions and upon experimental evidence of doubtful application to conditions in nature. On the other hand, it is unlikely that such sober argument will prove inspiring to readers. It must be admitted that well-directed flights of the imagination, provided there is a readiness to return to earth at a moment's notice, are the life blood of scientific progress.

### Youth, Sex and Life

By GLADYS M. COX, M.B., B.S. Lond. London: C. Arthur Pearson Ltd. Pp. 229. 3s. 6d.

To write a book on sex for young people and also for their parents is a difficult task. Dr. Cox has accomplished it with conspicuous success. "Of all the obstacles that stand in the way of human progress and happiness," she writes, "I believe that ignorance, prejudice and intolerance are the most potent, and that selfishness and deliberate cruelty are, more often than not, the products of these three." The book does not purport solely, as do so many that have recently appeared, to give to the young instruction on sexual physiology; it has the broader aim of providing information and guidance upon all the activities in which boys and girls are involved. The chapters deal with the following topics: physical fitness; physiology and health; how the mind works; drugs and gambling; exercise for health and pleasure, and sun-bathing; reproduction in man; adjustment to society; some thoughts on preparation for marriage; and sex problems. They are all written clearly and simply, without those pseudo-religious invocations which modern parents are apt to find slightly nauseating. Dr. Cox does not hesitate to give the reader advice; in fact the book is full of it. But the advice is so balanced and restrained, and couched in such simple and friendly language, that few adolescents could escape being favourably influenced by it. Difficult subjects are deftly handled. Psychology is not an easy subject to teach in such a way as to be intelligible and useful; human reproduction, which in this book is made to fit naturally into a wider context, is notoriously hard to explain to young people without irrelevant circumlocutions. Yet both these topics are dealt with with grace and judgment. Many parents are a little nervous of preaching to their children; and many have inhibitions which deter them from speaking openly about subjects on which they feel that children should be informed. This book should do much to remove these inhibitions. Practitioners are often asked to deal with adolescents passing through difficult phases. They could hardly do better than to introduce this volume to the parents with the suggestion that if it is found acceptable it should be handed on to their young.

## THE CHEMOTHERAPY OF STREPTOCOCCAL INFECTIONS

THE history of attempted chemotherapy in bacterial infections is so discouraging that any indisputable success in this direction is almost totally unexpected. It has seemed, hitherto that some radical difference between protozoal and bacterial infections offers an insuperable bar to the treatment of the latter by chemical means. Nothing in therapeutics is more certain than the disappearance of malaria parasites or trypanosomes under the influence of appropriate drugs; nothing has been more uncertain or perhaps more frankly disappointing than the effect on such a condition as streptococcal septicæmia of administering all manner of supposedly bactericidal compounds. It is true that many of these are demonstrably incapable of exerting any bactericidal effect in the dilution and under other conditions in which they find themselves within the body, but even were these conditions theoretically favourable in any particular instance, he would be an optimist who expected the old ideal of *therapia sterilisans magna* to take actual shape. In perhaps the only clear example of an interstitial or generalised bacterial infection which is susceptible to chemotherapy, the action of the drug is almost certainly indirect; this is the action of organic arsenical compounds in anthrax. It may well be true that apart from certain special situations, of which the skin and the urinary tract are examples, the bacteria of established infections are inaccessible to any direct bactericidal agent, either known or yet to be tried. Hence the startling nature of the success claimed for a drug, known best under the name of Prontosil, which made its début in Germany last year. This substance is one of a long series of dye compounds which had been synthesised in the hope of stumbling on something of therapeutic utility, and the original evidence in its favour consisted of experiments in which the development of streptococcal infections in mice was prevented by its administration, and of a number of rather uncritical but highly enthusiastic clinical reports of its effect in acute streptococcal infections in man. These reports and their confirmation on the experimental side by LEVADITI and VAISMAN have already been commented on in these columns.<sup>1</sup>

Now that English workers have fully satisfied themselves of the validity of these claims on the experimental side, and reached a significant if not conclusive stage in clinical trials, the importance of this discovery is brought nearer home. This development is marked by the appearance of two papers in our present issue. Dr. G. A. H. BUTTLE and his co-workers are not only in a position to confirm the original observations on the action of prontosil in mice, but they have studied a number of other new compounds, one of which, *p*-aminobenzenesulphonamide, has proved superior to prontosil itself. The significance of the animal experiments recorded in this and in the paper by Dr. LEONARD COLEBROOK and Dr. M. KENNY which precedes it may perhaps not immediately be grasped. It was shown repeatedly years ago that streptococcal infection in mice could be prevented if within an hour or two of infection the inoculated area were infiltrated with acriflavine or other substances of similar composition. At first sight these new experiments may appear to be of the same nature and of no greater significance, especially as they are sometimes referred to as protection experiments. The difference is that the action of acriflavine is directly bactericidal and purely local, whereas the action of prontosil, whatever it may be, is almost certainly not due to direct bactericidal action, and is obtained by introducing the drug, not locally, but either via the alimentary tract or by subcutaneous injection remote from the site of infection, which in these experiments is in fact the peritoneal cavity. Not only does this drug work, so to speak, at a distance, but it works when administered some days before, or at least some hours after, infection takes place; indeed it appears to have determined recovery in an animal already the subject of bacteræmia. This at any rate is something quite new; it is the first time that any drug has been shown to have a specific and regular effect on an acute bacterial infection when administered by the mouth. All observers are agreed that the effect is limited to infections due to *Streptococcus pyogenes*, although there are slight indications in Dr. BUTTLE's work that the meningococcus may also prove susceptible.

The conclusions drawn by Drs. COLEBROOK and KENNY on the basis of their clinical experience are commendably cautious. It is very much to be hoped that the therapeutic trial which they have initiated in this country will be extended and made to embrace types of acute streptococcal infection other than puerperal fever. It may well prove that others, mainly for anatomical reasons (since the type of streptococcus, within the *pyogenes* group, appears to be indifferent), react more favourably; erysipelas, for instance, is said by W. KRAMER<sup>2</sup> and others to respond remarkably to the treatment. The other side of the question with which this paper deals to some extent is the least satisfactory in the sense that almost nothing is known about it. How do these compounds act? They are only weakly bactericidal

<sup>1</sup> THE LANCET, Feb. 1st, 1936, p. 269.

<sup>2</sup> Münch. med. Woch., April 10th, 1936, p. 608.

in water, and not bactericidal at all and only bacteriostatic to a limited degree in serum; the serum of treated animals and patients supports the growth of streptococci, though to a somewhat diminished extent, and their virulence after contact with the drug in such fluids is unimpaired. LEVADITI and VAISMAN's facile and improbable idea that the drug acts by preventing capsule formation is unsupported in these experiments. Even in the whole blood of treated animals no bactericidal action was demonstrable. In fact no in-vitro mixture of bacteria, leucocytes, serum, and the drug itself can be made to do anything which will account for the therapeutic effects observed; clearly nothing short of the whole animal is a suitable field for the activity of this compound. Here therefore is a substance, identified as useful by the method of trial and error, the mode of action of which is wholly unknown. There is presumably a chemical side to the mechanism by which infection is overcome about which we know next to nothing, and on which it happens that this particular type of compound can exert an influence. This discovery, while obviously a therapeutic advance and possibly the prelude to others, is at the same time an indication that in this sphere of medicine we are only groping in darkness and finding something here and there, more by good fortune than by intelligent design. This is not to detract from the great achievements of pioneers in chemotherapy past and present; the symbols "205," "606," and "914" are a sufficient reminder of what they have attained. But these symbols are an indication also of the blind and laborious method by which alone such results can at present be achieved.

### MINERAL METABOLISM AND THE SUPRARENAL GLAND

THE growth of knowledge in some departments of medicine is painfully slow. Progress remains at a standstill sometimes for decades together, and, until lately at any rate, it has been difficult for the physician to reply to the layman who taunts him with the common cold or the measles epidemic. On the other hand, progress in some departments is so rapid that even the specialists are bewildered by the frequent reorientation of thought which the new discoveries necessitate. This is the case to-day with certain of the biochemical aspects of medicine, and is well illustrated by the fact that two arresting contributions have been made in the last few weeks to our knowledge of the rôle of the suprarenal gland in mineral metabolism.

One of these comes from investigations at the University of Virginia. SILVETTE and BRITTON,<sup>1</sup> whose work on suprarenal deficiency is already well known, have for some years attributed the fatal effects of suprarenalectomy to the disordered carbohydrate metabolism which ensues rather than to the fall of serum sodium and its attendant complications. In the common laboratory animals

these two effects generally go hand in hand, although a partial separation may be effected by administering salt in large quantities. SILVETTE and BRITTON, however, deliberately set out to enlarge the number of species on which suprarenalectomy had been performed in the hope of finding one in which the two effects might have been separated by Nature herself. This they have done, for they have found that in the opossum and marmot removal of the suprarenal leads to the usual disorder of carbohydrate metabolism and death in 6-8 days, but to a rise rather than a fall in the serum sodium. These results do not of course constitute a contradiction of the findings that suprarenal underactivity in dogs, cats, rats, and humans is associated with a sodium deficiency. This is a fact which has been well established by workers all over the world, as will be seen from Dr. McCANCE's Goulstonian lectures lately published in this journal. The theoretical significance however of SILVETTE and BRITTON's observations can hardly be over-emphasised, and it is to be hoped that the explanation of their findings may lead to a better understanding of the whole subject.

The other discovery, which has been made at the Mayo Clinic,<sup>2</sup> is not only of theoretical but also of considerable immediate clinical value. It has been known for some time that one of the signs of suprarenalectomy in the common laboratory animals and of Addison's disease in man is a rise in the serum potassium. The significance of this has not been understood, and the observations have not so far formed the basis of any therapeutic measures. It has now been found, however, that a crisis can be precipitated in suprarenalectomised dogs by the administration of potassium salts, and that a low-potassium diet greatly increases the animal's chances of survival after suprarenalectomy. Further, three patients with Addison's disease were made very much worse by an increased intake of potassium, and a diet low in potassium proved very beneficial. An unsatisfactory potassium-sodium ratio in the diet then may explain those disappointing and all too familiar cases in which the administration of salt has failed to maintain the patient's life. It is clear that, besides being given extra salt, patients with Addison's disease should now be placed on a low-potassium diet; but here a practical difficulty supervenes, for the planning and construction of such diets is not a matter which anyone can undertake. Fortunately the essential data are ready to hand, for potassium content has been determined in all the common American foods by SHERMAN, and the same service has been rendered for English foods by a group of workers at King's College Hospital. It should therefore be an easy matter for an experienced dietitian to give sufferers the necessary advice, and if the results live up to their early promise there is no doubt that directions for the preparation of low-potassium diets will soon be available for all.

## THE SURGERY OF BRAIN TUMOURS

WE publish this week the concluding part of a report on the late results of the surgical treatment of intracranial tumours. It constitutes the most thorough and critical analysis of a series of cases of brain tumour yet undertaken, and is a logical sequel to the same author's report to the Medical Research Council in 1929. Mr. CAIRNS has taken the identical cases he encountered when he was Dr. CUSHING's assistant in 1926-27, and has followed their after-history. While his facts were gathered during a visit to New Haven last year, his paper has been written, and his conclusions formed, since his return to England, and his judgment is the less influenced by local colour and argument. The result, it will be agreed, is a model of how the surgeon should evaluate his handiwork. As he says, the results are from the clinic of one "who has no peer in the art of neuro-surgery," and the organisation of Dr. CUSHING's unit can scarcely be overpraised. The M.R.C. report revealed one aspect of its efficiency, and the present paper bears witness to the success of its follow-up department. Of the cases which left hospital, "contact has been maintained with every one of these 135 patients." How many surgeons in this country could make a similar statement? There is surely no excuse for our general slackness in this direction. Money would be forthcoming for the inevitable expenses if we were sufficiently dogmatic about its necessity. Every hospital ultimately provides the operating paraphernalia its surgeons require, and such follow-up departments are as essential as special instruments. Lack of coöperation of patients is most often due to lack of contact between surgeon and patient. Frequently in hospital practice, the latter sees his surgeon only once—or even not at all—before and after operation, and there is no opportunity for more intimate discussion. The patient fails to realise that his need of the surgeon is not to be satisfied by the operation alone, but also by post-convalescent observation; and he remains unaware, on the other hand, that the surgeon depends on him for the amassing of experience. Now that the ranks of the profession are better filled, lack of time should no longer be a bar to the formation of this personal contact.

Comparable with the Registry of Bone Sarcomas, there has been set up at New Haven a Registry of Brain Tumours, consisting of full details of Dr. CUSHING's 2000 cases. As those will realise who have visited or worked in such a clinic—and similar ones are now firmly established in Britain—the amount of work entailed by such careful recording is enormous. But without it such an investigation as Mr. CAIRNS has made would be impossible. His observations will be found important, moreover, to general practitioners as well as to specialists, since they bring home clearly the need and value of early recognition of brain tumours. It is a tragedy that even nowadays, through unnecessary delay, blindness due to gross papilloedema or severe optic atrophy often follows otherwise successful operations for pituitary

tumours. And, if he does his part, what prognosis may the practitioner expect? This depends largely, of course, on the type of tumour, and some of the information Mr. CAIRNS provides will seem revolutionary to those unacquainted with the progress of this branch of surgery. The total operative mortality was 14 per cent., which is the mean between figures which vary from 5 per cent. to 30 per cent.; and be it noted, almost every case, however bad the "risk," was given the chance of surgical relief. Of the 135 survivors that left hospital, 63 were still alive at the time of the investigation, a remarkable proportion. Mr. CAIRNS probes much more deeply than this, and shows that 37 are still living useful lives. The bare survival figure would compare very favourably with the results of treatment of tumour elsewhere in the body, but he sees fit to make the comparison with the "useful life" survival-rate.

It is apparent that the glioma must no longer be considered as necessarily malignant: in fact emphasis is laid on the brilliant and permanent results which follow the removal of cerebellar astrocytomas in children. Surprisingly enough, these provide some of the best results of all. Against this must be weighed the fate of patients who have glioblastomas or medulloblastomas—tumours which constitute nearly half of all gliomas and are so persistently invasive as completely to resist surgical extirpation. Most surgeons, indeed, would refrain from operating on a glioblastoma if they could recognise it with certainty, but unluckily there are curable conditions that may closely mimic it. Has the future anything fresh to offer in the treatment of such growths? Radiation has provided means of temporary control, leading at times to remarkable recession of symptoms, and considering the advance of brain surgery during the past thirty years it is reasonable to hope for greater things to come, from one direction or another. For pituitary tumours the prognosis has lately been dealt with by Mr. CAIRNS in a contribution to our Prognosis Series (Dec. 7th and 14th, 1935) in which he said that since pituitary tumour destroys sight rather than life, the risks to life of operative treatment must be reduced to the lowest dimension. This is of course strictly true, but is only half the truth. In the present series, though there was only 1 operative death in 29 cases, as many as 9 more died during the subsequent years, either from evident tumour extension or intercurrent disease. This suggests that a more radical operation would have been justifiable on statistical grounds. Of the 19 survivors, 11 were at full work. The operation through the nose, responsible for these figures, has now been superseded by the transfrontal approach, and doubtless a similar inquiry into the late results of this procedure would prove more favourable, both as regards expectation of life and recovery of vision. Dr. CUSHING quotes figures by W. R. HENDERSON showing that during the decade 1921-31 42 per cent. of transfrontal and 37 per cent. of transphenoidal operations were followed by considerable visual recovery. Virtually complete restoration of vision followed 21 per

cent. of transfrontal operations but only 9 per cent. of transphenoidal. Nevertheless the older operation may still be the better in selected cases.

The question is often asked: Is the surgery of intracranial tumours based on sound economics? Are its results worthy of the enormous expenditure of energy involved? Strictly speaking the reply to such questions comes within the range of the politician; it is no part of the surgeon's duty to consider whether the cost of his apparatus would be better spent on cod-liver oil or battle-ships. But assuming that we are concerned less with economic organisation than with saving individual patients it becomes possible to reach a limited answer by stages. First, is it worth while, out of 157 cases suffering from a disease otherwise

inevitably lethal, to save the lives of 63? Most people would have no hesitation in answering "Yes," though the critical would rightly add, "if the life were worth living." Even they, however, could hardly avoid repeating "Yes" if told that 37 are useful members of society. Do such results justify the means? No one can measure the value of a life, but most of us believe it desirable that we should learn how they may be saved at whatever cost. The means adopted are the responsibility of the neurosurgeons themselves. Though they rest on a very different economic basis from other branches of surgery, and demand a disproportionately greater sacrifice from those interested, they appear to be fully justified by their achievement.

## ANNOTATIONS

### REPRISALS TO THE DOCTOR'S BILL

EXPERIENCED observers believe that allegations of professional negligence or want of skill are being increasingly employed as a weapon of defence against claims for medical fees. A vast amount of professional treatment is obtained on credit. No tariff or price-list is exhibited upon the surgery wall. Ancient tradition, fortified by judicial recognition, adjusts the charges to the patient's means. Accounts are probably not rendered until the crisis of the illness is over. It would therefore be not surprising if, when at last the bill is presented, the patient's gratitude for past services is less vividly fresh. The defaulting payer may be a husband or a father who is disappointed at the rate of recovery. He may be one who expects much for little or who looks upon the doctors as magicians who guarantee infallibility of diagnosis and certainty of cure. Accusations of negligence, unfortunately, have won a few glittering prizes in the law courts, supported by expert witnesses who will declare with retrospective confidence that some other treatment could or should have been tried. The last thing that an unpaid practitioner desires is worry over the collection of debts; he has other things to think of. If the prospect of allegations of negligence be added, he knows that even complete victory in the law courts will leave him worse off than before. Are these troubles so frequent under a system of cash payment or contract practice? If it be true that they are most often encountered where credit is given, how is the practitioner to mitigate them? The delay in asking for payment, the lump-sum bill, and the uncertainty of the scale of charges—these are elements which in part explain the occasional irritation of the person liable. Yet, after all, the remarkable feature of the situation is not so much the awkwardness of fee-collecting as the fact that default and recrimination are comparatively rare.

### COMPLETE CURE IN CARCINOMA OF THE COLON

IN view of the tendency of cancer to occur in the later years of life, survival without evidence of recurrence for twenty years seems justifiable grounds for reporting a "cure." C. F. Dixon and P. F. Olson are able to report 12 of these cases.<sup>1</sup> The time that elapsed since operation ranges from 20 to 24 years. Two of the patients died over 20 years after the

resection of the growth, the cause of death in one being unknown, and in the other amputation of an arm. Of the 12 patients 10 were alive at the time of inquiry. The age at operation varied from 30-64; in 9 patients it was 40-60 years. There is no question of the malignancy of the growths removed, for not only are the original pathological reports available, but the growths themselves have been preserved and in every case have been examined again to confirm the diagnosis. The authors normally grade sections of carcinomatous growths, according to certain criteria of malignancy, under four heads. They consider it very significant that in none of the 12 cases of 20 years' survival was the malignancy of the two highest grades. In 6 cases it was Grade I. and in 6 Grade II. It gives some idea of the prognosis of carcinoma of the colon if these figures are compared with the percentage frequencies of the four different grades in a series of cases. For 453 specimens of cancer of the colon, Dixon and Olson give the following figures: Grade I., 14 per cent.; Grade II., 61 per cent.; Grade III., 18 per cent.; and Grade IV., 7 per cent. They also found that the five-year survival-rates in these grades were 66, 54, 38, and 30 per cent. respectively. They feel that the relatively good chance of cure that can be offered to patients with certain types of carcinoma of the colon is a fact that should be recognised and made known.

### UNDULANT FEVER IN FRANCE

Dr. Justin Abet, who devotes his inaugural thesis<sup>1</sup> to this subject, states that the first cases of undulant fever to be reported in France were those published in 1908 by Danlos, Wurtz, and Tanon in the Paris district. In 1909 seven cases occurred at Marseilles and epidemics were reported at St. Martial (Gard) and St. Bauzile de Montmel (Hérault). From 1909 to 1912 numerous cases appeared in Languedoc, Provence, and Basses-Cevennes. The disease then came to a standstill and there appeared to be a progressive disappearance of the original foci. In 1920, however, undulant fever made its appearance in several places so that at the Hygiene Congress in 1925 Dubois and Lisbonne classified the affected departments into two groups—viz., (1) those which had been permanently affected, such as Corsica, Alpes-Maritimes, Var, Bouches-du-Rhône, Gard, Hérault, Aude, Pyrénées Orientales and the adjacent

<sup>1</sup> Surg., Gyn., and Obst., May, 1936, p. 874.

<sup>1</sup> Thèse de Paris, 1936, No. 236.

departments of Basses Alpes, Hautes Alpes, Vaucluse, Drôme, Ardèche, Lozère, and Aveyron; and (2) six departments with indigenous cases—viz., Haute Garonne, Hautes Pyrénées, Isère, Savoie, Doubs, and the Rhône. At first undulant fever in France was confined to the regions where abortion in sheep and goats was prevalent and was not found in those in which epizootic abortion in cattle occurred. After 1930 numerous cases of undulant fever of bovine origin began to make an appearance, cases being reported in Isère, Franche Comté, and Lorraine. In 1932 a ministerial order was issued making undulant fever notifiable and recommending examination of the blood in suspected cases in special laboratories. The recent increase in the number of cases is shown by the following figures. In 1933 408 cases were notified in 44 departments, in 1934 424 cases in 48 departments, and in 1935 427 cases in 53 departments. The notifications, it seems, considerably under-estimated the real incidence of the disease and are only really carried out, according to Dr. Abet, in departments possessing sanitary inspectors and in which practitioners, veterinary surgeons, and laboratories combine in tracking out the disease. The wide dissemination of undulant fever in France is an undoubted fact, but it is impossible to give even an approximate idea of the number of actual cases. In 1925 Lisbonne estimated the annual number of cases at 3 to 4000, but it is probable that this figure has been exceeded at the present time in view of the fact that many cases in country districts are overlooked or not reported.

#### DIFFERENTIAL CELL COUNTS OF PITUITARY GLAND

It is satisfactory to find that differential cell counts of the pituitary gland, originally devised by Rasmussen, are being made by research workers despite the extremely tedious nature of such work. It is only thus that the random claims of some endocrinologists, to the effect that specific alterations in the numerical proportions of the three types of cell in the anterior lobe characterise certain pathological conditions, can be verified or disproved. In a recent paper Dr. Frank Hawking<sup>1</sup> reports the results of differential counts of the anterior lobe of the pituitary in 12 cases of essential hypertension, 4 cases of nephritis, 6 cases of diabetes mellitus, 6 cases of hyperthyroidism, and 2 cases of Addison's disease. In 2 cases only of hypertension was the proportion of basophils greater than normal. Hawking cautiously concludes that this increase is not regular enough to be regarded as significant. This conclusion is of importance because it has been widely assumed, following Kraus and Berblinger, that an increase accompanies hypertension whether essential or secondary to nephritis, and this assumption has been a main plank in explaining the constancy of hypertension in Cushing's syndrome. An increase of basophils was found by Hawking in 1 case of diabetes, in 3 cases of hyperthyroidism, and in 1 case of nephritis. There is no confirmation of Kraus's statement that the acidophils are decreased in diabetes nor is there any evidence in hyperthyroidism of a correlation between the acidophil cells and hyperactivity of the thyroid gland. In 3 cases the percentage of basophils was high but the figure was within normal in 2 of these. It is difficult therefore to subscribe to the current view that the pituitary plays a dominant rôle in Graves's disease. In Addison's

<sup>1</sup> Jour. Path. and Bact., May, 1936, p. 689.

the clinical impressions of chancellors and prime ministers are apt to be as fallible as any physician's unless backed up by scientific knowledge. While it is improbable that many of his readers will follow Dr. Glover all the way, it should be impossible for any open-minded person, following the argument, to fail to pause and think, and to question some at least of the behaviour he has previously assumed to be rational and civilised. It is interesting that Dr. Glover considers that at present the greatest danger of being human is to give way to those periodic waves of smugness, affecting individuals and nations alike, in which self-satisfaction completely dulls any capacity for self-criticism or self-improvement.

#### MAN-MADE MALARIA IN INDIA

THE director of the Malaria Survey of India, Lieut.-Colonel J. A. Sinton, has found it necessary to point out, in properly vigorous language,<sup>1</sup> the great extent to which certain procedures, intended to increase prosperity and health in India, have in fact added to poverty, sickness, and death, merely because there has been disregard of their well-known effects in producing conditions favourable to the spread of malaria. Irrigation schemes form one of the most striking examples of this indictment. An engineering department makes its estimates for bringing water to agricultural land, but these are without proper provision for taking the water away when it has done its work. The result is a water-logged soil, whose fertility is thereby lessened, and a high water-table exposed in places as pools whose dangerous anopheles-breeding edges are probably quite disproportionate to the area the pools cover. Malaria follows, bringing not merely its own direct misery but its subsequent weakness, so that the victims can no longer get the best out of their already damaged land, nor the State its proper revenues from them. This sequence has been known in India for ninety years, yet man-made malaria is still being brought into being by it there. A main cause of this deplorable state of affairs was pointed out by Sir Herbert Emerson, Governor of the Punjab, at the opening of the Punjab Engineering Congress in 1935; it lies in the tendency of Government departments to look on matters only as they affect their own budgets, and not as they play a part in the prosperity of the whole Province; for the putting right of these grave defects is not merely expensive, but the cost, so far as the damage can be made good at all, is apt to fall on some other department. The remedy proposed is that work on no project of this sort should be begun until it has been considered by a committee representative of all interests concerned (engineering, agriculture, financial, public health, and any others), and unless all expense necessary to prevent harm has been included in the original estimate. But interdepartmental policies play but a small part in producing man-made malaria in India. The Malaria Commission of the League of Nations wrote in 1930 that attempts at malaria control had failed in that country, not merely through lack of coöperation but through religious objections not always sincere, and through irresponsible opposition in the press; while the Royal Commission on Labour in India wrote next year that action in health matters was too often limited to the toil of filing a written report. Though, then, there has been fault in the administration, now realised and in a fair way met, there has still to be faced by the

<sup>1</sup> Indian Med. Gaz., April, 1936, p. 181.

administration that opposition of vested interests, that stupidity, folly, pig-headedness, and even wickedness whose strength seems not to have been appreciably lessened in the past twelve years.<sup>2</sup>

### "DIE EWIGE MASKE"

FEW of us can resist a busman's holiday, especially when it promises a ride through familiar country. The Swiss film "The Eternal Mask," now running at the Academy Cinema, Oxford-street, London, W., shows first the professional dilemma of a young physician-pathologist, portrayed with great skill by Mr. M. Wieman, and later his reaction to the crisis he has precipitated. Convinced by animal experiment of the value of a serum he has produced against epidemic meningitis, Dr. Dumartin tries it on a dying man, in defiance of his chief's orders, with initial success. The patient, after rallying, dies of an embolism which, it is suggested rather surprisingly, could not possibly be due to the intravenous injection of the serum. Unfortunately the hero has been unwise enough to hint to the patient's wife that he is experimenting with a new remedy, and the most stirring episode in the film, from the medical point of view, is the demonstration of the swift consequences of this indiscretion. The widow turns on him, the local newspapers print abusive headlines, and the efforts of his chief to cover his action and to defend the reputation of the hospital are fruitless because Dr. Dumartin has disappeared. His wanderings about town, half-crazed by the tumult he has raised, his rescue from attempted suicide, and his painful return to sanity make a dramatic story. The contrast between the unsuccessful methods of handling the doctor's distemper and the wise psychotherapy which finally restores memory and balance is more likely to impress lay than medical members of the audience, but all will admire the effective use of film technique to suggest the mental adventures of a split personality. There is little to criticise in the vivid presentation of hospital life and ethics, though we ourselves have never met an institution so fortunate in attracting good-lookers to its medical and nursing staff.

### DUM-DUMS

THE dramatic excursion into detection which Dr. Osborn describes on p. 1295 has led him to make some useful comments on bullet wounds, and it is appropriate that these should appear at a time when the air is thick with accusations about the use and misuse of the so-called dum-dum bullet. On reviewing the evidence it will be found, we believe, that there is no good reason for regarding these as more horrible than other instruments of warfare. In the first place the definition of them is in practice exceedingly loose. We learn from the "Shorter Oxford Dictionary" that they are named after Dum Dum, a military station near Calcutta, and that the term refers to "a soft-nosed bullet which expands on impact." But the word "expand" is a little deceptive; for all that the soft-nosed bullet does is to break into smaller portions when it encounters hard tissues such as bone. It is here that it differs from jacketed bullets which, when fired at high velocity, have a considerable penetrating power; and the two types of bullet are designed to have different uses. The soft-nosed bullet is not intended to pass *through* the body; its whole force is utilised in inflicting a violent blow, and it has a correspondingly high stopping-power. Hence it is

used in hunting large or dangerous animals (e.g., rhinoceros or leopard), which are apt to take little immediate notice of a penetrating bullet; and for the same reason it has been employed by civilised nations in some of their colonial wars. The "dum-dum" bullet is now banned by the rules of war, but the line between legitimate and illegitimate is so slight that British prisoners came near to execution by the Germans in 1914 because they carried the regulation soft lead bullets for their service revolvers! The objection to the dum-dum seems in fact a little unrealistic. Lord Mottistone, in the House of Lords on May 12th, after speaking of them—perhaps truly enough—as more cruel than gas, went on to describe the kind of wound these projectiles make in animals. "There may be a very little hole in front," he said, "but I have frequently seen on the other side a hole as big as both palms." Since the object of the dum-dum is to avoid passage through the body, this type of wound must clearly be exceptional; but the real objection to Lord Mottistone's argument is that he said nothing about the havoc wrought by the standard jacketed bullet from the ordinary service rifle (to say nothing of the high explosive shell). The jacketed bullet fired at high velocity (over 2300 feet per second) can cause wounds as serious as any dum-dum, its exact effect depending mainly on the distance it traverses. At close range (under 200–300 yards) it travels with a slight wobble which usually leads to a large entry wound; at 300–800 yards it leaves the classical small entry and large exit wounds; at over 800 yards it is again likely to make a large jagged hole at entry. The regulation British service rifle bullet, with a velocity of 2400 feet per second, may thus reproduce the damage done by a dum-dum; but even if this is avoided the destruction of tissues along its track can be at least as disastrous. It may cause no wound "as big as both palms," but when fired at close ranges it may have a hidden cavitation action, producing a "tissue quake" with hæmorrhages an inch or more from the path of the bullet, which often means gross destruction. This particular effect of the penetrating hard bullet is obtainable only under appropriate conditions. To get the effect of the dum-dum, however, is ordinarily quite easy. There is no need to break international conventions by cutting the hard jacket off the bullet's point: all that is necessary is to use a rifle of high muzzle velocity at short range, or a firearm of low muzzle velocity with a soft lead bullet.

### RESEARCH DEFENCE SOCIETY

THE antagonists of medical research have been less pugnacious than usual during the past year, but the country is still being flooded with the propaganda of the financially well-supported antivivisection societies. Sir Leonard Rogers, as honorary treasurer of the Research Defence Society, has inquired into the finances of these societies and has discovered that since 1912, when the report of the Royal Commission appeared, condemning antivivisection methods, they have succeeded in collecting no less than £600,000 from the public. In its annual report the society's committee draws attention to the antivivisectionist shops that have become permanent features in certain localities. Some years ago in the House of Commons the Home Secretary said that he had no power to stop these displays: he thought then that the persons responsible could only damage their own cause by spreading the false belief that in this country cutting operations on animals were

<sup>2</sup> A leading article on the subject (quoted by Sinton) appeared in THE LANCET in 1924 (vol. i., p. 855).

allowed to be performed without anaesthetics. In the past year the Research Defence Society has been devoting increased attention to educating the public in the medical and scientific progress resulting from experiments carried out under the Act of 1876. Sir Leonard Rogers has been able to give many lectures to large audiences at universities and medical colleges, to local scientific and debating societies, and, on two occasions, to the boys of well-known public schools. The information given was valuable in helping the hearers to form a balanced opinion on the vivisection controversy. There has also been an increased demand for the society's leaflets, lantern slides, and general information from health authorities and numerous individuals, for use in local debates and lectures. Financially the society's position has slightly improved, thanks to a small legacy and to increasing subscriptions. Continued efforts are being made to obtain new members, in view of the enormous financial resources of the opponents of experiment.

### THE ROYAL SOCIETY CONVERSAZIONE

At the annual conversazioni of the Royal Society workers in different branches of science entertain one another with a wide range of exhibits and demonstrations. As a rule no contributions of purely medical interest are to be found: this is not to be regretted, since medical societies provide many occasions on which doctors show specimens, and the clinical investigator can always get entertainment and often help from seeing technical "tricks" from the repertoire of his colleagues in other sciences, and even if the more complex ones are beyond him enjoy those demonstrations that have a spectacular appeal. This year an exceptionally large number of guests assembled on May 28th. Practical hygiene provided two interesting collections of exhibits. That a brightly polished surface reflects heat well and absorbs it badly has been known for more than a century; the application of these facts to the protection of workers in the tropics or in the furnace rooms of industrial workshops has been shown to be practicable by covering the various materials used in the manufacture of sun-helmets, masks, gloves, and clothing with a layer of metal foil.<sup>1</sup> The use of similarly prepared materials in the construction of houses, factories, ambulances, and ships was illustrated by scale models. Other models showed the methods used in the attempted arrest of transmitted vibrations and noise for the exclusion of such everyday sounds as those of footsteps, electrical motors, and typewriters and for the elimination of traffic vibrations. Prof. H. H. Woollard's serial microphotographs of sensory endings in the human skin have been shown previously to medical audiences. In association with a new aesthesiometer for testing sensibility of the skin to touch and a new tachistoscope for experiments in visual perception and recognition they provided a remarkable group of exhibits. From the physicists came two attractive demonstrations: a collection of beautifully phosphorescent powders and an exhibition of the fluorescent effects excited by mercury vapour discharges in certain mineral salts. The estimation of oxygen in very small quantities of blood, the estimation of minute traces of carbon dioxide given off by living plants, and the micro-analysis of very small volumes of mixed gases provided examples of the greatly increased sensitivity and accuracy of chemical laboratory methods. Some common insects were used for three of the biological exhibits. It was

shown that the fine hairs of the anal cercus of a cockroach, clearly visible under the microscope, vibrated so rapidly on the approach of a bowed tuning-fork that they became invisible. The frequency of the responses set up by these hairs in their afferent nerves bears the same relation to the frequency of stimulation as does that set up in the mammalian auditory nerve by stimulation of the cochlea, so that it is possible, with a suitable stimulus, to obtain responses from tactile end-organs of a form that has hitherto been regarded as peculiar to the auditory apparatus. The blood-sucking bug rhodnius moults five times during development, passing through four newt and one adult stage. A very small gland in its head secretes both a moulting and an inhibitory hormone: the former, given to a first-stage newt, turns it immediately into a minute adult; the latter, given to a fourth-stage newt, causes it to turn into a giant nymph. The third biological contribution, one of more direct medical interest, is concerned with the study of the climatic factors influencing the multiplication of fleas. Mice, each sown with a numbered population of fleas, are kept separately for several weeks under standard conditions of humidity, warmth, and air supply. The conditions thus defined as inimical to the survival and to the propagation of fleas are expected to have important practical application in the control of flea-borne diseases such as plague.

### CHILDREN UNDER SCHOOL AGE

ON May 29th the Minister of Health addressed a circular (No. 1550) to local authorities charged with child welfare, expressing his anxiety about the attention given to the health of children between the ages of eighteen months and five years. In this transition period between infancy and school life, 16 per cent. of the children suffer from some disease or defect which is only discovered on entering school. The Minister recalls the intentions of the circular (B. of E. No. 1444), issued last January, about the provision of nursery schools and the admission of young children to infants' departments of elementary schools; he adds: "It is clear that whatever provision is made on the lines there suggested, very considerable numbers of children under the age of five will remain at home." It should, he states, be the duty of the health visitor to see these children at regular intervals; for, even in the few places where there are pre-school (sometimes called toddlers') clinics, their success must depend largely on regular visiting at home by the health visitor. The circular points out how desirable it is for the same authority (then, of course, the school medical service) to be concerned throughout with the health of the growing child, and where there is divided authority the Minister suggests ways in which the drawbacks could, and should, be removed; and finally he insists that no authority will get efficient work out of its health-visiting staff unless it pays them proper salaries. The circular ends with a R.S.V.P. to the addressee, to which we may hope the reply will be very prompt.

At a meeting of the court of Edinburgh University last week, intimation was made of a grant from the Rockefeller Foundation for research work in neurosurgery. The work will be carried out by a team of workers under the direction of Mr. Norman Dott, and the grant which totals £7500 will be applied to these studies during the five years from June 1st, 1936. A special ward will be provided for Mr. Dott's use at the Royal Infirmary.

<sup>1</sup> See THE LANCET, 1934, i., 37.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### CIII.—PROGNOSIS OF URINARY CALCULI

IN considering the prognosis of urinary calculi it is convenient first to view the urinary tract as a whole, and then to discuss in more detail calculi in kidney, ureter, bladder, prostate, and urethra. Urinary calculi, for all practical purposes, may be considered to originate in the kidney or bladder: they may be *primary*—i.e., occurring in an otherwise healthy urinary tract—or *secondary* to infection or obstruction. The common primary stones are composed of (1) uric acid, ammonium and sodium urate, or calcium oxalate, all of which occur in acid urine; or (2) calcium phosphate, or calcium carbonate, which occur in neutral or alkaline urine. Secondary stones, which are deposited in alkaline urine as a result of bacterial decomposition, are formed of calcium, ammonium and magnesium phosphate ("triple phosphate"), and calcium carbonate. The most common organism associated with stone is the *Staphylococcus albus*; in fact, when it is found in a urine, search should be made for stone. In considering the prognosis of each individual case various questions present themselves: what is the risk of leaving the stone alone, what are the chances of the patient passing it himself, what are the operation risks, and what the indications for operation; what should be regarded as contra-indications, and what can be done to prevent recurrences in the future? The answer to all these questions will be found in complete and systematic investigation of each case by X rays, pyelography (intravenous or ascending), cystoscopy, examination of the separated urines, bacteriology, and blood-urea estimate.

If a stone remains in the kidney it ultimately destroys the organ: the kidney undergoes fibrosis, and the pelvis and calices dilate, resulting in hydronephrosis. Sooner or later infection follows, and this in turn may result in pyonephrosis and perinephric abscess. A kidney with stone is also more likely to develop malignant disease than is a normal kidney. It has been estimated that 50 per cent. of unoperated cases of renal stone end with bilateral stones. A stone in the ureter usually produces incomplete obstruction, but eventually causes equally severe damage to the kidney. Should the obstruction become complete, anuria may result. A stone left in the bladder may produce obstruction and infection of the bladder and eventually pyelonephritis. A shadow shown in the kidney area by X rays should not be accepted as a kidney stone—especially on the right side where it may be a gall-stone—until it is proved to occupy the same position in the kidney in skiagrams taken during inspiration and expiration. A lateral X ray, moreover, will show a kidney stone to be lying on the bodies of the vertebrae: an intravenous pyelogram will settle any further doubt and give valuable information both as regards the position of the stone and the condition of the kidney. A stone fixed in one of the calices is less likely to pass naturally, but on the other hand it is doing a minimum of damage, and one can afford to wait: a uroselectan X ray will show whether it is held by a neck too narrow to allow its passage into the pelvis. When a calculus has passed out of the kidney into the ureter, it may be held up there, the commonest places of obstruction being the upper end, lower end, and, less often, the pelvic brim where the ureter crosses the iliac vessels. A stone which reaches the bladder generally passes

without difficulty, especially in women, but it may stick in the internal meatus or in the urethra.

#### KIDNEY STONES

Assuming an otherwise healthy subject, when the urine is uninfected and the stone of such a size that it can be removed through the renal pelvis, the operation risk is a small one, estimated at about 2 per cent.: whereas in cases of urinary infection, and a stone too large to allow removal through the pelvis, which necessitates cutting into the renal parenchyma, the risk may be as high as 20 per cent. From the foregoing considerations it is seen that most aseptic kidney stones are best removed, though exception may be made in the case of a fixed stone which is doing no damage and producing little in the way of symptoms or disability. It may be unnecessary also to remove multiple small stones from a patient who passes them from time to time. When the stones are bilateral, it is advisable to operate on the better kidney first; this gives the surgeon a free hand to deal with its fellow later on. Large bilateral stones are probably best left alone. The kidney function is already impaired, and removal of the stones involves cutting into the kidney tissue and producing further damage; there is also a risk of secondary hæmorrhage, which does not occur when the stone is removed through the pelvis.

The onset of infection is an indication for operation, since when infection is added to back pressure damage to the kidney progresses more rapidly. In most cases in which infection is secondary to stone, the infection clears when the stone has been removed.

*Secondary* stones come into a different category: it is doubtful how far removal of the stone will effect recovery of the kidney, and unless the infection is cured, the stone will recur. Provided the second kidney is healthy and uninfected, nephrectomy may be preferable to pyelolithotomy or nephrolithotomy; this is especially so when the infecting organism is the *Staphylococcus albus*. Patients with large branched bilateral calculi, plus infection, should be operated upon only if some urgent complication demands it. Much can be done for them by spa treatment.

#### URETERIC STONES

Eighty per cent. of the stones which pass the ureteropelvic junction eventually reach the bladder, without producing a complete persisting block or necessitating operation. Surgical intervention becomes necessary however if a complete kidney block persists: the onset of this is characterised by severe kidney pain, and may be accompanied by complete anuria. Other indications for operation are symptoms of infection and evidence of dilation of ureter and kidney, determined by intravenous pyelography. Once dilation begins behind the obstruction the chances of the stone passing naturally are diminished. Every case of ureteral stone should be X rayed every two months, and if the stone has not progressed downwards since the last X ray examination, intravenous pyelography should follow. The position of the stone should be confirmed shortly before operation, in every case that comes to operation.

#### BLADDER STONES

A stone lodged in the intravesical portion of the ureter gives rise to frequency and pain at the end

of micturition, symptoms which might lead to the conclusion that it had reached the bladder. An X ray may be deceptive, so that cystoscopy is advisable. The majority of bladder stones, however, that one has to legislate for, are relatively large and their most fertile causes are (1) obstruction and infection, (2) conditions which prevent proper emptying of the bladder—e.g., a diverticulum, and (3) diseases of the central nervous system. The ideal method of treating an uncomplicated bladder stone is to crush and evacuate it; in skilled hands this is a safe procedure, and entails only a few days in bed. Recurrence is due, not to leaving fragments behind (as can be proved by cystoscopy), but to continuation of the conditions which produced the stone. For example, a stone associated with prostatic obstruction is only an incident in the course of an enlarged prostate, and the correct procedure is prostatectomy. A stone associated with stricture may be crushed after internal urethrotomy. Stones formed round a foreign body are not suitable for litholapaxy; the latter is contra-indicated also with sacculated stones (dumb-bell-shaped stones, of which one part lies in a sacculus and the other projects into the bladder), and when a diverticulum is present, as this prevents proper evacuation of the fragments. Care is needed when litholapaxy is done on a patient whose bladder has been opened suprapubically on some former occasion, since it is easy to tear the bladder from the scar with the evacuator and thus to produce a perforation.

#### PROSTATIC STONES

Two kinds are described: (1) those arising in the gland itself, and (2) those whose origin is in kidney or bladder. The latter rank as urethral stones. The former are small dark yellow-brown stones, like grape seeds, composed of an albuminoid substance with lecithin: they are of little importance, but may increase in size from deposit of phosphates.

#### URETHRAL STONES

The most common sites for a stone to lodge are in the region of the triangular ligament, and at the fossa navicularis. A stone held in the former position can be pushed back, with a large bougie, into the bladder, where it can be crushed and evacuated; whereas in the latter situation it can be delivered by meatotomy. A stone lodged behind a stricture may necessitate urethrotomy. Large stones are found occasionally in the posterior urethra. I removed recently, by suprapubic operation, one that had resisted treatment by Christian Science for seven years.

#### Prophylaxis

We now have to consider what can be done to prevent recurrence of stone. We know little about its causation, but the main factors appear to be the deposit of crystals from the urine, and the presence of an "irreversible" colloid which acts as a scaffold round which the stone is built. Heredity, climate, food, and water-supply ("chalky" or hard water) all play their part, and deficiency of vitamin A may be a factor. Heredity is exemplified by the tendency to produce uric acid and the rarer cystin stones: in hot climates the concentration of the urine favours stone formation; and the influence of food is shown in India, where stone is common in the wheat-growing areas, but rare in the rice-growing ones. Crystals deposited in the urine may be of uric acid, calcium oxalate, or phosphates; and the

general principles to be adopted by those who pass crystals are to eat moderately, to attend to the bowels carefully, to take regular exercise, and to flush the urinary tract daily with appropriate mineral waters; this is done best before breakfast, when the stomach is empty. The recurrence of secondary stones may be prevented by relieving obstruction, treating the bacterial infection, and keeping the urine acid. Spa treatment from time to time is of great benefit with both primary and secondary stones.

The uric acid in the urine is partly endogenous, from the products of metabolism, and partly exogenous, from food nucleins. The indications, therefore, in patients passing uric acid crystals or stones are to eliminate foods rich in purins (liver, sweetbread, kidney meat extracts) and to flush the urinary tract with alkaline waters (Contrexeville, Evian, Vichy); so-called uric acid "solvents" are of doubtful benefit. The oxalates in the urine, normally kept in solution by the acid sodium phosphate, are also partly exogenous, derived from the oxalic acid and calcium of the food, and partly endogenous from protein metabolism. Insoluble calcium oxalate crystals are deposited in acid urine, especially after ingestion of substances with a high oxalate content. A vegetarian diet is more prone to produce oxaluria than a meat one. Oxalate stones are the least likely to recur, and though we have little control over endogenous oxalates much can be done to prevent recurrence by diet and moderation of alcohol. These patients should avoid strawberries, raspberries, pears, rhubarb, beetroot, asparagus, spinach, and tomatoes: they should abstain from excess of sweets, chocolates, and jams. Meat extracts and "insides" (liver, kidney, sweetbread) should be forbidden. The best alcoholic drink for them is dry cider, malic acid being a solvent of oxalates, but they are allowed in moderation claret, burgundy, dry sherry and dry champagne, old whisky, and gin. They should flush the urinary tract daily with alkaline minerals, as already indicated. Magnesium salts—e.g., Dinneford's magnesia—taken from time to time may be helpful.

In phosphaturia there is a diminution in the urine of the acid salts which keep the phosphate in solution, and when the urine becomes neutral or alkaline these are deposited. With certain bacterial infections the urine becomes alkaline and triple phosphates are deposited. Phosphaturia is apt to follow the ingestion of too much alkali; it occurs also with dyspepsia and with overwork, worry, and mental strain. In patients suffering from phosphaturia these conditions should be corrected, the urine should be rendered acid—by dilute mineral acids or acid sodium phosphate—and the vegetable food limited.

SYDNEY G. MACDONALD, F.R.C.S.,

Surgeon in charge Genito-urinary Department, West London Hospital; Genito-urinary Surgeon to Royal Masonic Hospital.

---

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—It is hoped that the nurses' home extension to this hospital will be finished this year, the main hospital block by October, 1938, and the administrative block by March, 1941. The cost of reconstruction has been estimated at about £400,000, of which £100,000 has been contributed. In the new hospital the total accommodation will be about 290 public cots, and 36 paying-patient cots; the buildings will be divided into units of 20 cots, each entirely self-contained. To reduce the risks of cross-infection, some of the wards will contain only one cot, and the largest number of cots in any one ward will be 6.

## SPECIAL ARTICLES

## THE POISONS RULES

WHAT EVERY PRACTITIONER SHOULD KNOW

POISONS law is an intricate subject and the practitioner who would try to master it should read Mr. Linstead's excellent book,<sup>1</sup> but, before doing so, let him be warned that he may require more leisure than he has a right to expect and a reserve of patience which should, more properly, have been exhausted in coping with the sick—and their relations. Nevertheless, whether they wish to go deeply into the subject or not, all practitioners must willy-nilly familiarise themselves with certain points in the new poisons rules which came into force on May 1st last.

Two general rules applicable to all poisons should be borne in mind. The first deals with the storage of poisons in the surgery or dispensary. Henceforward the doctor must see that all his containers are impervious to the poisons they contain and that they are stout enough to prevent leakage. Secondly, when he supplies an embrocation, liniment, lotion, liquid antiseptic, or any other substance for external application, he must ensure that the container in which it is supplied is labelled so as to show not only the nature of the article—e.g., "The Lotion," "The Liniment," &c.—but also the words "For external use only."

The new rules comprise 12 schedules. Mercifully for him, the practitioner need concern himself with only two of these—namely, the first and fourth—the remaining 10 schedules being matters for the pharmacist. Appended is a list of the poisons in the First and Fourth Schedules, and we think that the practitioner would be well advised to cut it out and hang it conspicuously in his surgery so that he, and his dispenser if he has one, can readily refer to it. The First Schedule consists of a large number of substances to which special restrictions apply. For the purposes of his profession, a doctor may buy poisons from any "authorised seller of poisons"—i.e., a chemist or a wholesale or manufacturing firm—but, under the new rules, these substances in the First Schedule can only be supplied by a seller to a doctor on receipt of a written order signed by the doctor. It is true that, in an emergency, the doctor can get a supply of any substance in this schedule either by going in person to the chemist and signing the poisons register or, alternatively, by promising to send the written order, duly signed, to the chemist within 24 hours of receiving the substance; but, should he forget or otherwise fail to supply the written order, he becomes liable under the Dangerous Drugs Act to a penalty which may take the form of a fine or even imprisonment—not, we are relieved to find, of banishment or execution. Again, when dispensing a medicine containing a substance in the First Schedule, the practitioner is now required to label the bottle with his own name and address, to enter the date of supply of the medicine in his day-book, and also the ingredients of the medicine, the quantity, and, finally, the name of the person to whom the medicine was supplied.

So much for the rules about poisons in the First Schedule in so far as they affect practitioners. By referring to the list at the end of this article it will be seen that the Fourth Schedule consists of some of the drugs in the First Schedule in respect of which

the restrictions are even more exacting. Under the new rules, a doctor's prescription is necessary before any substance in this group or any preparation containing one of them can be sold retail, and this applies to all proprietary preparations, sold under trade names, which contain any of these substances. Not only must the prescription be signed by a doctor and dated in his own hand. It must also have his address on it (unless it is a N.H.I. or local authority prescription), the patient's name and address, the total amount of medicine and the dose. Further, unless the doctor specifies how many times or at what intervals the prescription is to be repeated, it can only be dispensed once and, unless the prescription is made out accurately according to the rules, it cannot be dispensed at all.

It is not easy to foresee as yet all the end-results of these new restrictions but one obvious and salutary effect of them will be the disappearance of these poisons, notably amidopyrine, from patent medicines, which should help to check the deplorable habit of indiscriminate symptomatic self-treatment so freely indulged in by the public. This, in itself, should help to console practitioners for the extra trouble involved. It was not to be supposed that the new rules would work smoothly from the beginning without a hitch of any kind. Most of the difficulties which have so far cropped up have been primarily matters of concern to pharmacists rather than to doctors, but one or two points of interest to both may be mentioned. For example, into what category fall such things as mouth-washes, eye-drops, ear-drops, and douches? Are they to be regarded as medicines for internal or external application? The ruling here seems to be that they should be dispensed in "poison" bottles but need not be labelled "For external use only." The Pharmaceutical Society has also asked the Home Office for a ruling, which has not yet been promulgated, on the question as to how many times a chemist may repeat a barbiturate prescription marked "To be repeated." Pending the Home Office decision, we would point out that, according to the letter of the rules, such a prescription is inaccurate and therefore should not be dispensed at all.

## FIRST SCHEDULE

*Substances falling within the Poisons List to which special restrictions apply*

Alkaloids, the following; their salts, simple or complex:

- Acetyldihydrocodeinone.
- Aconite, alkaloids of, except substances containing less than 0.02 per cent. of the alkaloids of aconite.
- Apomorphine except substances containing less than 0.2 per cent. of apomorphine.
- Atropine except substances containing less than 0.15 per cent. of atropine.
- Belladonna, alkaloids of, except substances containing less than 0.15 per cent. of the alkaloids of belladonna calculated as hyoscyamine.
- Benzoylmorphine.
- Benzylmorphine.
- Brucine except substances containing less than 0.2 per cent. of brucine.
- Calabar bean, alkaloids of.
- Coca, alkaloids of, except substances containing less than 0.1 per cent. of the alkaloids of coca.
- Cocaine except substances containing less than 0.1 per cent. of cocaine.
- Codeine except substances containing less than 1 per cent. of codeine.
- Colchicine except substances containing less than 0.5 per cent. of colchicine.
- Coniine except substances containing less than 0.1 per cent. of coniine.

<sup>1</sup> Poisons Law. By Hugh N. Linstead, secretary of the Pharmaceutical Society of Great Britain. Reviewed in a leading article in THE LANCET of May 16th (p. 1121).

- Cotarnine except substances containing less than 0·2 per cent. of cotarnine.
- Curarine.
- Diacetylmorphine.
- Dihydrocodeinone.
- Dihydrohydroxycodone.
- Dihydromorphine.
- Dihydromorphinone.
- Egonine except substances containing less than 0·1 per cent. of egonine.
- Emetine except substances containing less than 1 per cent. of emetine.
- Ergot, alkaloids of.
- Ethylmorphine except substances containing less than 0·2 per cent. of ethylmorphine.
- Gelsemium, alkaloids of, except substances containing less than 0·1 per cent. of the alkaloids of gelsemium.
- Homatropine except substances containing less than 0·15 per cent. of homatropine.
- Hyoscine except substances containing less than 0·15 per cent. of hyoscine.
- Hyoscyamine except substances containing less than 0·15 per cent. of hyoscyamine.
- Jaborandi, alkaloids of, except substances containing less than 0·5 per cent. of the alkaloids of jaborandi.
- Lobelia, alkaloids of, except substances containing less than 0·5 per cent. of the alkaloids of lobelia.
- Morphine except substances containing less than 0·2 per cent. of morphine calculated as anhydrous morphine.
- Nicotine.
- Papaverine except substances containing less than 1 per cent. of papaverine.
- Pomegranate, alkaloids of, except substances containing less than 0·5 per cent. of the alkaloids of pomegranate.
- Quebracho, alkaloids of.
- Sabadilla, alkaloids of, except substances containing less than 1 per cent. of the alkaloids of sabadilla.
- Solanaceous alkaloids, not otherwise included in this Schedule, except substances containing less than 0·15 per cent. of solanaceous alkaloids calculated as hyoscyamine.
- Stavesacre, alkaloids of, except substances containing less than 0·2 per cent. of the alkaloids of stavesacre.
- Strychnine except substances containing less than 0·2 per cent. of strychnine.
- Thebaine except substances containing less than 1 per cent. of thebaine.
- Veratrum, alkaloids of, except substances containing less than 1 per cent. of the alkaloids of veratrum.
- Yohimba, alkaloids of.
- Allylisopropylacetylurea.
- Amidopyrine; its salts.
- Amino-alcohols, esterified with benzoic acid, phenylacetic acid, phenylpropionic acid, cinnamic acid or the derivatives of these acids, except in substances containing less than 10 per cent. of esterified amino-alcohols.
- Antimonial poisons except substances containing less than the equivalent of 1 per cent. of antimony trioxide.
- Arsenical poisons except substances containing less than the equivalent of 0·01 per cent. of arsenic trioxide.
- Barbituric acid; its salts; derivatives of barbituric acid; their salts; compounds of barbituric acid, its salts, its derivatives, their salts, with any other substance.
- Barium, salts of.
- Cannabis; the resin of cannabis; extracts of cannabis; tinctures of cannabis; cannabin tannate.
- Cantharidin except substances containing less than 0·01 per cent. of cantharidin.
- Cantharidates except substances containing less than the equivalent of 0·01 per cent. of cantharidin.
- Digitalis, glycosides of, except substances containing less than 1 unit of activity (as defined in the British Pharmacopœia) in 2 grammes of the substance.
- Dinitrocresols; dinitronaphthols; dinitrophenols; dinitrothymols.
- Ergot; extracts of ergot; tinctures of ergot.
- Guanidines, the following: polymethylene diguanidines, dipara-anisyl-phenetyl guanidine.
- Hydrocyanic acid except substances containing less than 0·1 per cent. of hydrocyanic acid (HCN); cyanides except substances containing less than the equivalent of 0·1 per cent., weight in weight, of hydrocyanic acid (HCN); double cyanides of mercury and zinc.
- Lead, compounds of, with acids from fixed oils.
- Mercuric chloride except substances containing less than 1 per cent. of mercuric chloride; mercuric iodide except substances containing less than 2 per cent. of mercuric iodide; nitrates of mercury except substances containing less than the equivalent of 3 per cent., weight in weight, of mercury (Hg); potassio-mercuric iodides except substances containing less than the equivalent of 1 per cent. of mercuric iodide; organic compounds of mercury except substances containing less than the equivalent of 0·2 per cent., weight in weight, of mercury (Hg).
- Metanitrophenol; orthonitrophenol; paranitrophenol.
- Nux Vomica except substances containing less than 0·2 per cent. of strychnine.
- Opium except substances containing less than 0·2 per cent. of morphine calculated as anhydrous morphine.
- Oubain.
- Oxycinchonic acid, derivatives of; their salts; their esters.
- Phenetidylphenacetin.
- Phenylcinchoninic acid; salicyl-cinchonic acid; their salts; their esters.
- Phenylethyldantoin; its salts; its acyl derivatives; their salts.
- Picrotoxin.
- Savin, oil of.
- Strophanthus, glycosides of.
- Thallium, salts of.
- Tribromethyl alcohol.

## FOURTH SCHEDULE

*Substances required by Rule 12 to be sold by retail only upon a prescription given by a qualified medical practitioner, registered dentist or registered veterinary surgeon*

- Amidopyrine; its salts.
- Barbituric acid; its salts; derivatives of barbituric acid; their salts; compounds of barbituric acid, its salts, its derivatives, their salts, with any other substance.
- Dinitrocresols; dinitronaphthols; dinitrophenols; dinitrothymols.
- Phenylcinchoninic acid; salicyl-cinchonic acid; their salts; their esters.
- Sulphonal; alkyl sulphonals.

A leaflet prepared by the Pharmaceutical Society gives the following list of some of the substances coming within the Fourth Schedule, in the form in which they are usually prescribed:—

- |                                  |                         |                               |
|----------------------------------|-------------------------|-------------------------------|
| Acitophosan.                     | Didial.                 | Pernocton.                    |
| Agotan.                          | Diethylbarbituric acid. | Pfanodorm.                    |
| Alepsal.                         | Diethylamonylurea.      | Phenobarbital.                |
| Algodorm.                        | Dinitrocresols          | Phenobarbitone.               |
| Allobarbitone.                   | dinitronaphthols;       | Phenquin.                     |
| Allonal.                         | dinitrophenols;         | Phenylcinchoninic acid.       |
| Amidophen.                       | dinitrothymols.         | Phenyl-ethyl-barbituric acid. |
| Amidopyrine.                     | Disulphamin.            | Prominal.                     |
| Amytal.                          | Ditonal.                | Proponal.                     |
| Anegrine.                        | Diogenal.               | Pyramidon.                    |
| Angiolylin.                      | Ephepyrin.              | Quadro-nox.                   |
| Anotal.                          | Eupaco.                 | Quinophan.                    |
| Arcanol.                         | Euvaleol elixir B.      | Rutonal.                      |
| Asciatine.                       | Evipan.                 | Salicylcinchonic acid.        |
| Atocin.                          | Gardan.                 | Sandoptal.                    |
| Atophan.                         | Gardenal.               | Sciatego.                     |
| Atophanyl.                       | Gorun cachets.          | Sedal.                        |
| Atoquinol.                       | Hebural sodium.         | Sinepan.                      |
| Barbital.                        | Hemynpnone.             | Sonnacetin.                   |
| Barbitone and soluble barbitone. | Ipral.                  | Somnifaine.                   |
| Barbituric acid.                 | Leucotropin.            | Somnifene.                    |
| Benzedo compound.                | Luminal.                | Somnosal.                     |
| Cafinal.                         | Malonal.                | Sonalgin.                     |
| Chineonal.                       | Malonurea.              | Soneryl.                      |
| Chloroxyl.                       | Medinal.                | Sulphonal; alkyl sulphonals.  |
| Cibalgin.                        | Merbaphen.              | Tetronal.                     |
| Cinchophen.                      | Methylsulphonal.        | Theogardenal.                 |
| Cinchosal.                       | Nembutal.               | Theominal.                    |
| Codeonal.                        | Neocinchophen.          | Theotone.                     |
| Compral.                         | Noonal.                 | Tolysin.                      |
| Creslumin.                       | Neophenoquin.           | Trigemin.                     |
| Cyclobarbital.                   | Neoquinophan.           | Trional.                      |
| Dekrysil.                        | Neurinase.              | Veramon.                      |
| Dial.                            | Novasulol.              | Veronal.                      |
| Dialacatin.                      | Novatophan.             | Verongen.                     |
| Diallylbarbituric acid.          | Optaldon.               | Veropyron.                    |
| Dibromin.                        | Optinoktin.             |                               |
|                                  | Pentobarbital.          |                               |

## GENERAL MEDICAL COUNCIL

SUMMER SESSION, MAY 26TH-29TH, 1936

At the conclusion of the presidential address summarised in our last issue a vote of thanks to Sir NORMAN WALKER was proposed by Dr. Letheby Tidy and seconded by Mr. R. E. Kelly. Sir Robert Bolam was then elected chairman of business, and the Standing Orders were suspended in order that the Council might arrange to meet on Wednesday and Thursday mornings. An application from Mr. Sylvester Davidson Fairweather for the removal of his name from the Register as he had ceased to practise was agreed to. After deliberation in camera the President announced the restoration to the Dentists Register of the name of William McCulloch Lawson.

## Cases Referred by the Dental Board

*The Case of James Alexander Randolph Allison*, registered as of 26, Seedhill-road, Paisley, "Dentist 1921," who had pleaded guilty and been convicted of fraud at the Greenock Sheriff Court on Dec. 11th, 1935, and sentenced to six weeks' imprisonment. He had not appeared nor been represented at the inquiry of the Dental Board. His name had been erased from the Dentists Register previously and the Council had consented to its restoration at the November, 1935, session. The Board recommended the erasure of his name again. He was not present. Mr. Harper, solicitor to the Council, explained the facts, and the President, after deliberation in camera, announced that the Registrar had been directed to erase Mr. Allison's name.

*The Case of John Drain*, registered as of 21, Albert-street, Alexandria, Dumbarton, "Dentist 1921," who had been sentenced at Woking on Feb. 22nd, 1936, to three months' imprisonment for embezzlement and theft from his employer. He had pleaded guilty. He had not attended the inquiry nor been represented, and the Board recommended the erasure of his name from the Register. Mr. Drain was not present nor represented. Mr. Harper laid the facts before the Council, which, after deliberation, decided to erase the name of Mr. Drain from the Dentists Register.

*The Case of Lionel Richard Sanders*, registered as of 350, High-road, Tottenham, London, N.17, "Dentist 1921," who had appeared before the Dental Board on the following allegations:—

1. You committed adultery with Gwendoline Lanston, a married woman, of which adultery you were found guilty by the decree of the Probate Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated Dec. 17th, 1935, in the case of Sanders, Nora Silk v. Sanders, Lionel Richard, in which you were respondent.
2. The said Gwendoline Lanston was a patient of yours from July to September, 1933. Alternatively: 3. (a) By carrying on immoral and improper relations with Gwendoline Lanston at the premises 350, High-road, Tottenham, where you conducted your practice as a dentist; (b) by signing and giving to the said Gwendoline Lanston on Sept. 23rd, 1933, a receipted account purporting to be for professional attendance on her in order to conceal and dissemble your true association with her. And that in relation to the facts so alleged you have been guilty of infamous or disgraceful conduct in a professional respect.

The complainant was William Lanston.

The Dental Board had found the facts alleged proved to their satisfaction and recommended the erasure of Mr. Sanders's name.

Mr. Sanders attended, accompanied by Mr. Wynn Werninck, counsel, instructed by Messrs. Bein and Lawrence, solicitors. Mr. Werninck addressed the Council, questioning whether the admitted misconduct could be said to be in a professional respect. The association had begun before respondent knew the lady was married, and the professional receipt in evidence had been given only in an attempt to make the husband think she was a patient which in fact she was not. Mr. Winterbottom (solicitor to the Council) pointed out that the Dental Board had not made any pronouncement as to whether Mrs. Lanston was a patient or not.

After deliberation in camera the President announced that the Registrar had been directed to erase Mr. Sanders's name from the Dental Register.

## Cases Referred from Previous Sessions

*The Case* (adjourned from May 30th, 1935) of *James Francis Patrick Devlin*, registered as of Old Chapel House, Richmond Hill, Leeds, 9, M.B., B.Ch. 1916, N.U. Irel., who had been summoned to appear before the Council on a conviction at Huddersfield in January, 1935, for being under the influence of drink to such an extent as to be incapable of having proper control of a car of which he was in charge.

The Council had found the charge proved and had postponed judgment for a year. Dr. Devlin now appeared, and had submitted the required testimonials as to his conduct in the interval. He repeated his apologies and his determination to act on the warning he had received. After deliberation in camera the President announced that the Council had decided not to erase Dr. Devlin's name.

*The Case* (adjourned from May 29th, 1935) of *William Graham*, registered as of Bridge House, Manor-road, Tynemouth, M.B., B.S. 1923, U. Durh., who had been summoned to appear before the Council as a result of various convictions for motoring offences. The charges had been found proved and judgment had been postponed for twelve months.

Dr. Graham appeared, accompanied by Mr. Oswald Hempson, solicitor, who put in the required testimonials and reiterated on behalf of his client his promise to abstain altogether from alcohol. He also drew attention to the serious punishments imposed by the court, which included disqualification for life from holding a driving licence. After deliberation, the President announced that Dr. Graham's name would not be erased.

*The Case* (adjourned from May 28th, 1935) of *Alexander Beck Cluckie*, registered as of 14, Gay-street, Bath, M.B., Ch.B. 1908, U. Glasg., who had been summoned to appear before the Council on account of convictions in the Bath City Police-court for drunkenness while in charge of a car and other motoring offences. The charge had been found proved and judgment postponed for a year. Dr. Cluckie now appeared, bringing seventeen testimonials, and reiterated his vow of abstinence. His name was not erased.

*The Case* (adjourned from May 30th, 1935) of *William Mervyn Crofton*, registered as of 22, Park-square, London, N.W.1, M.B., B.S. 1904, R.U. Irel.; M.D. 1911, N.U. Irel., who had been summoned on a charge (brought by the Medical Defence Union) of advertising by press interviews, public notices, and a speech to opticians. Dr. Crofton was not present and had not been asked to attend. The Council considered his testimonials in camera as they were only interim reports, final judgment having been postponed at the 1935 hearing for two years.

*The Case* (adjourned from May 29th, 1935) of *Oladipo Lahanmi*, registered as of 2, Levenshulme-road, Gorton, Manchester, L.M.S.S.A. Lond., 1932, who had been summoned to appear on charges of stealing microscopes from the Liverpool School of Tropical Medicine, for which he had been convicted and fined at the police-court. The charge had been found proved but the Council, in consideration of youth and other circumstances, had postponed judgment. Dr. Lahanmi now submitted the testimonials required of him and appeared. After deliberation the Council decided not to order the erasure of his name.

*The Case* (adjourned from May 29th, 1935) of *Samuel Patrick McGrath*, registered as of 54, Kinross-avenue, Worcester Park, Surrey, M.B., B.Ch. 1924, N.U. Irel., who had appeared on a charge of unprofessional conduct after convictions for driving a car under the influence of drink. Judgment had been postponed, subject to the usual provisos. Dr. McGrath appeared, accompanied by Mr. Oswald Illempson, solicitor, who produced testimonials and voiced his client's assurances for the future. Dr. McGrath's name was not removed.

*The Case* (adjourned from May 29th, 1935) of *Cecil John Rhodes Morrison*, registered as of c/o National Bank of India, 26, Bishopsgate, London, E.C.2, L.R.C.P. Edin., 1925; L.R.C.S. Edin., 1925; L.R.F.P.S. Glasg., 1925, who had been summoned to appear before the Council as a result of convictions for drunkenness. Dr. Morrison attended, with the testimonials that had been required of him, and the President announced that his name would not be erased.

*The Case* (adjourned from June 1st, 1934, and May 28th, 1935) of *George Francis Donaldson Perrott*, registered as of 25, Bromefield, Stanmore, Middlesex, M.R.C.S. Eng., 1928; L.R.C.P. Lond., 1928, who had been summoned to appear before the Council on similar charges of drunkenness. Dr. Perrott attended, accompanied by Mr. Levy Teesdale, solicitor, who gave his client's assurance as to good conduct in future, and put in the testimonials asked for by the Council. Dr. Perrott's name was not erased.

### New Penal Cases

#### CHARGES OF DRUNKENNESS

*The Case of Alan Gray*, registered as of 65, Moston-lane, Blackley, Manchester, M.B., B.S. 1925, U.Durh., who had been summoned to appear before the Council on the following charge:—

That you were convicted, after pleading guilty, of the following misdemeanour, viz., on Jan. 13th, 1936, at the Manchester City Police-court, of being under the influence of drink whilst in charge of a motor-car, and were fined £20 and 5s. costs and were disqualified for holding a driving licence for twelve months.

Dr. Gray was not present. Mr. Harper said that the Notice of Inquiry had been acknowledged by a Mrs. Gray, who had forwarded it to the respondent on a ship which was at sea. It was agreed to postpone the case.

*The Case of John Muir MacKenzie*, registered as of Hollymoor Mental Hospital, Northfield, Birmingham, M.B., Ch.B. 1921, U. Glasg., who had been summoned to appear before the Council on the following charge:—

That you were convicted, after pleading guilty, at the Birmingham Police-court of the following misdemeanours: (1) on July 29th, 1933, of being drunk, and were fined 5s. or seven days' imprisonment; (2) on Oct. 29th, 1934, of being drunk, and were fined 10s. or seven days' imprisonment; (3) on Nov. 2nd, 1935, of driving a motor-car

whilst under the influence of drink, and were fined £10 and £1 16s. costs or 28 days' imprisonment, and were disqualified for holding a driving licence for 12 months.

Dr. MacKenzie appeared, accompanied by Mr R. A. Willes, counsel, instructed by Messrs. Barlow, Lyde and Gilbert, agents for Messrs. James Ore, Birmingham. Mr. Winterbottom laid the facts before the Council and read the evidence given by the police officers. Mr. Willes addressed the Council on Dr. MacKenzie's behalf, emphasising that the offence occurred when respondent was off duty, and that respondent had a remarkably high professional reputation and had recently obtained the D.P.M. Lond. and performed valuable research work. He called Dr. T. Yoxall, who said he had known Dr. MacKenzie for ten years, and testified warmly to his excellence as a man and a doctor. To witness's knowledge, respondent could not safely take any alcohol and had now become a teetotaler. Dr. MacKenzie also testified on his own behalf. After deliberation in camera the President announced that the charge had been found proved but judgment would be postponed for 12 months, subject to the usual provisos.

*The Case of David Davidson Watson*, registered as of 55, Corstorphine Hill-gardens, Edinburgh, 12, M.B., Ch.B. 1926, U.St.And., who had been summoned to appear before the Council on the following charge:

That you were convicted (1) of the following offence: on Dec. 2nd, 1933, at the Sheriff Court, Edinburgh, of driving a motor-car whilst under the influence of drink, and were fined £15; (2) of the following misdemeanour: on March 30th, 1936, at the Wakefield City Police-court, of being in charge of a motor-car whilst under the influence of drink, and were fined £20 and £2 1s. costs and disqualified for holding a driving licence for 12 months.

Dr. Watson appeared in answer to his Notice; Mr. Winterbottom laid the details before the Council, and Dr. Watson spoke on his own behalf, and said he had had no intention of driving the car and was not in it. He answered questions and gave his assurance for the future. Judgment was postponed for 12 months, subject to the usual provisos.

*The Case of William Douglas*, registered as of 282, Goldhawk-road, Shepherd's Bush, London, W.12, M.B., Ch.B. 1921, U.Edin., who had been summoned to appear before the Council on the following charge:—

That you were convicted of the following misdemeanours, viz.: (1) On March 19th, 1935, at Beaconsfield Police-court, of driving a motor-car whilst under the influence of drink (date of offence, Feb. 27th, 1935), and were fined £10 and £3 4s. costs, and disqualified for holding a driving licence for one year; and (2) on Dec. 30th, 1935, at the Bucks Quarter Sessions held at Aylesbury, of driving a motor-car whilst under the influence of drink (date of offence, Dec. 7th, 1935), and were sentenced to three months' imprisonment and disqualified for holding a driving licence for two years.

Dr. Douglas appeared, and Mr. Harper laid the facts before the Council. The respondent repeated the assurances of future good behaviour which he had already written to the Council, and judgment was suspended until May, 1937, subject to the usual provisos.

#### ALLEGED BREACH OF D.D.A. REGULATIONS

*The Case of Joseph Hirschmann*, registered as of 127, Maida-vale, London, W.9, M.B., B.Ch., 1920, U.Dub., who had been summoned to appear before the Council on the following charge:—

That you were on Feb. 28th, 1936, convicted, after pleading guilty, at the Marylebone Police-court (a) of failing to enter in register particulars of dangerous drugs

obtained from F. E. Dee, chemist (date of offence, August 31st, 1935); (b) of failing to enter in register particulars of dangerous drugs obtained from C. J. Hewett and Sons, Ltd., chemists (date of offence, Sept. 12th, 1935); and (c) of failing to enter in register particulars of dangerous drugs obtained from C. J. Hewett and Sons, Ltd., chemists (date of offence, Sept. 14th, 1935), contrary to the Dangerous Drugs (Consolidation) Regulations, 1928, and the Dangerous Drugs Acts, 1920-25, and were fined £50 and £10 10s. costs in respect of each of the three offences.

Dr. Hirschmann appeared, accompanied by Dr. Reginald Hearn, counsel, instructed by Messrs. Vivian J. Williams and Co.

Mr. Harper said that the police-inspector had said that the police had evidence that the respondent did not administer proper medical treatment to certain addicts under his care, but increased their doses. The charges concerned three separate quantities of morphine sulphate tablets: grs. 54, grs. 200, and grs. 144. The respondent had pleaded guilty. The Home Office had withdrawn his authorisation to use dangerous drugs, and had notified the Council.

Dr. Hirschmann gave evidence on his own behalf. He said that he had failed to enter the grs. 54 in his book because he had thought they were ordered by a prescription given to a patient instead of, as in fact they were, by an order to supply to himself. The grs. 200 had been sent him by mistake and had never been opened. He had failed to enter the grs. 144 through carelessness; it had all been given to a patient with rectal cancer shortly before operation. At the hearing before the magistrates his counsel had advised him to plead guilty as the offence was only a technical one. He had actually been carried into court, suffering from the effects of a severe motor accident. Instead of treating the charge as merely a breach of regulations, the magistrate had taken a serious view of it and had not only fined him fifty pounds and ten guineas costs, but demanded payment that day. The respondent had only complied with great difficulty. This unfortunate plea of guilty had made his appeal of no avail and deprived him of the right to reopen the case before the Council.

The Council, however, examined Dr. Hirschmann on the facts at considerable length. After an adjournment to enable him to fetch his books, he answered questions by the legal assessor, Dr. Bone, and other members of the Council relating to the entries about dangerous drugs. He gave details of the six addicts he had been treating at the material time. His books, he said, had been regularly inspected by the N.H.I. regional medical officer. He had never in his life started a case on morphia or heroin.

Dr. Philip Hamill testified to the good character of respondent and said the doses given were quite suitable for addicts of long standing, so far as his knowledge went.

After deliberation the Council did not see fit to order the erasure of Dr. Hirschmann's name.

#### CHARGES OF ADULTERY

*The Case of Walter Edgar Masters*, registered as of Old Hill House, Chislehurst, Kent, L.M.S.S.A. Lond., 1913; M.R.C.S. Eng., 1918; L.R.C.P. Lond., 1918; D.P.H. R.C.P.S. Eng. 1928, who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner (1) you committed adultery with Hetty Elizabeth Sykes, a married woman, of which adultery you were found guilty by the decree of the Probate Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated March 3rd, 1936, in the case of Sykes v. Sykes and Masters, in which you were the co-respondent; (2) you stood in

professional relationship from March to December, 1933, with the said Hetty Elizabeth Sykes, who was a patient during that period at Old Hill House Nursing Home, Chislehurst, Kent, of which you were the medical officer. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

Respondent was not present.

Mr. Winterbottom explained the steps taken to acquaint Dr. Masters with the date of the inquiry and put in receipts for the registered letters sent to his only known addresses. The Standing Orders had been complied with and the Council, after deliberation in camera, decided to proceed with the case. Mr. Winterbottom put in a copy of the divorce decree and adduced facts in support of the professional relationship from the evidence in court of an employee of the nursing-home. He then called Mrs. Masters, who testified to her statutory declaration and the nursing home case-book. She said she had run the home for inebriates since her husband left her, as matron and proprietor; the case-book showed clinical notes in her husband's writing relating to Mrs. Sykes as a patient entering the home on March 20th, 1933, and the last entry being dated Dec. 14th.

After deliberation the Council decided to erase Dr. Masters's name from the Register.

*The Case of David Gaston*, registered as of 55, Bromley-road, Catford, London, S.E.6, M.B., B.Ch. 1914, Q.U. Belf., who has been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner (1) you committed adultery with Queenie Grace Painter, a married woman, of which adultery you were found guilty by the decree of the Probate Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated April 11th, 1935, and made absolute on Oct. 28th, 1935, in the case of Painter v. Painter and Gaston, in which you were the co-respondent; and (2) you stood in professional relationship from 1927 to 1934 with the said Queenie Grace Painter and her husband, Frederick Thomas Painter. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainant was Mr. Frederick Thomas Painter.

Dr. Gaston attended, accompanied by Mr. J. C. Smuts, instructed by Messrs. J. and C. Dodd.

Mr. Winterbottom said the facts were admitted, and called complainant.

Frederick Thomas Painter testified to his statutory declaration, which said that his parents and family had been under Dr. Gaston's care before his marriage and up to 1934. In 1927 his wife went to the doctor professionally, but had not previously met him. Later the two couples became friendly and went about together. Throughout, the Painters remained Dr. Gaston's patients. The divorce proceedings had been defended by Dr. Gaston only on the question of damages. In cross-examination he said that if Mrs. Painter had met Dr. Gaston before 1927 it was without his knowledge.

Mr. Smuts addressed the Council, urging that the relationship with Mrs. Painter had started before respondent began practice in Catford and did not arise out of a professional introduction. The relationship had lasted eleven years and there was no suggestion of any other woman in respondent's life. All relationship with Mrs. Painter had now ceased and Mrs. Gaston was living with her husband. The adultery had only lasted for a year and respondent had ceased practice and left the neighbourhood to avoid any scandal on his profession. He had already

suffered heavily through divorce damages and loss of livelihood, and deeply regretted his offence.

After deliberation in camera the President announced that the Registrar had been directed to erase Dr. Gaston's name from the Register.

*The Case of William James Woodward*, registered as of Enfield Villa, Station-road, Billingham-on-Tees, Co. Durham, M.B., Ch.B. 1928, U.Glasg., who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner (1) you committed adultery with Elizabeth Mott, the wife of Wilson John Mott, on various dates between August, 1933, and January, 1934, at 3, North-terrace, Stockton, at Billingham, and at High-street, Norton, your surgeries, and at 16, Balder-road, Norton, the residence of the said Elizabeth Mott and her family; (2) Miss Linda Mott, a daughter, and Gordon, a son of the said Mr. and Mrs. Mott, were patients of yours, and the said Mrs. Mott had occasion to call on you at your surgeries on behalf of and in relation to the health of her said daughter and her daughter's baby; (3) you arranged meetings and committed adultery with the said Elizabeth Mott at your said surgeries in order to conceal and disseminate your improper and immoral association with her. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainant was Mr. Wilson John Mott.

Respondent was present, accompanied by Mr. W. A. Macfarlane, counsel, instructed by Messrs. Le Brasseur and Oakley, on behalf of the London and Counties Medical Protection Society.

Mr. Harold Darcy, solicitor, on behalf of the complainant, a relieving officer, said that at the end of the summer of 1933 respondent was in practice in Stockton in partnership. Arbitration proceedings between the partners came to a head at the end of the year and it became known to complainant that Mrs. Mott was being approached as a witness in these proceedings. Respondent was not the medical attendant of Mr. or Mrs. Mott, but his partner was the daughter Linda's panel doctor. Linda always lived with her grandparents. Mrs. Mott had visited the surgery about the girl and had there been told that the partner was not available and had been attended to by Dr. Woodward, then and on two subsequent visits. On the third visit respondent made improper advances, and misconduct occurred. He had asked if he might visit her at home. Thereafter visits had been exchanged frequently and messages had been sent by various hands. On June 13th, 1934, Mr. Mott had written to Dr. Woodward asking for an explanation of the frequent visits of which he had been unaware, and threatening to report the facts to the General Medical Council. The reply had been sent by the solicitors to the London and Counties Medical Protection Society and had denied the allegations, mentioning that a Mrs. Mott had already complained to the Council and the Penal Cases Committee had found no case to answer. Actually, said Mr. Darcy, it was not Mrs. Mott who had complained but her sister, who had had no business to interfere. On Feb. 18th, 1935, Mrs. Mott had visited the surgery with her sister to inquire about rumours that she had received a large sum of money from the doctor for some purpose in connexion with the arbitration proceedings. She had had a cold reception, and next day had had a letter from his solicitors asking her to discuss any matter with them and not with the doctor. Mrs. Mott had replied at once, and perhaps indiscreetly, using very strong language.

Mr. W. J. Mott testified to his statutory declaration and produced a medical certificate that one of his

witnesses was unable to attend. He said he had been married 24 years and had three children. He had never seen Dr. Woodward until the previous day but the children had been on the panel of Dr. Woodward's former partner. The son's name had been removed from the panel at the request of Dr. Woodward in May, 1935, but witness had not understood why. "Words" with his wife had ensued and, in consequence of what she then said about the respondent, witness had written to the doctor and made a complaint to the Council.

Cross-examined, he agreed that his son Gordon had joined respondent's panel in January, 1935. The complaint of adultery and visiting ended with December, 1934. His daughter had been a panel patient of the partner and from time to time had been attended by respondent; she did not live with him. He knew nothing more about professional attendance on her in 1934. He had pressed his wife considerably to find why Gordon had been struck off Dr. Woodward's panel. He knew nothing of the complaint brought by his wife's sister; he had learned of it about the time he had made his own complaint. His wife had told him she had committed adultery with the doctor, but he had not mentioned adultery in his angry letter to the doctor. She had been "absolutely furious" with Dr. Woodward. Up to that time he had had no suspicions of his wife. In the previous year he had been to Mr. Watson, a solicitor, to try to find out about the arbitration case and what statement his wife had made. He had heard that allegations about his wife and respondent formed part of the arbitration case; his wife had asked if she might make a statement saying that Dr. Woodward had only called there by mistake, looking for Linda, and was not otherwise calling there. Later, he had got to know that suggestions of adultery with the partner were being made, but he had not consulted Mr. Watson about this or known of it at the time. He had, he admitted, asked Mr. Watson if he could take slander proceedings against the partner if the allegations proved untrue; but he had not asked if he could take divorce proceedings against him. He had treated the story of adultery with the partner as a joke. He did not know yet what had been said in the arbitration statements.

Re-examined, he agreed that his wife had told him a number of lies.

In reply to Mr. H. L. Eason, he said that at the material time no member of his family living in his house was a patient of Dr. Woodward's.

Mrs. Elizabeth Mott said that she had gone to the surgery in August, 1933, about Linda and had seen respondent, as his partner was ill. Respondent had known she was Linda's mother. She had gone again three weeks later for a bottle of medicine for Linda, at the afternoon surgery hour. He had kissed her, pulled her on his knee, and had connexion with her. She had become afraid but he had told her to stick to him and say what he told her to say. She had visited him dozens of times at the Billingham surgery in the evening; he had hung his overcoat on the door to cover the keyhole. He had sent messages by men and a little girl. In February, 1935, she and her sister had gone to the surgery in consequence of rumours and she had said: "This is my sister. Will you tell her I didn't get £300 for keeping my mouth shut?"

Cross-examined by Mr. Macfarlane, she said she said no more at that interview. She denied that she had committed adultery with the partner, but admitted that she had declared in writing that she

had done so, maintaining that respondent had told her to do so and assured her there never would be arbitration proceedings. She would not have sworn to this in oral evidence. She had not said at the county court that she wanted to "down" the partner. She admitted writing the letter to respondent in which she said: "Mr. Mott and neighbours say you have been with me, and I will. When you upset me you do it to the wrong one." She had gone to Mr. Watson to try to reopen the arbitration case because she objected to detectives inquiring about this letter. Money had never been mentioned in Mr. Watson's office. Certainly, she had been very excited. Mr. Watson had said: "What is your figure, Mrs. Mott?" She had said she was going straight to the partner. She had not accused any other doctors in the Stockton area of having intercourse with her. Her daughter Linda had never gone with her to see respondent during the pregnancy, or at any time before the baby was born in August, 1933. Respondent did not take his holidays in September; he was at the surgery. He had asked her to call again; he did not say why but she could guess. "If a man asks a lady to call again, she *can* guess, can't she?" This was the second time she had seen him, in the surgery, and nothing familiar had been said or done. Next time, intercourse took place in the Stockton surgery, in the basement of the partner's house. It was possible to see into the surgery from the area steps; there was no frosted glass. While intercourse took place there, two patients had been waiting in the adjoining waiting-room, in the afternoon. She had not been there longer than ten minutes in all. The next time the partner had entered through the communicating door from the house and again there had been patients waiting. The partner had said "sorry" and gone out again. After that, respondent had suggested coming to her home in the mornings, coming by car with a chauffeur four or five times. There was no patient of his in the house. She had another doctor. The neighbours had thought it very odd and she had told them the doctor came on Mr. Mott's business. Linda's baby had had a facial naevus but she had never been to the surgery with Linda about it; nor had he and she ever talked of the baby. In her statement she had emphatically denied any improper behaviour on respondent's part, but she had only signed it because he asked her to as a friend. She had written it and he had told her what to put. A large part of it was untrue. Mrs. Collins was willing to oblige witness by saying she had seen intercourse take place, though in fact she had not been there at all. Mrs. Woodward had never accompanied the doctor on his visits. Intercourse had sometimes taken place standing up at the desk and sometimes on the floor.

In reply to the legal assessor, Mr. Macfarlane explained the arbitration case. Respondent had been junior partner and there had been three surgeries. Differences had arisen from financial matters irrelevant to this case and from the charges of immorality in a professional respect made by Mrs. Mott against the partner. Respondent in April, 1934, had claimed arbitration with a view to dissolving the partnership. The partner had made cross-charges of slander against respondent in saying he (the partner) was unfit to look after patients, his prescriptions were no good, and he was going with women. In June and November further cross-charges of financial irregularities were added. The case was to be heard in December, 1934, but had been settled by counsel before hearing, and all allegations had been withdrawn. By this time Dr. Woodward had come to

doubt some of the evidence which previously he had believed to be true. Mrs. Mott had repeatedly come to the surgery to pass on bits of gossip about the arbitration allegations, and had asked the solicitor not to write to her as she did not want her husband to know.

Mrs. Alice Collins testified to having waited for Mrs. Mott outside the surgery on several occasions. In January, 1935, she had told respondent to behave himself with Mrs. Mott. He had asked, "Do you believe all she says?" and witness had said "Yes." She had seen his car go to Mrs. Mott's house and been there when he had called.

Cross-examined, she denied that Mrs. Mott was dissatisfied with the result of the arbitration and admitted telling the solicitor that the partner had committed adultery with Mrs. Mott twice in her presence but on the second occasion she had been careful not to look. These statements were all lies. In answer to the legal assessor she said that Mrs. Mott had suggested that she should concoct the story about the partner for the arbitration proceedings.

Mrs. Hilda Nicholls, sister of Mrs. Mott, said she had complained to the Council in 1935, and the committee had found the charge groundless. She confirmed her sister's account of the visit to the surgery in January, 1935, and of the visit to Mr. Watson.

After deliberation in camera, without calling on counsel, the President announced that the facts alleged had not been found proved.

#### CONSIDERATION OF THE CURRICULUM

The final report of the Curriculum Committee on the best means of improving the training of medical students was presented to the Council and after discussion at three morning sessions was finally adopted without much change. An interim report<sup>1</sup> had been presented a year ago, on which the licensing bodies and medical schools were asked to give their observations; and a second interim report<sup>2</sup> was laid before the Council last November dealing with these observations, and was also circulated to the licensing and teaching bodies. Observations were made by the Minister of Health, the special committee on medical education appointed by the B.M.A., and the council of the section of radiology of the Royal Society of Medicine, and a memorandum was received from the General Council of the Trade Union Congress. The final report was drafted after considering all these opinions.

#### ADMISSION TO THE CURRICULUM

There was general, though not unanimous, agreement (said the Committee) with the opinion that students should not enter upon the medical curriculum proper before the beginning of the term in which they attain the age of 18 years, and the Committee recommended that the present minimum age of 17 years should be altered. It also considered that the Council would be justified in inviting the licensing bodies to decide either to require registration of medical students or to encourage it officially. The Committee agreed with the widely expressed opinion that the general education of the student should not cease at too early an age, and consequently recommended that at the pre-registration examination, which at present consists of scientific subjects, one or two subjects of general education should be taken at a standard higher than that of the preliminary

<sup>1</sup> THE LANCET, 1935, i, 1403.

<sup>2</sup> Ibid., 1935, ii, 1425.

examination. As, however, this rule would impose great practical difficulty on students who enter universities, university colleges, or medical schools before receiving instruction in pre-registration scientific subjects, the report recommended that it should not apply to such students.

#### PRE-CLINICAL STUDIES

The existing resolutions provide that a minimum period of three years shall in every case be available for study after the student has completed his professional examinations in anatomy and physiology. Several licensing bodies, the Committee reported, hold their professional examinations at the end of the fifth term, and the sixth term is often occupied by a course of instruction in clinical methods and physical signs which students must attend before they can be appointed clerks or dressers. Such courses are also commonly held before admission to clinical appointments by licensing bodies which hold their professional examinations at the end of the sixth term. The Committee expressed the opinion that such courses, while valuable and necessary if no such instruction has been given, have not effected an association between the professional scientific subjects and the clinical subjects, or removed the block between the two divisions of the medical curriculum proper. It accordingly recommended that the period of study of the professional scientific subjects should be two years, and that throughout the second year instruction should be given designed to effect the association which is desirable between the subjects of the two periods. In outlining the methods which it recommended, the Committee made clear by the form of the draft resolutions that it did not intend that instruction and examination in systematic medicine and pathology should be given at this period. In laying down what the courses in human anatomy and human physiology should include, it recommended that instruction should be given in the elements of clinical examination, including physical signs, the use of the stethoscope, ophthalmoscope, and similar instruments, and the examination of body fluids; normal reactions of the body to injury and infection as an introduction to general pathology and bacteriology; and an introduction to pharmacology. This instruction should illustrate that given in anatomy and physiology and introduce later studies. It is to be arranged jointly by the teachers of anatomy and physiology and the teachers of the clinical subjects throughout the second year, and the amount of time given to it should be approximately one-third of the total time available in that year.

#### PERIOD OF CLINICAL STUDIES

Some licensing bodies had expressed the view that residence in hospital was unnecessary where ample clinical material was available. The Committee, however, thought that experience could be gained during residence which would not otherwise be regularly obtainable. The resolution concerning the midwifery course had been amended to specify more clearly the nature of the certificate of attendance on cases of labour which should be given to students. There was no change in the number of cases which should be attended—viz., twenty, of which the first five at least should be attended in the lying-in hospital or ward.

#### DR. TIDY INTRODUCES THE REPORT

Dr. H. LETHEBY TIDY, chairman of the Curriculum Committee, moved that the report be received and

entered on the minutes. The Committee had, he said, interpreted its terms of reference widely, and where it had decided that some alteration should be made in the Medical Acts it had not hesitated to lay its views before the Council. General or normal health was now regarded as one of the most important aims of the medical profession, and the Committee considered that throughout the whole period of study the students' attention should be directed to the importance of the measures by which they could assess or maintain normal health, and the principles and practice of the prevention of disease. Speaking of the length of the curriculum and the belief that it was overloaded, Dr. Tidy remarked that in the medical schools at which a considerable proportion of the students qualified the present length of the curriculum was five years. It could therefore clearly be completed by students who were below the standard of supermen. The proposed changes should not require any increase in length. On the other hand, it had been argued that the curriculum was overloaded with unnecessary subjects, and the question was, what were those subjects. As medicine progressed, some subjects receded in importance and others advanced. It was, however, difficult to name subjects that could be omitted. When pressure was brought to bear on the Committee it was always for the insertion of a new subject, never for the dropping of an old one. Many people were glad to welcome a reduction in the time spent on someone else's subject.

There had, said Dr. Tidy, been a wide demand from the profession and the public for an increase in the standard of general education. If there were really more qualified doctors than the public needed, it was reasonable that the standard of entry should be raised to eliminate the weakest. There actually appeared to be a need for a rise in the standard. The present admission examination, however, was passed at school at 16½ years or earlier, and if the standard were raised these young students would be intensively crammed and the quality of the candidates would not be improved. The better plan was to aim at prolonging the general education, and the Committee proposed to require a higher standard in some subjects of general education taken at the same time as chemistry and physics in the pre-registration days, except for those who took chemistry and physics after leaving school. No doubt this left a loophole, but schoolmasters would probably not be anxious to avoid this reasonable requirement.

#### SIR HENRY BRACKENBURY SUPPORTS IT

SIR HENRY BRACKENBURY, seconding the motion, said that the new proposals, speaking generally, recognised a new outlook on medicine. The introduction of such subjects as genetics, psychology, and methods of maintaining health was a step in the direction desired by nearly everybody engaged in medical work. He retained, however, serious doubt whether the two ends of the curriculum would be as good as they ought to be. At the beginning he doubted whether the Committee was going as far as it should. There was probably no serious opposition to the view that not only the general education but also the preliminary scientific studies should be advanced farther than the previous minimum. How far, depended on the Council's conception of what medicine included. They had clearly advanced farther than the idea of medicine as a study of certain pathological processes. Sir Henry defined the science of medicine as the practical application to the human

sphere of the sciences of life. If the medical student were entering a profession which was to be the leading spirit in guiding humanity to complete mental and bodily health, he must have a higher degree of preparation than most other students. Sir Henry still considered that biology ought to be a pre-registration subject, and expressed anxiety about the whole of the two years between 16 and 18. If in certain fundamental directions the mind was not trained at 18 years of age, he said, it never would be trained. The Council must therefore pay great attention to the actual content of the training at the time the student entered upon the medical curriculum proper.

#### DISCUSSION IN THE COUNCIL

A long debate followed, every section of the report being debated separately, including an appendix which showed the new draft resolutions with the proposed alterations marked by a marginal rule.—Dr. E. P. CATHCART wished to abolish completely the training in chemistry and physics in schools for those students who were going on to medicine.—Mr. L. P. GAMGEE thought that instruction in the sciences should be started early and continued without a break.—Dr. DAVID WATERSTON desired to see a further extension of clinical studies. He strongly deprecated the proposal to make the recommendations for pre-registration examinations general all over the country until the Council had ensured that it was within the power of the licensing bodies to adopt the curriculum.

Dr. J. W. BONE remarked that the Committee had introduced a large number of new subjects into the curriculum, many of them of extreme importance. Moreover, the content of the old subjects had been materially increased. There was great danger that the Council would be challenged for putting too many requirements into the new rules. The present curriculum was overloaded, and therefore the proposed curriculum was doubly overloaded. Portions of the old curriculum should have been jettisoned if new matter must be introduced.

Dr. E. K. LE FLEMING warned the Council against losing sight of the wood for the trees. He was still conscious of having learned many things as a student which had helped him to pass his examinations but not to do anything else. The object of the curriculum should be to send out into the country men well equipped to practise general medicine and surgery. Nowhere in the curriculum was this aim suggested. Each specialty and the method of teaching it was well thought out, and great progress had been made in the linking of specialties together, but nowhere did the draft express the idea that the medical curriculum should be devoted to turning out good general practitioners. It had taken the Council 20 years to realise the importance of the National Health Insurance Acts and the obligations which they put upon the panel doctor. Midwifery was likely to pass wholly into the control of the local authorities and become institutionalised, and the political and social problems which had brought this condition about might be traced to inadequate instruction of students in former years. This had been due to the fact that the teachers had not been familiar with the conditions under which the general practitioner would have to carry out the work.

Mr. R. J. JOHNSTONE retorted that all the midwifery teachers whom he knew had ample experience, not only of the conditions in which midwifery was being practised in every class, but also of the practice of difficult midwifery under the same conditions

as those in which the general practitioner practised ordinary midwifery.

Mr. A. W. SHEEN suggested that the debate had served the useful purpose of stirring up the anatomists and physiologists. Teachers of clinical subjects had constantly found that they had to teach anatomy and physiology which the students should already have known. The most important suggestion in the report was the new interlocking of the second-year professional and scientific subjects with the clinical period. He agreed with the principle of applied culture. Life was short, and the education of a doctor could be directed without neglecting the cultural aspect. There were other important factors apart from the curriculum, such as the selection of students, place where they were taught, the provision of teaching, and the choice of teacher. Vaccination should be included with immunisation as a general subject and not given a place by itself. The curriculum would not be overloaded, especially if the students were prevented from wasting their time in operating theatres.

Mr. H. L. EASON said that the University of London could not agree to the raising of the age of entry to 18. Its matriculation examination admitted to every other faculty as well as that of medicine, and the student who had matriculated was entitled to take up his studies. To make an exception of the medical student would be impracticable, and a hardship to poor parents whose anxiety was that their son should earn as soon as possible. He also feared that the present medical graduate was losing sight of the three main branches of medicine. No less than 19 specialties were mentioned by name as essential. If only a fortnight were given to each of them they would occupy the best part of a year to the detriment of the study of the three main branches. He hoped that the inclusion of specialties would be left to the licensing bodies.

#### THE REPORT ACCEPTED

Dr. TIDY, in reply, reminded the Council that efficient doctors were produced under the present resolutions. The modern medical graduate was the best there had ever been, but the Council's duty was, if possible, to turn out a better one. It was untrue that the new resolutions would add a year to the present curriculum. If they had that effect, the licensing bodies were not carrying out the present resolutions. Overloading did not come from the resolutions but from over-teaching.

The report was received and entered on the minutes, and the draft curriculum table was discussed in detail. Textual amendments were made, and Dr. Tidy accepted an amendment by Mr. Eason, on behalf of the Association of Anæsthetists, deleting the requirement that the student should administer ten anæsthetics and substituting the requirement of "a course of theoretical and practical instruction in the administration of anæsthetics." Sir Henry Brackenbury could not persuade the Council to make biology a pre-registration subject. He also moved a long amendment to ensure that the student should: (1) have passed his general schools or matriculation examination and afterwards his examination in chemistry and physics as at present required; (2) continue his general education during the first two years of the curriculum; and (3) study biology seriously during those two years. This amendment was seconded by Dr. Sydney Smith, but after considerable debate it was rejected. The Council, however, amended the heading "Pre-registration Examinations" to "Pre-registration Requirements."

## PUBLIC HEALTH CONGRESS IN EDINBURGH

(FROM OUR SCOTTISH CORRESPONDENT)

THE Lord Provost presided at the joint Congress of the Royal Institute of Public Health and the Institute of Hygiene, held in Edinburgh from May 26th-30th, and in his opening address gave the views of a layman on the problems of rheumatism. After the inaugural meeting the congress divided into sections.

### STATE MEDICINE AND INDUSTRIAL HYGIENE

Sir THOMAS OLIVER, in opening this section with an address on the Foes of Industrial Hygiene, referred to the importance of fatigue in relation to accidents, and dealt with the harmful effects of emanations from radio-active bodies, and of dust containing substances such as white lead. He related how, by the use of sesquisulphide of phosphorus, the manufacture of lucifer matches had ceased to be regarded as a dangerous trade.—Dr. A. MASSEY (Coventry) spoke of the scientific selection of employees. He emphasised the necessity for health education of the workers concomitantly with other measures, and agreed with Sir Thomas Oliver that fatigue was often a precursor of accidents, as of mental and physical illness.—Dr. G. E. OATES (Paddington) read a paper on the Housing Act, 1935.—Dr. E. K. MACDONALD (Leicester) spoke on the Place of the Medical Officer of Health in the Administration of the Municipal Hospital. Far too little use he thought had been made of the facilities afforded under Section 13 of the Local Government Act of 1929.—Dr. CHALMERS WATSON (Edinburgh) read a paper on the Clamant Call for Changes in Medical Education, and at the close of the discussion a resolution was adopted by the meeting to the effect that the medical curriculum should include more specific training in preventive medicine, and urging the General Medical Council to revise the courses accordingly.—Dr. C. WHITE (Port of London) gave an account of the detection of faulty canned foods.—Dr. F. E. CHESTER-WILLIAMS (Bradford), speaking on Public Authorities and Cancer, urged the provision of more and better facilities for the treatment and care of cancer patients in all stages of the disease.

### WOMEN AND CHILDREN AND THE PUBLIC HEALTH

Prof. JAMES YOUNG, taking as the subject of his address the Rôle of the General Practitioner in Obstetric Practice, suggested that there would be increasing openings for those with special training and qualifications as consultants and specialists under the municipal schemes, and referred to the directions in which the general practitioner might find his greatest usefulness in the future.—Dr. JAMES DUNLÓP (Glasgow) spoke in favour of domiciliary midwifery, with a doctor in attendance at every confinement, and Dr. J. A. STEPHEN (Aberdeen) set but the conditions necessary for a satisfactory midwifery service.

Dr. MARGARET BALFOUR dealt with statistics as to the amount of money available for food among the poorer classes, and showed that there was much need for the provision of suitable nourishment for expectant mothers.—Dr. G. W. THEOBALD (London) considered the physical condition of the nation, and suggested that the toxæmias of pregnancy provided a key by means of which many of the problems

concerning nutrition could be unlocked. Not only must a sufficient sum per caput be available for the purchase of food, but the population must be re-educated in its dietary habits. The problem was twofold—cultural and economic. The physician, he remarked, was not a politician, but he himself could not escape from the conviction that something was radically wrong with a system which admitted of poverty in the midst of plenty.

Dame LOUISE MCILROY in her presidential address on Sociological and Medical Aspects of Abortion spoke against the widening of legal facilities for the practice of abortion and dealt with the social conditions which had led to the present propaganda in that direction. Suggesting remedies for the present state of affairs, she said that birth control was the lesser of the two evils, but child bearing should be looked on as a valuable contribution to the State and made as safe and easy as possible. Conditions of life must be adapted to motherhood and proper provision made for the mother.—Anæmia of Pregnant Women of the Working Class in Aberdeen was the subject of a paper by Dr. H. W. FULLERTON and Prof. L. S. P. DAVIDSON (Aberdeen). In their investigations it had been found that anæmia was very common in infants between 9 months and 2 years, and in women of the reproductive age in the poorer classes. They considered a deficiency in iron-rich foods, such as animal protein and vegetables, to be the cause of the anæmia.

Prof. A. J. BALLANTYNE (Glasgow), speaking on present-day problems of eyesight in school-children, deprecated the practice of discouraging higher study, or the choice of a professional career, solely on the presence of high myopia. The greatest wrong that could be inflicted on the high myope was to curtail his education. He urged that ophthalmic examination should begin before the present commencement of school life.

### TUBERCULOSIS

Dr. L. S. T. BURRELL in a presidential address dealt with susceptibility to tuberculosis at various ages and the protection conferred by a mild infection. Although a mild infection did confer some slight if variable protection, a massive infection would produce the disease in the tuberculin reactor as well as in the non-reactor. The greatest source of infection was always the sputum-positive patient.—Dr. P. M. D'ARCY HART (London) referred to the spread of tuberculosis which followed the introduction of the disease into virgin soil in native races, as was seen among the Senegalese troops in Europe in 1914-1918. Such an outbreak might, he feared, occur in Abyssinia unless care was taken about the living conditions of natives in proximity to Italians.—Dr. GEOFFREY TODD (Midhurst) said that collapse therapy had added some years of expectation to life in patients with tuberculosis. But successful treatment still depended much on the patient's confidence in his doctor and in the institution where he was being treated.—Dr. ANDREW MORLAND (London) spoke of the risk taken by tuberculous patients in giving up a sedentary occupation for a strenuous outdoor job, and the wear and tear involved in travelling to and from work the extra distance to have the benefit of fresh air. He advocated adequate midday meals and guidance for the patient how he should spend his leisure hours.—Dr. C. D. S. AGASSIZ (London) spoke on pulmonary tuberculosis in children, and Dr. GEORGE H. DAY (Mundesley) on the part played by the general practitioner in the treatment of tuberculosis.

## RHEUMATISM

Dr. F. J. POYNTON, president of the section dealing with Rheumatism and Allied Diseases, opened a discussion on the Treatment of Chronic Rheumatism. In the same section Dr. C. W. BUCKLEY (Buxton) read a paper on the Spa, and Dr. W. S. C. COPEMAN and Mr. T. J. O'REILLY (London) spoke on the work of the British Red Cross Clinic for Rheumatism.—In a paper on Rheumatic Heart Disease in Childhood, Dr. H. L. WALLACE (Edinburgh) laid stress on the high incidence of rheumatic disease in childhood. He considered that the child suffering from rheumatic heart disease was the victim of wanton neglect on the part of the community. He had found that 25 per cent. of all rheumatic children died from heart disease before they left school, while a further 30 per cent. were crippled by heart disease for the remaining part of their lives. The ideals to be aimed at were two—the easing of the burden which had to be borne by the cardiac cripple, and the prevention of rheumatic heart disease occurring at all.

## MEDICINE AND THE LAW

## The Burden of Proving Insanity

IN *Sodeman v. the King* (on May 28th) the Judicial Committee of the Privy Council declined a somewhat optimistic invitation from Australia to vary the legal rules of the criminal responsibility of the insane. The prisoner was convicted of murdering a girl aged 6½ years in circumstances of brutality. He took her for a ride on a bicycle, strangled her, tied up her body in a curious way, stuffed some of her clothing into her mouth, and left her for dead. He had committed three similar murders, all characterised by identical method. His appeal from the death sentence was rejected by the full court of the State of Victoria, and the High Court of Australia refused him leave to appeal to the Privy Council. His application to the Privy Council last week for special leave to appeal was one of a kind which the Judicial Committee in Downing-street does not welcome. The judges of that supreme tribunal do not regard themselves as a Court of Criminal Appeal; they refuse to re-hear cases without the advantage of having seen the witnesses; the grounds on which they interfere in criminal proceedings are severely limited.

The appellant's complaint was that the trial judge had misdirected the jury as to the burden of proof; he had also directed them on delusions, whereas the accused had no delusions but merely a mind which could not resist doing these meaningless acts. His counsel pressed for the enlargement of the "rules in *McNaghten's case*"; he desired to engraft the further rule that, where a man knew that he was doing what was wrong, he might none the less be insane if he was caused to do the act by an irresistible impulse produced by disease. Counsel had to admit that English decisions do not go so far; but he urged that, since some earlier dicta suggested that such an additional rule might exist, this was a good opportunity for settling the point uniformly for the whole Empire. The Lord Chancellor, in dismissing the petition, answered that such a course would result in different standards being set up in England and the Dominions; the decisions of the Court of Criminal Appeal in England (e.g., *Rex v. Flavell* and *Rex v. Kopsch*) would remain unaltered. Lord Hailsham added a few words on the alleged misdirection at the trial with regard to onus of proof. The trial judge had apparently told the jury that the Crown had to prove its case beyond reasonable doubt, but that

the burden of proof in the case of insanity rested on the accused. *Sodeman's* counsel argued that the jury might have wrongly understood that the burden on the accused was as heavy as the burden on the Crown. Lord Hailsham observed that the burden of proving insanity on the part of the defence was not so onerous as the burden of proof resting on the Crown. It was no higher than the burden which rested on plaintiff or defendant in civil proceedings. The courts below were agreed that the language of the trial judge was not such as to be misunderstood by the jury or as to be capable of misleading them. The Judicial Committee would therefore not exercise the "very exceptional jurisdiction" reserved to it in criminal cases.

## IRELAND

(FROM OUR OWN CORRESPONDENT)

## A HOSPITALS ASSOCIATION FOR IRELAND

ON the occasion of the recent sweepstakes draw on behalf of the hospitals of the Irish Free State a meeting was held of representatives of nearly all the hospitals in the Irish Free State and some in Northern Ireland for the purpose of founding an Irish Hospitals Association. In the report of the Hospitals Commission attention was drawn to the need for such an organisation in order to encourage coöperation between the several hospitals. Dr. G. J. Moorhead presided at the meeting which was held at the Royal College of Surgeons on May 25th, and he consented to accept the presidency of the new association. The choice is a fortunate one, for to many years' experience as a hospital physician he is able to add a considerable experience as a hospital governor. Dr. J. P. Brennan was appointed honorary secretary, and a small provisional committee was appointed to frame a draft constitution and report to a second meeting of hospital representatives to be held in the autumn. It is intended that the membership of the association should be open both to institutions and to individual governors or members of medical staffs, and to rate-supported institutions as well as to voluntary hospitals. The provisional committee contains several public representatives as well as governors of voluntary hospitals and members of honorary staffs.

## THE CAMBRIDGE DIPLOMA IN RADIOLOGY

THE diploma in medical radiology and electrology is the only one granted in Cambridge that can be obtained by persons who have not resided or taken courses in the University. It was established in 1919 for a period of five years, and it has been prolonged from time to time on the ground that there was no other satisfactory alternative. It appears that 397 candidates have obtained the Cambridge diploma since its inception, while the total for all the other diplomas in medical radiology is less than 80, and the general board of the University are of the opinion that as long as this diploma is granted under the present conditions there is little likelihood of any other diploma in the subject becoming successfully established. In order that facilities for the lectures, practical instruction, and examinations may be provided elsewhere, they have decided not to continue the present arrangements indefinitely. Allowing enough time for plans to be made that will carry on the traditions and standards of the Cambridge diploma, the board have recommended that this shall no longer be given after October, 1941.

## PARLIAMENTARY INTELLIGENCE

### EDUCATION BILL: PROPOSED MEDICAL INSPECTION

In the House of Commons on May 26th, during consideration of the Education Bill on report, Mr. EDE moved an amendment to ensure that an employment certificate should be granted to the intended employer of a child if the issuing authority (the local education authority) were satisfied, after consultation with the local committee for juvenile employment, if any, and after consideration by the medical officer of the health and physical condition of the child, that the employment would be beneficial to the child. A similar amendment was, he said, inserted in committee of the Scottish Education Bill, making it a requirement that the consideration of the health and physical well-being of the child should be undertaken by the medical officer. If the clause were left as vague as it now stood, it would be possible for the consideration to be purely perfunctory. His amendment would ensure that expert evidence would be available for the committee advising the local authority.—Mr. COVE seconded the amendment.—Mr. OLIVER STANLEY, President of the Board of Education, said that he had every sympathy with the desire to see that the medical facts in each case were properly considered, but the amendment would give local authorities no powers that they did not already possess. Any authority could tell its medical officer exactly what part he had to take in the consideration of these exemptions. They had to assume that local authorities were anxious to carry out their duties properly. The school medical history, as it was now kept, after the recent Circular of the Board of Education with a view to co-operation with the Juvenile Employment Committee, would in the majority of cases give the local authority the information that it required. It contained specific reference to the suitability of a child for certain categories of employment, and a good many of the questions which the local authority might ask would be covered by the existing machinery. In any case, where there might be doubt, the school medical service was at the disposal of the authority, and he felt that the matter might be left there.—The amendment was negatived by 238 votes to 121.

Mr. MORGAN JONES moved an amendment limiting the hours of work of exempted children to not more than 40 a week, and providing that they should not be before 8 A.M. nor after 6 P.M. He said that the revelations of Sir John Orr had recently directed attention to the very serious condition of the children of the country, both in schools and elsewhere, and in particular to the physical condition of those children. For children of 14 to 15, eight o'clock was sufficiently early to be at work and six o'clock sufficiently late. How could young people avail themselves of opportunities for physical recreation unless their hours of work finished, at least, at six?—Sir PERCY HARRIS seconded the amendment.—Sir DONALD SOMERVELL, Attorney General, said it was open to a local authority to set a standard even higher than that set in the amendment, if it so desired, in the case of any particular child or group of children. On the other hand, it would be quite wrong, once the House had approved the principle of exemptions for beneficial employment, to introduce a rigid provision with regard to hours of work which would rule out of consideration certain employments which might well be beneficial, but in which the hours of work would be greater than 40 per week. The Government had promised to bring in during the next year, a Factory Bill, laying down the hours of work for children from 14 to 18, or whatever ages the House might decide. Local authorities might be trusted properly to administer the Bill. They were given a direct pointer by the House to consider hours of work as

one of the factors which must be taken into account. The Factory Bill would be the proper measure in which to consider hours of work. The Factory Bill would be discussed in the House before the present Bill came into operation.—Mr. R. J. TAYLOR said that the two-shift system was being worked in the North of England and the little boys would go to work in the mines till one or two o'clock in the morning.—The amendment was negatived by 220 votes to 126.

Mr. STANLEY secured agreement for an amendment to ensure that an employer should allow facilities to properly authorised officers of local education authorities to carry out inspections. This would enable the authority to satisfy itself that the employment had not, by reason of any change in the conditions of the employment or, for any other reasons, ceased to be beneficial to the child.

Mr. ORR-EWING moved an amendment to ensure that before granting a certificate exempting a child from school attendance for six months or longer, the issuing authority should require an undertaking from the parent or guardian of the child that a medical certificate would be produced reporting on the health of the child during the fourth month of employment. He said that the amendment supplied the means by which the local authority could ascertain whether the employment for the child had or had not been beneficial. A child who had received a certificate of exemption from school, and had gone into employment, might suffer a state of semi ill-health owing to the novelty of the situation having worn off by something like the fourth month, when the natural condition of the child would become apparent. If the employment was to last for a longer time than six months, which one might call the exempted period, the fourth month would be about the right time for the medical test to be made to ascertain if the child had suffered any ill-health because of the employment. He would have liked the child to be medically examined at school at the same time as the children who had not been exempted were being medically examined, so that some fair comparison could be made. Under the terms of the financial resolution that unfortunately could not be done. Anyone who had had experience of the employment of children in industry must be aware of many cases in which a normally healthy child had found its way into a type of employment which had affected either its body or its mind adversely. In such cases it would be greatly to the benefit of the child if it could be removed from that particular employment.—Lieut.-Commander AGNEW seconded the amendment.—Mr. STANLEY said that while he fully sympathised with the object of the amendment the method it proposed was unworkable. It put the obligation on the parent to get a certificate from the doctor, but they could not expect a parent, who would receive no reimbursement for his expenditure, to get a thorough examination of a child. The sort of certificate which the parent would obtain under such a system would hardly be worth the paper it was written on. He agreed that they ought to follow up these children, and not merely decide that the employment was suitable for their health at the beginning. He had already taken the proper step at the moment by inserting a provision in the undertaking to give access to any properly constituted authority for the purpose of inspection. They might, at a later stage, discuss with local authorities how an eye could be kept on the future health of these children and what steps could be taken if it became apparent that a particular job was proving detrimental to health. There was the further promise that the age of National Health Insurance would be lowered.—The amendment was by leave withdrawn.

On May 27th the Bill was read the third time.

## NOTES ON CURRENT TOPICS

## Adjournment for Whitsuntide

BOTH Houses of Parliament adjourned on Friday, May 29th, for the Whitsuntide recess. The House of Lords will reassemble on June 11th and the House of Commons on June 9th.

## Vivisection of Dogs

In the House of Commons on May 28th Mr. RADFORD presented a petition signed by more than 6000 citizens of Manchester praying the House to pass a Bill to prohibit the vivisection of dogs.

## Bronchitis and Tuberculosis in Wales

In reply to questions put to him by Mr. JAMES GRIFFITHS, the Minister of Health gave the mortality-rates from bronchitis and tuberculosis in the year 1935 in certain administrative counties of Wales, along with comparative rates for England and Wales.—The following is the answer:—

BRONCHITIS, 1935		TUBERCULOSIS (ALL FORMS), 1935	
Mortality (provisional) per million living			
England and Wales ..	388	England and Wales ..	718
Carmarthen .. ..	362	Carmarthen .. ..	955
Glamorgan .. ..	577	Pembroke .. ..	1022
Monmouth .. ..	498	Glamorgan .. ..	893
Brecknock .. ..	397	Monmouth .. ..	825
		Brecknock .. ..	812
		Cardigan .. ..	1283

## Family Budgets

In the House of Commons on May 28th Mr. ASTOR asked the Minister of Labour whether he was now in a position to state the names of the members of the committee which was to advise on the methods to be adopted in the collection by means of family budgets of information as to working-class expenditure.—In reply Mr. E. BROWN stated that the following have been appointed to be a committee to advise the Minister of Labour as to the methods to be adopted in the collection of information by means of family budgets, showing the approximate average weekly expenditure of working-class families on the items which should be taken into account in the construction of index numbers, designed to measure the percentage changes from month to month in the cost of maintaining a present-day standard of living:—

Mr. F. W. Leggett, C.B., Principal Assistant Secretary, Ministry of Labour (chairman); Mr. J. N. Beckett, Assistant Secretary, Ministry of Health; Mr. F. J. Blake, O.B.E., J.P., Past President of the National Chamber of Trade; Prof. A. L. Bowley, Sc.D., F.B.A., Professor of Statistics, University of London; Mr. H. Crow, O.B.E., Principal, Scottish Office; Mrs. W. Y. Darling, wife of Councillor W. Y. Darling, Edinburgh; Mrs. C. S. Ganley, J.P., L.C.C., a member of the Management Committee of the London Co-operative Society; Mr. J. Hallsworth, representing the Trades Union Congress General Council; Dr. J. M. Hamill, O.B.E., M.D., D.Sc., Senior Medical Officer, Ministry of Health; Mr. C. T. Houghton, Assistant Secretary, Minister of Agriculture and Fisheries; Mr. W. A. B. Iliff, M.B.E., Assistant Secretary, Ministry of Labour, Northern Ireland; Mr. D. Caradog Jones, M.A., Lecturer in Social Statistics, University of Liverpool, and Director of the Social Survey of Merseyside; Mr. Kenelm Kerr, O.B.E., representing the National Confederation of Employers' Organisations; Mr. E. C. Ramsbottom, O.B.E., Director of Statistics, Ministry of Labour. The Secretary to the Committee would be Mr. J. G. Cannell, Ministry of Labour, Queen Anne's Chambers, Broadway, Westminster, S.W.1.

## HOUSE OF COMMONS

WEDNESDAY, MAY 27TH

## Food-supply in War Time

Captain GUNSTON asked the Minister for the Coördination of Defence how the problem of food-supply in time

of war was to be divided between the subcommittee of the Committee of Imperial Defence and Sir William Beveridge's subcommittee.—Sir T. INSKIP replied: The subcommittee which has been appointed under my chairmanship is examining all aspects of our food-supply in time of emergency. They include, for example, home production, the protection of shipping, security in ports, distribution and transport questions, and reserve stocks. The reference to Sir William Beveridge's subcommittee is limited at the present stage to the consideration of arrangements for rationing the supply to the individual consumer in case of necessity, and of the preparatory steps which might be taken to enable such arrangements to be brought into force as quickly as possible.

## Decline in Milk Consumption

Mr. ALEXANDER asked the Minister of Agriculture whether he was aware of the decline in the consumption of liquid milk in three out of the four months of 1936 for which figures were available, and that, but for the fact that there were 29 days in February this year, the figures for the complete four months would show a heavy decline in liquid consumption for milk compared to 1935; and to what extent this decline was due to the higher retail prices for milk on account of the successive increases in contract prices.—Mr. RAMSBOTHAM, Parliamentary Secretary to the Ministry of Agriculture, replied: After making allowance for the extra day in February this year, sales of milk by wholesale for liquid consumption in the first four months of 1936 show a decline of approximately one million gallons, or about half of one per cent. compared with the corresponding period in 1935. As to the last part of the question, the minimum appropriate retail prices were the same this year as last.

## Drug Addicts

Mr. ARTHUR HENDERSON asked the Home Secretary whether his attention had been called to the report of the opium section of the League of Nations, stating that there were 30,000 confirmed drug addicts in this country; and whether he could make a statement on the matter.—Mr. GEOFFREY LLOYD, Under-Secretary, Home Office, replied: My right hon. friend's attention has been drawn to a statement in the press that there are 30,000 drug addicts in this country. This statement is wholly unfounded. It purports to be based on a report of the opium section of the League of Nations Secretariat, but I am informed that this report contained no such statement. I may add that, according to the information available in the Home Office, the number of addicts known to the authorities does not exceed 700.

Mr. HENDERSON: Could the hon. gentleman give the House any information as to whether the traffic is on the increase or otherwise?

Mr. LLOYD: Our information is that such traffic in this country is very small indeed, and in any case is confined to London; and even there it is very small.

## Cancer Mortality

Mr. LAMBERT asked the Minister of Health the average mortality from cancer for each decennial period since 1850, and the mortality for the last five available years respectively.—Sir KINGSLEY WOOD replied: The standardised mortality-rates per million persons in England and Wales from cancer for the periods specified in the question are as follows:—

Year.	Mortality-rates per million.	Year.	Mortality-rates per million.
1851-60 .. ..	326	1921-30 .. ..	991
1861-70 .. ..	396	1930 .. ..	1003
1871-80 .. ..	484	1931 .. ..	998
1881-90 .. ..	610	1932 .. ..	1001
1891-1900 .. ..	767	1933 .. ..	997
1901-10 .. ..	867	1934 .. ..	1003
1911-20 .. ..	928		

THURSDAY, MAY 28TH

## Diphtheria Immunisation

Mr. SEXTON asked the Minister of Health whether he was satisfied that inoculation against diphtheria was such a proved success as to warrant advising compulsory

use.—Sir KINGSLEY WOOD replied: I am satisfied that artificial immunisation against diphtheria is based on sound scientific principles, and has proved of value, but I should not be prepared to advise that its use should be made compulsory.

#### Health Conditions in Schools

Viscountess ASTOR asked the President of the Board of Education, in view of the importance of the welfare of school-children of school premises having good ventilation, heating, water-supply, sanitation, and playgrounds, he would cause a survey to be made of all school premises in county areas, in order to furnish information as to the number of school premises, provided and non-provided, respectively, in which unsatisfactory conditions obtained in any or all of the following respects: supply of water for drinking or for lavatory purposes; sanitary arrangements and cloakrooms; lighting, natural and artificial; ventilation; playgrounds; and damp walls and other structural disrepair.—Mr. OLIVER STANLEY replied: The development of reorganisation, to which the Board have called attention in Circular 1444, will during the next two years necessitate a survey of school premises from the point of view of the part which they are to play in the schemes for their districts. A survey of this nature will, I hope, achieve all the results the noble lady has in mind.

#### Puerperal Fever: Quarantine of Midwives

Mr. SEXTON asked the Minister of Health whether he was satisfied that the period of quarantine enforced on a midwife after attending a case of puerperal fever was long enough to ensure safety in attending succeeding cases.—Sir KINGSLEY WOOD replied: The period of suspension in these cases is that laid down in the rules made by the Central Midwives Board, and I have no reason to suppose that it is insufficient.

#### Rehousing Accommodation

Mr. DAVID ADAMS asked the Minister of Health whether he proposed to issue a publication, with typical plans of large houses containing four and five bedrooms, for the assistance of local authorities in connexion with their statutory duty to provide suitable alternative accommodation under the terms of the Housing Act, 1935, for large families at present living under overcrowded conditions.—Sir KINGSLEY WOOD replied: The question raised by the hon. Member is at present under consideration. In the meantime, my department have type plans of large houses which are available for the guidance of local authorities.

#### Mental Hospital, Barnsley: Maintenance Charges

Mr. PORTS asked the Minister of Health the statutory authority under which the Barnsley magistrates had recently made an order requiring a man to contribute towards the support of his married daughter who happened to be an inmate of a mental institution, and who was also supported by her husband.—Sir KINGSLEY WOOD replied: I presume that the magistrates' order was made under the authority of Section 19 (2) of the Poor Law Act, 1930. That subsection enables public assistance authorities to obtain, on complaint to a petty sessional court, orders of maintenance upon the relations liable to maintain a poor person, and the father is included, by Section 14 of the Act, among the relations so liable.

#### The League and Red Cross Organisations

Mr. MANDER asked the Secretary of State for Foreign Affairs, in view of the fact that the members of the International Red Cross committee were entirely of Swiss nationality, he would ask the council of the League of Nations to discuss how far it was desirable for the League to recognise as genuinely international a body so constituted, having particular regard to Article 25 of the Covenant, under which reference was made to the League's relations with the Red Cross organisations.—Viscount CRANBORNE, Under-Secretary for Foreign Affairs, replied: While my information is that the hon. Member is correct

in stating that the International Red Cross Committee is entirely composed of Swiss citizens, I understand that the status and functions of that body, as defined in Article 7 of the statutes of the International Red Cross organisation, make it clear that it is an independent institution having its own statute and particular functions. This position is no doubt well recognised by other members of the League, and I do not therefore think that action by H.M. Government such as is suggested is required.

#### Prison Warder and Blood Transfusion

Mr. THURTLÉ asked the Home Secretary whether he was now in a position to say anything regarding the case of Warder J. Jelly, of Wandsworth prison.—Sir J. SIMON replied: On the morning of a day on which this officer was due to perform duty as a trade instructor he stated that he had undertaken to attend at St. James's Hospital to give a blood transfusion and applied for leave to be absent from duty from 11 to 12 for this purpose. His application was made without previous warning, and as the absence without notice of an officer detailed for essential duties seriously disorganises the arrangements for the custody and employment of prisoners, he was told that he was not entitled to commit himself to an engagement during his hours of duty. The governor explained the position to the hospital authorities by telephone, and on learning that it would be difficult to obtain a substitute at short notice the governor agreed, as an exceptional case, to allow Officer Jelly to absent himself from duty in order to attend at the hour named. The officer, on being so informed, then refused to go, but I understand he subsequently attended the hospital during the dinner hour. On the following day he addressed to the Prison Commissioners a letter of protest couched in such terms that they could only regard it as insubordinate and as indicating that the officer did not appreciate his special responsibilities as trade instructor. In view of the terms of this letter the Commissioners decided that he should no longer be employed as trade instructor, but should revert to discipline duty. The officer has since been interviewed at his own request by a Commissioner and an Assistant Commissioner of prisons; but after reviewing the matter in the light of his representations the Commissioners have found no reason to modify their original decision.

#### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED  
MAY 23RD, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1868; diphtheria, 920; enteric fever, 36; pneumonia (primary or influenzal), 909; puerperal fever, 39; puerperal pyrexia, 129; cerebro-spinal fever, 22; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 2; dysentery, 16; ophthalmia neonatorum, 100. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 29th was 5344, which included: Scarlet fever, 1055; diphtheria, 1251; measles, 1738; whooping-cough, 611; puerperal fever, 21 mothers (plus 13 babies); encephalitis lethargica, 285; poliomyelitis, 1. At St. Margaret's Hospital there were 30 babies (plus 13 mothers) with ophthalmia neonatorum.

*Deaths.*—In 122 great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 48 (23) from measles, 3 (1) from scarlet fever, 32 (11) from whooping-cough, 25 (0) from diphtheria, 46 (17) from diarrhoea and enteritis under two years, and 40 (8) from influenza. The figures in parentheses are those for London itself.

No great town reported more than 2 deaths from measles. There were 7 deaths from whooping-cough at Liverpool, 3 at Birmingham. Deaths from diphtheria were reported from 20 great towns, not more than 2 from any. The only fatal case of typhoid was at Cardiff.

The number of stillbirths notified during the week was 291 (corresponding to a rate of 42 per 1000 total births), including 42 in London.

## OBITUARY

**THOMAS ARTHUR HUGHES, M.D., Sc.D. Dub.,  
F.R.C.P. Lond.,  
LIEUT.-COLONEL, I.M.S.**

Colonel Hughes's many friends in India and this country will have read with deep regret the announcement of his death at an English sanatorium on May 23rd. He had been in poor health for the past few years but had refused to give up his work until it became physically impossible for him to carry on any longer. Owing to a severe exacerbation of his lung trouble he was compelled to take leave about two months ago.

Thomas Arthur Hughes was born in 1884 in Co. Armagh, a son of the late Mr. P. Hughes. He was educated at Blackrock School and Trinity College, Dublin, where he won many prizes, and on qualifying M.B., B.Ch. in 1909 he became assistant in the physiological department. He entered the Indian Medical Service in July, 1910, and took the D.P.H. in the following year. Three years later he became captain and acted as medical officer of the 24th Punjabis, gaining the experience which led him to write on the nature of pulmonary tuberculosis and of cirrhosis of the liver as seen in the Punjab. He served in the European War of 1914-18, and in 1920 he was appointed to the chair of physiology at King Edward Medical College, Lahore, and four years later professor of clinical medicine and medical superintendent of the Mayo Hospital. Shortly before he left India he was appointed to the post of principal and professor of medicine.

Sir John Megaw writes: "Although Hughes had a very high reputation as a physician, his leanings were chiefly towards medical research and he made valuable contributions to the *Indian Journal of Medical Research* on pulmonary tuberculosis in adult punjabis as well as on cirrhosis of the liver and diseases of the heart. He was a man of attractive personality and high ideals. He neglected opportunities of making money by private practice but never spared himself when attending to his hospital patients, teaching his students, or carrying out a piece of research. His premature death was undoubtedly due to his high sense of duty."

Colonel Hughes leaves a widow, who was with him throughout his illness, and two children—a boy of 10 and a girl of 5.

**JOHN THOMAS HEWETSON, M.D. Edin.,  
F.R.C.S. Eng., F.C.O.G.**

Dr. Hewetson, whose death took place on May 19th, was born at Hornsby Gate, near Carlisle, in 1872, and educated at Edinburgh University and London, taking the degree of M.B. at Edinburgh, and subsequently becoming M.D., F.R.C.S., and F.C.O.G. He commenced his private practice in Coventry, but did not remain long in general practice, and whilst still resident in Coventry he commenced research work at the General Hospital, Birmingham. He was a man of outstanding ability and came under the eye of Sir Gilbert Barling, who invited him to become his assistant, and thus started for him what was a fine experience in general surgery before he specialised in the branch of surgery to which he later devoted his life. He was appointed assistant obstetric officer at the General Hospital in April, 1903, and held the appointment for five years until he resigned in 1908. In 1907 he joined the honorary staff of the Maternity Hospital and in 1908 he accepted a similar appointment at the Women's hospital at

Sparkhill. From 1933 to the time of his death he was chairman of the Medical Board at the Women's hospital and senior surgeon.

A colleague writes: "A great surgeon and a master of his art, cool-headed, he was able to exercise remarkable self-control and was never ruffled in the operating theatre, where he treated everyone with courtesy, tact, and consideration. These qualities, allied to his personal charm, endeared him to all with whom he came in contact. His hospital work was always his first consideration and he never allowed his remunerative practice to interfere with the very extensive amount of work he did in an honorary capacity at the hospitals. He was beloved by all, particularly those best able to see and appreciate his great services to humanity. Although he did a colossal amount of work, his organisation was such that he was invariably on time for all his appointments—a rare quality in one so fully occupied.

"He was a great lover of sport, particularly football and cricket, and a practical supporter. He was a member of the Committee of the Warwickshire County Cricket Club from 1922 to 1926, from which latter date he has been a vice-president of the club."

**FREDERICK DENYS CREW, M.B. Camb.**

Dr. Frederick Crew, who died on May 25th, succeeded his father Dr. John Crew in practice at Higham Ferrers some 20 years ago, the family connexion with the practice being therefore a very long one. He was educated at Felsted, proceeded to Cambridge, and received his medical education at Guy's Hospital, where he graduated in 1906; shortly afterwards he went into partnership with his father, whom later he succeeded as medical officer for the borough of Higham Ferrers. During the war as an officer in the R.A.M.C. he served for a year in Mesopotamia, and he took a close interest in ambulance work, lecturing for the St. John Ambulance Association. He was only 57 years at the time of his death, which followed a short illness. He leaves a widow and two sons.

**THE LATE PROF. FRIEDRICH KRAUS**

EIGHT years ago when Friedrich Kraus reached his seventieth birthday the German medical press contained graphic sketches of a man who was recognised by his colleagues everywhere as the outstanding medical genius of his time. One of these<sup>1</sup> was from the pen of Prof. G. v. Bergmann. His recent death has brought us the following appreciation from Prof. J. Plesch, another of his co-workers.

"I see him," Prof. Plesch writes, "his enormous head with its clever forehead covered by a crumpled felt hat, a smile irradiating the whole of the broad reddish face, his long beard roving over his large paunch, his square stumpy-fingered hands, like those of the most productive thinkers—standing at the door of the Charité, when he was called in 1903 to the directorship of the foremost clinic in Germany. . . He irradiated a natural dignity which was entirely lacking in sternness, and nothing but goodwill beamed from his little pig-like eyes. He was an amiable conversationalist, interested in everything with an unlimited scope due to comprehensive knowledge. Yet he had a receptive talent, but not of that sponge-like variety which absorbs ideas only to return them, when pressed, practically unchanged. His mind was receptive to everything, and he received and absorbed information and ideas in such a way that when he

<sup>1</sup> Deut. med. Woch., 1923, liv., 859.

reproduced them his brain had moulded them into forms so different that they hardly showed a trace of their origin. His mind was in fact synthetic rather than analytic. Such was Friedrich Kraus as I knew him.

"Kraus was born in Austria at Bodenbach in 1858—the best vintage year of German clinicians, for it produced not only Kraus, but Krehl, Müller, and von Noorden. His father was a poor pensioner who died of a progressive paralysis; in spite of this handicap, throughout his long life Kraus was nevertheless physically and psychically unaffected. He presented himself to the world in a 'breech posture,' and used to say that he had maintained this attitude consistently throughout his life. His students days were spent at the University of Prague, where he lived in the hospital whose damp walls are responsible for the polyarthritis which he developed in his hands and feet while still in early youth. He never lost this deformity which so impaired his dexterity that he could hardly percuss.

"Thanks to his early studies in biochemistry and physiological anatomy at Prague, Kraus was well prepared to enter the clinic of Kahler, who later became a neurologist and, working with Charcot in Paris, in due course summoned Kraus to be his assistant. At this time Kraus's clinical knowledge was not great, but Kahler personally directed his early and necessarily simple clinical investigations. Two years later Kahler obtained a professorship in Vienna and took Kraus with him. In less than a year, however, Kahler died of cancer of the tongue, and at the early age of 28 Kraus had to take over his clinical teaching work. In spite of his youth he was considered as a possible successor to the chair of Skoda and Bamberger in Vienna. Though he was unsuccessful in the competition, it was a compensation to become chief physician in the famous Rudolf Hospital, where he remained for five years until he was promoted to a chair at the University of Graz, which he held until 1903. On the death of Karl Gerhardt in Berlin, Althoff—that reformer of the German universities—took the bold step of including after the names of L. Krehl and F. Müller that of the still young Kraus as one of the nominees for the vacant chair. Kraus was appointed, and continued his work as a leading teacher and professor of the German physicians until 1929, when he became emeritus. He was, for about fifteen years, chairman of the Berlin Medical Society, and his good-natured, pointed, and spirited comments were always eagerly awaited at the meetings. Empiricism had little place in the scientific method by which he built up his clinic. His attitude was experimental, and therefore largely based on positive facts. He was vividly interested in every new method and system that developed during this period when thought and methods in medicine, as in all the sciences, were undergoing far-reaching changes.

"Kraus was not one of those clinicians who, in the minds of his successors, would remain associated with one specific idea or method. This did not and does not mean that he was ever unstable, unsound, or incapable of making a deep impression upon his pupils and collaborators. On the contrary his spirit and his attitude of mind will long remain effective in medicine through the thousands of those who were privileged to work with him and under his tutelage. He did much pioneer work and carried out many new investigations which heightened the reputation of the clinic. Immediately upon their discovery he realised the great possibilities which lay in the medical use of X rays, and his clinic was the first in the world to have a fully equipped X ray laboratory attached to it. From this it naturally followed that his pupils were amongst the first to carry out important radiological investigations. Kraus also early introduced Einthoven's electrocardiograph into his clinic, and with his pupils he explored the new field of knowledge which this opened up. Such men as Schaudinn, Wassermann, and Ehrlich were delighted to come to his clinic; Pappenheim developed

here the hæmatology of Ehrlich, and, when psychoanalysis had not even aroused its earliest antagonisms, Kraus made Freud and Jung welcome. Many celebrated biochemists worked in his laboratory: it was Kraus who early recognised the great clinical importance of Haldane's and Zunz's work on gas-metabolism, and he was the first clinician to use their methods, in the work by which he is best known, 'Fatigue as a Measure of the Constitution.' It may truly be said that under the guidance of this master some of the most important devices in many branches of medicine as we know it to-day made their earliest and perhaps most significant progress.

"It is almost impossible adequately to record the full tale of the many different activities which were influenced by his spirit during his fifty years as teacher and research worker. However, when it is remembered that the true scientific development of modern medical knowledge took place in his lifetime, and that he was alive to and interested in all that was going on around him, it is more possible to form a general idea of the immensity of his brain, and the greatness of his achievement. It is then not surprising that he never became one-sided in spite of the intensive character of his medical knowledge. With the development of his clinic and the increasing sphere of his influence, he became as it were a stronger and stronger focus which collected rays emanating from each and every source. It was only natural for such a man to turn from the pathological, anatomical, morphological, and topical mode of thought to the physiological-pathological, to the functional diagnosis. At the end of his life he gave us a sublimation of his thought, which was at the same time his apologia, in his 'Syzygiology, the Pathology of the Person,' containing ideas which have influenced and directed medical thought in the past and will do so in the future.

"Except for the arthritis already referred to, he was never really ill in his life, although he never took a holiday—not even a Sunday; neither did he take any exercise—not even so much as a daily walk. His whole life was devoted to his professional duties and to medical research, until at last he had the misfortune to break his leg, became decubital, and died of sepsis. He was not only a great teacher, he was also a great doctor, and not the least factor in making him so was the nobility of his character. His personality in the sick-room had a tonic effect, and gave him an enormous psychological influence over the patient. He was the most consulted physician of his time on the continent of Europe, but he treated 'the prince as a peasant, and the peasant as a prince.' His manner was gentle and modest, but nothing could equal his pride when, as the representative of professional knowledge, he spoke ex cathedra. His pupils are to be found all over the world to-day, among them being many British doctors who came to sit at his feet in Berlin."

**JOINT TUBERCULOSIS COUNCIL: REPORTS OF COMMITTEES.**—At a recent meeting of this council a report of the pneumothorax committee was discussed and adopted for presentation to the Medical Research Council. The committee agreed to report again on the extended reference: "To investigate and report on the results of artificial pneumothorax and how these may be improved." Dr. C. O. Hawthorne made a verbal report on behalf of the milk committee. The new order on milk designation, coming into force on June 1st, recognised tuberculin-tested milk and pasteurised milk. The other grade was accredited milk, or Grade A under another name; "the name," he said, "continues to reassure the public, although by no admitted standard can milk so labelled be regarded as safe." A recent inquiry by the People's League of Health had shown that, while to the majority of children in elementary schools pasteurised milk was being supplied, a substantial minority was receiving unprotected milk—i.e., raw milk of Grade A. Hence the continuing need for educational efforts to enable the public to distinguish between safe milk and milk which claimed merely to be clean.

## CORRESPONDENCE

## "ALLEGED DYE DERMATITIS"

To the Editor of THE LANCET

SIR,—I have received a pamphlet through the post entitled Interim Report on Alleged Dye Dermatitis Position. It relates that a committee representing colour makers and users has met ten times and collected a large amount of information and has decided to try and find a case which would enable them to obtain a Court of Appeal decision on idiosyncrasy not being included in the term "reasonably fit" of the Sales and Goods Act, 1893. It has been estimated this would cost £3000, which it is proposed to spread over the dye using and making interests. Three dermatologists, one in London, one in Leeds, and one in Manchester, have been "recommended" by this committee. It is also reported that "it has also been suggested that one firm of solicitors should be appointed to handle all cases, but this suggestion is strongly objected to in many quarters." The Alleged Dye Dermatitis Committee should, they say, be given authority and financial backing to fight any suitable case which is reported to it, and it should endeavour to get its point of view distributed to the professions by means of journals such as *The Lancet* and the *Analyst*.

It is a little difficult to appreciate this communication at its full value. I conceive it possible that dermatologists apparently committed in advance to a fixed outlook on "alleged dye dermatitis" would find difficulty in convincing a court of their entire freedom from bias in their approach to any case. My three colleagues will no doubt share my regret that the distribution of the £3000 is not to fall with impartiality upon all practising dermatologists. I am sure they themselves are not party to the suggestion that their other colleagues are less wide awake to the problems of idiosyncrasy. I would not suggest their cognisance of this pamphlet. It is well that skin specialists who are in a position to sign certificates of dye dermatitis should know what they may be up against. I have no doubt they will, as in the past, deal with each case on its merits according to their knowledge and experience.

It is stimulating to know that any one of us in practice may, without prevision, sign the test certificate on which will rest the case on which the Court of Appeal may hear our cross-examination on idiosyncrasy in all its bearings.

I am, Sir, yours faithfully,

Harley-street, W., May 29th. W. J. O'DONOVAN.

## AIR MINISTRY AND VENEREAL DISEASE

To the Editor of THE LANCET

SIR,—In these days, when a large reserve of civilian pilots is desirable, everything possible should be done to encourage young men to take out flying certificates and to renew their private pilot's licence. Yet heading 6 (b) of the Air Ministry's medical renewal examination (C.A. Form 61) puts the question: "Has suffered from venereal disease?" Now, as a venereologist, I have had several patients who very greatly object to this question. They express the opinion, which I think is sound, that if since the last medical examination for their flying licence they have contracted venereal disease and have completely recovered, so that no clinical or pathological signs of infection remain, they should not be required to put on record that they have had venereal disease. This question has prevented more than one young

man from renewing his licence. During 1917, when at home after becoming a casualty, I was in charge of an officers' V.D. hospital. Nearly three-quarters of my patients were officers of the Royal Flying Corps and several were most distinguished officers of that most distinguished corps—Mars and Venus were ever closely associated. As soon as clinical symptoms and often (in the case of syphilis) before pathological symptoms had cleared up they were returned to their squadrons. In my opinion question 6 (b) is unnecessary and should be deleted.

I am, Sir, yours faithfully,

H. WANSEY BAYLY.

Late acting Lt.-Col., R.A.M.C.(T).  
Harley-street, W., May 29th.

## PROGRESS IN RADIOTHERAPY

To the Editor of THE LANCET

SIR,—On page 1228 of your last issue Dr. Schiller, referring to the radiological treatment of carcinoma of the cervix, says "Improvement in X ray or radium therapy is not possible with ordinary apparatus, which to-day is at its maximum efficiency. An improvement of radiotherapy might be obtained only by applying stronger or more efficient rays." It is, perhaps, worth while mentioning that advances in radiological treatment are more dependent upon the ideas and methods of radiologists than they are upon the mechanical efficiency of any apparatus. One would have liked to think that the conception, that only by applying stronger radiation would better results be obtained, was relegated to the past. Does Dr. Schiller think that the fundamental observations gleaned during the last few years at the Strangeways Laboratory on "optimum intensities" have no bearing on future practice, or that the search for methods of rendering tumours more sensitive to radiation is not as much warranted as indulgence in stronger and stronger radiation?

I am, Sir, yours faithfully,

Barnato Joel Laboratories, May 29th. SIDNEY RUSS.

## BADGES FOR DOCTORS' CARS

To the Editor of THE LANCET

SIR,—During last month the secretary of the National Motorists Association, Mr. Charlton Elliott, addressed a circular letter to the medical profession on the subject of a special badge to be affixed to the motor cars of doctors. That letter contains a paragraph purporting to describe an interview with me, which I quote below:—

"Dr. Anderson, Secretary to the B.M.A., agreed with the Association's suggestion that, if it is found that the scheme is working satisfactorily on these lines, they would be pleased to consider giving official recognition at a later date, but they would, for the present, have to confirm in the *Medical Journal* the stand they had adopted in the past when this question had been put forward by medical men themselves, many of whom will have noted that THE LANCET, the same week, announced their approval of the scheme."

This is an entirely inaccurate account of what took place. In March last a statement appeared in a Sunday newspaper that a circular dealing with the issue of Red Cross motor car signs to doctors "will be issued through the British Medical Association." Exception was taken by me to this misleading statement, and in response to my protest the acting editor informed me that the statement was made on the authority of Mr. Charlton Elliott. Mr. Elliott subsequently came to see me on March 19th, and I

interviewed him in the presence of the Deputy Medical Secretary. At this interview it was made plain to Mr. Elliott that the British Medical Association had, after careful consideration, rejected the proposal that special badges should be supplied or approved for use on doctors' motor cars. Indeed, Mr. Elliott stated that if the British Medical Association was unfavourable to such a proposal it would be dropped. This represents the full substance of the interview, and the suggestion in Mr. Elliott's letter that I indicated that approval might be regarded as merely delayed is completely unfounded.

On April 4th Mr. Elliott sent me a copy of the badge which it was proposed to issue to doctors. In reply I wrote as follows:—

"I have no observations to make upon the design. As I explained at our interview the medical profession has no desire to have a special badge for doctors' motor cars."

This letter eliminates any possibility of misunderstanding as to the attitude of the British Medical Association, and I accordingly deemed it my duty to publish the true facts lest members of the medical profession should be misled by this circular letter.

I am, Sir, yours faithfully,

G. C. ANDERSON,  
Medical Secretary, B.M.A.

B.M.A. House, Tavistock-square, W.C., June 3rd.

## FOTHERGILL TESTIMONIAL FUND

THE following is the sixth list of subscribers to the testimonial to Dr. E. Rowland Fothergill received in response to the letter published in the *British Medical Journal* and *The Lancet* of Jan. 18th.

Amount previously acknowledged, £1466 17s.  
Wiltshire Panel Committee, £25; S. D. Bhabba (London), £1; Reading Panel Committee, £5 5s.; Stoke-on-Trent Panel Committee, £10 10s.; H. C. Bristowe (Bristol), £1 1s.; Wakefield Panel Committee, £2 2s.; H. Newsome (near Bristol), 5s.; N. Flower (Yeovil), 10s. 6d.; R. St. J. Kemm (Cheddar), 10s.; Drs. Cameron, Collins, and Pearce (Taunton), £1 1s.; J. Evans (Knowle), 5s.; E. B. Hinde (Norwich), £1 1s.; Annie Hyatt (Shepton Mallett), 5s.; East Riding of Yorkshire Panel Committee, £10 10s.; H. R. Unwin (Yeovil), J. E. Seales (Radstock), and B. A. Crook (Tisbury), each 5s.; Brighton Public Medical Service, £10 10s.; K. J. Atkinson (Halstead), 5s.; W. A. Gornall (Nailsea), £1 1s.; E. M. Redman (Bristol) and J. M. Dupont (Frome), each 5s.; Doncaster Local Medical and Panel Committee, £1 1s.; Smethwick Medical Society, £3 3s.; E. G. D. Pineo (Langford), 5s.; Rochdale Panel Committee, £10; Sheffield Panel Committee, £40; Croydon Panel Committee, £5 5s.; East Ham Panel Committee, £8 6s. 6d.; Warrington Local Medical and Panel Committee and Southend Local Medical and Panel Committee, each £5 5s.; G. Pollock (London), 10s. 6d. Total £1619 16s.

In accordance with the decision conveyed in the previous announcement the Fund has now been closed.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. J. C. Souter to *President* for Medical Dept., Admiralty.

Surg. Lt. J. Lees to *Effingham*.

A. G. K. Heberlein entered as Surg. Lt. (D) for short service and appt. to *Victory* for R.N. Hospl., Haslar, for course of instruction.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Comdr. R. Hall to *Royal Sovereign*.

Surg. Lts. to be Surg. Lt.-Comdrs: R. Cormack and M. Godwin.

### ARMY MEDICAL SERVICES

Cols. N. E. Dunkerton, D.S.O., late R.A.M.C., and P. J. Hanafin, D.S.O., late R.A.M.C., retire on ret. pay.

Lt.-Cols. J. E. Ellcome, from R.A.M.C., and H. H. Blake, O.B.E., from R.A.M.C., to be Cols.

### ROYAL ARMY MEDICAL CORPS

Majs. E. F. W. Grellier and G. D. Jameson to be Lt.-Cols. Short Service Commissions: Lts. (on prob.) restd. to the estab.: D. Wright, and C. P. Stevens; Lts. (on prob.) confirmed in their rank: J. McN. Lockie, and J. H. Caverhill; Lt. (on prob.) F. J. Hebb resigns his commission.

### ROYAL AIR FORCE

Wing Comdr. A. F. Rook to Central Medical Establishment, London, for duty as consultant in medicine.

Squadron Leaders J. Magner to R.A.F. Hospital, Cranwell, for duty as medical officer; R. G. Freeman to R.A.F. Depôt, Uxbridge, for duty as medical officer.

The undermentioned are granted short service commissions as Flying Offrs. and to Medical Training Depôt, Halton: J. R. R. Jenkins, V. D. Jones, R. M. Outfin, J. H. Neal, R. H. Pratt, D. G. Smith, S. G. Gordon, J. C. Bowe, G. P. Jones, and J. G. Rountree.

Flying Offr. F. Courtin ceases to be seconded to the Royal Victoria and West Hants Hospital.

### DEATHS IN THE SERVICES

Lt.-Col. WILLIAM CAMPBELL, who died on May 24th at Walton-on-the-Hill in his 86th year, was born in Edinburgh, where he obtained his medical degree in 1872. He took a commission in the Army in September, 1874, and was surgeon to the Scots Guards in 1881 and surgeon major to the Grenadier Guards in November, 1887, reaching the rank of surgeon Lt.-col. in 1894. He served in Egypt in 1882 and retired in June, 1897.

## Appointments

EVANS, K. A., L.R.C.P. Irel., has been appointed First Assistant Resident Medical Officer at Birch Hill Hospital, Rochdale, and Medical Officer in Charge of Antenatal and Postnatal Clinics.

GAVIN, F. W., M.D. Edin, D.P.H., Medical Officer for Penrith Urban and Rural areas.

HARRISON, J. G., L.R.C.P. Edin., Senior Resident Medical Officer at the City Hospital, Chester.

MOODIE, WILLIAM, M.D. St. And., F.R.C.P. Lond., D.P.M., Assistant Physician in the Department of Psychological Disorders in Children at University College Hospital.

London Homœopathic Hospital.—The following appointments are announced:—

HUGHES, D. M., M.B., F.R.C.S., Hon. Consulting Surgeon;

BARRY, GERALDINE, M.S. Lond., F.R.C.S. Eng., Hon. Surgeon; and

DODD, HAROLD, Ch.M. Liverp., F.R.C.S. Eng., Hon. Assistant Surgeon.

## Births, Marriages, and Deaths

### BIRTHS

BUTLER.—On May 24th, at Sutherland-avenue, W., the wife of Dr. Eric N. Butler, of a son.

DAY.—On May 22nd, at Chapel Field East, Norwich, the wife of Dr. George Day, of a son.

HOSFORD.—On May 27th, at Stormont-road, Highgate, the wife of R. W. P. Hosford, F.R.C.S. Eng., of a daughter.

JAQUES.—On May 24th, at Burnham, Buckinghamshire, the wife of Harold M. Jaques, M.R.C.S. Eng., of a son.

MCKINSTRY.—On May 23rd, at Gunterstone-road, W., the wife of Dr. W. K. McKinstry, of a daughter.

MOWAT.—On May 24th, at Kampala, Uganda, the wife of Allan Mowat, F.R.C.S. Edin., of a daughter.

TANNER.—On May 30th, at Newton Abbot, the wife of Guy M. Tanner, M.B. Camb., of a son.

WORTHINGTON.—On May 22nd, at Warwick, the wife of Dr. C. L. Worthington, of a daughter.

### MARRIAGES

SLOT—LEWIS.—On May 29th, Gerald Slot, M.D. Lond., to Mary Lewis, of 2 Wellington House, Regent's Park, N.W., daughter of the late Mr. and Mrs. J. A. Munton, of Idle, Yorkshire.

### DEATHS

BOLUS.—On May 26th, suddenly, at Queensberry House, Richmond, Surrey, Harry Boulcott Bolus, M.D. Camb., aged 68.

CAVERS.—On May 26th, Francis Cavers, D.Sc. Lond., M.R.C.S. Eng., of Knobworth, Herts.

CRAIK.—On May 23rd, at St. Albans-road, Watford, John George Craik, M.B. Glasg.

DONKIN.—On May 30th, Charles Donkin, M.D. Durh., of Bexhill-on-Sea, aged 81.

LAWS.—On May 26th, at Kings Langley, William George Laws, M.B. Edin., F.R.C.S. Eng., formerly of Nottingham, in his 75th year.

## MEDICAL NEWS

### University of Oxford

The following have been elected members of the committee of management of the new institute of experimental psychology: Sir Farquhar Buzzard, Mr. H. H. Price, Dr. R. S. Creed, and Mr. G. D. H. Cole.

### University of Cambridge

On May 30th the following degrees were conferred:

*M.D.*—W. A. Bourne, C. J. M. Dawkins, W. H. Poole, and H. H. Swift.

*M.B., B.Chir.*—H. S. Sharp.

*M.B.*—W. M. L. Owen, C. G. Pantin, J. H. Patterson, and E. G. Pyne.

*B.Chir.*—K. O. Black, J. R. Bodington, A. B. R. Finn, and E. O. C. Grattan.

### Society of Apothecaries of London

The following candidates have satisfied the examiners for the Mastery of Midwifery:—

Monica M. M. M. Fisher, A. L. Gilbey, G. P. Goodwin, Gwynedd Hugh-Jones, Margaret J. T. Leitch, Dorothy Makepeace, M. Y. Paget, and J. H. Spence.

### Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on June 1st, with Prof. Archibald Young, the president, in the chair, the following were admitted to the fellowship: William Beattie, John Fleming, William Ian Gordon, Ronald Guthrie Lendrum, and James Wallace Macfarlane (Glasgow), Joseph Charles Pinch (Canada), David Ross (Maybole), and Archibald McLellan Wright Thomson (Glasgow).

### Queen's University, Belfast

On July 10th the honorary degree of LL.D. will be conferred on Prof. D. J. Coffey, president of University College, Dublin, and the honorary degree of D.Sc. on Dr. T. H. Milroy, emeritus professor of physiology in the University.

### Macalister Lecture

On Thursday, June 25th, at 9 P.M., at the National Temperance Hospital, Hampstead-road, London, N.W., Sir Francis Fremantle, M.P., will deliver the annual Macalister lecture. His subject will be A Doctor in Parliament.

### Sussex Medical and Dental Golfing Society

The spring meeting of this society will be held on Sunday, June 14th, at the West Sussex golf club, Pulborough. The hon. secretary's address is 16, The Drive, Hove, 3.

### Ex-Services Welfare Society

A conference has been arranged by this society to be held at the Hyde Park Hotel, London, on July 3rd with Dr. Edward Mapother in the chair. The subject for discussion will be some of the sequels of war stress. Further information may be had from the secretary of the society, 51, Victoria-street, London, S.W.1.

### Indian Medical Service

The annual dinner will be held at the Trocadero Restaurant, London, on Wednesday, June 17th, at 7.15 P.M., when Major-General Sir Robert McCarrison, C.I.E., will preside. Officers can arrange to sit near their friends, as separate tables to seat eight will be provided. Tickets from the joint hon. secretary, Sir Thomas Carey Evans, Hammersmith Hospital, Ducane-road, London, W.12.

### International Hospital Association

A national council of this association has been set up in this country which includes three representatives of every association interested nationally in any aspect of hospital service. Associate members, of whom there is a growing body in Great Britain, will also be represented on the council. The British Medical Association, the British Hospitals Association, the British Hospitals Contributory Schemes Association, the College of Nursing, the Royal Institute of British Architects, the Incorporated Association of Hospital Officers, the National Association of Local Government Officers, and the Pharmaceutical Society of Great Britain have already expressed their desire to become members.

THE deaths are announced this week of two prominent English medical workers in China. John Howard Wright, the well-known medical missionary, died at Tientsin on May 30th, and Dr. Agnes Livingstone-Learmonth, C.B.E., of the Yenching University, Peiping, on May 10th.

Dr. James McLauchlan Johnston has been appointed a deputy commissioner of the Board of Control for Scotland.

### King's College Hospital

The King has granted his patronage to this hospital.

### St. Mark's Hospital, London

Lord Harewood will lay the foundation-stone of the nurses' home of this hospital on Thursday, June 11th, at 2.30 P.M. A balance of £38,500 is still required to open the home free of debt. It provides accommodation for 50 nurses and 27 maids. During 1935 the hospital admitted more patients than in any previous year of its history, yet the waiting-list is greater than ever.

## Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

### SOCIETIES

**MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.**  
THURSDAY, June 11th.—8.30 P.M. (11, Chandos-street, W.), Symposium on Psychotherapy in General Practice.

**RESEARCH DEFENCE SOCIETY.**  
TUESDAY, June 9th.—3 P.M. (London School of Hygiene, Keppel-street, W.C.), Sir Malcolm Watson: Manson, Ross, and Reed, Pioneers in Research on Tropical Diseases. (Stephen Paget Lecture.)

**ASSOCIATION OF CLINICAL PATHOLOGISTS.**  
SATURDAY, June 13th.—9.45 A.M. (17, Stonegate-street, York), Mr. E. J. King, Ph.D.: Phosphatase as a Test of Hepatic Function. Dr. F. S. Fowweather: Some Observations on the van den Bergh Reaction. Dr. Alan Moncrieff: Jaundice in Children. Dr. A. F. S. Sladden: Two Anomalous Cases of Icteric Tinge. Dr. Howard Collier: "Lead Action" as a Clinical Entity and as a Problem of Clinical Pathology. Dr. King and Mr. G. A. D. Haslewood, Ph.D.: Improvements in the Estimation of Bilirubin. Dr. S. C. Dyke: Adenomatosis of the Liver.

**SOUTH-WEST LONDON MEDICAL SOCIETY.**  
WEDNESDAY, June 10th.—9 P.M. (Bolingbroke Hospital, Wandsworth Common), Sir Lenthal Cheate: The Relationship of Experimental Pathology to Human Carcinoma. (Bolingbroke Lecture.)

**BRITISH ASSOCIATION OF RADIOLOGISTS.**  
FRIDAY, June 12th, and SATURDAY.—Annual General Meeting at Manchester Royal Infirmary.

**PADDINGTON MEDICAL SOCIETY.**  
TUESDAY, June 9th.—9 P.M. (Great Western Royal Hotel, W.), Dr. A. Baldie: Prospect and Retrospect. (Presidential Address.)

**BIOCHEMICAL SOCIETY.**  
FRIDAY, June 12th.—2.30 P.M. (Marischal College, Aberdeen), Short Communications.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF PHYSICIANS, Edinburgh.**  
MONDAY, June 8th, and TUESDAY.—5 P.M., Sir Thomas Lewis, F.R.S.: Symptoms and Signs of Embolism in the Limbs with Special Reference to Pain. (Alexander Gibson Lecture.)

**CHADWICK TRUST LECTURE.**  
THURSDAY, June 11th.—5 P.M. (Chelsea Physic Garden, Swan Walk, S.W.), Sir William Willcox: Plant Pharmacology and Medical Practice.

**BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.**

MONDAY, June 8th.—2.15 P.M., Dr. Duncan White: Radiological Demonstration. 3.30 P.M., Mr. Bright Banister: Fibromyoma of Uterus.

WEDNESDAY.—Noon, clinical and pathological conference (medical). 2.30 P.M., clinical and pathological conference (surgical).

THURSDAY.—2 P.M., Dr. Chassar Moir: Operative Obstetrics. 3 P.M., Dr. R. A. Young: Non-tuberculous Pulmonary Diseases.

FRIDAY.—2.15 P.M., Dr. A. A. Davis: Gynaecological Pathology.

Daily, from 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetrical and gynaecological clinics or operations, and refresher course.

**FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**

MONDAY, June 8th, to SUNDAY, June 14th.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Afternoon M.R.C.P. course in neurology and psycho-

- pathology.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Tues. and Thurs., at 8 P.M., clinical and pathological M.R.C.P. course.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. All-day course in gynaecology.—ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. Thurs., 8.30 P.M., Dr. Roland T. de Hellebranth (New Jersey, U.S.A.): The Present-day Treatment, in the United States, of Gastric and Duodenal Ulcers (open to non-members).—CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C. Sat. and Sun., course in obstetrics.—Courses are open only to members.
- HOSPITAL FOR SICK CHILDREN**, Great Ormond-st., W.C. WEDNESDAY, June 10th.—2 P.M., Mr. Twistington Higgins: Intussusception, Volvulus, and Mesenteric Anomalies. 3 P.M., Dr. A. Signy: Food Poisoning. Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.
- INSTITUTE OF CHILD PSYCHOLOGY**. WEDNESDAY, June 10th.—6.15 P.M. (Friends House, Euston-road, N.W.), Prof. R. J. S. McDowall: Some Aspects of Environment and Character. 8.15 P.M., Dr. Margaret Lowenfeld: Function of Thought in Creation of Character.
- SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION**. WEDNESDAY, June 10th.—4 P.M. (St. James' Hospital, Ouseley-road, S.W.), Dr. C. E. Lakin: Demonstration of Medical Cases.
- UNIVERSITY OF BIRMINGHAM**. TUESDAY, June 9th.—3.30 P.M. (General Hospital), Mr. Stirk Adam: The Treatment of Otitis Media and its Complications. FRIDAY, June 12th.—3.30 P.M. (Queen's Hospital), Mr. Hugh Donovan: Recent Advances in the Treatment of Diseases of the Male Genital System.
- MANCHESTER ROYAL INFIRMARY**. TUESDAY, June 9th.—4.15 P.M., Mr. J. P. Buckley: Some Observations on the Surgery of the Gall-bladder. FRIDAY.—4.15 P.M., Mr. D. M. Sutherland: Demonstration of Surgical Cases.
- ANCOATS HOSPITAL, MANCHESTER**. THURSDAY, June 11th.—4.15 P.M., Dr. W. J. S. Reid: Neurasthenia.
- 
- ## Vacancies
- For further information refer to the advertisement columns*
- Accrington, Victoria Hospital**.—H.S. £150.  
**Albert Dock Hospital, Connaught-road, E.**—Res. M.O. At rate of £110.  
**Ashton-under-Lyme, District Infirmary**.—Res. Surg. O. Also H.S. At rate of £200 and £150 respectively.  
**Barking Borough**.—Asst. M.O.H. and Asst. School M.O. £600.  
**Barnsley, Beckett Hospital and Dispensary**.—H.P. £200.  
**Bedford County Hospital**.—First H.S. At rate of £155.  
**Belfast, Royal Maternity Hospital**.—Res. H.S. At rate of £100.  
**Birmingham and Midland Hospital for Women**.—H.S. At rate of £100.  
**Birmingham City Education Committee**.—Asst. School M.O. £500.  
**Birmingham, Selly Oak Hospital**.—Res. Surgeon. £700. Pathologist. £750. Also Radiologist. £800.  
**Blackburn County Borough**.—Asst. Dentist. £450.  
**Bolton Infirmary**.—H.S. £125.  
**Bradford, Royal Eye and Ear Hospital**.—H.S. £160.  
**Bristol General Hospital**.—Two H.P.'s, three H.S.'s, Res. Obstet. O., H.S. to Spec. Depts. At rate of £80. Also Cas. H.S. At rate of £100.  
**Bristol Royal Infirmary**.—Sen. Res. M.O. £200.  
**Bristol, Southmead Municipal General Hospital**.—Jun. Asst. Res. M.O. At rate of £200.  
**Burnley, Municipal General Hospital**.—Jun. Res. M.O. £150.  
**Burton-on-Trent General Infirmary**.—H.S. £150.  
**Cambridge, Addenbrooke's Hospital**.—Res. Anaesthetist and Emergency Officer. At rate of £130.  
**Cardiff, University College of South Wales and Monmouthshire**.—Lecturer in Experimental Physiology. £750.  
**Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.**—Third Res. H.S. At rate of £75. Also Hon. Assts. in Out-patient Dept.  
**Chester City (Public Assistance) Hospital**.—Jun. Res. M.O. £200  
**City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.**—Surg. and Med. Regs. £225 and £175 respectively. Also Asst. Radiologist.  
**Colchester, Essex County Hospital**.—H.P. £150.  
**Connaught Hospital, Wallhamston, E.**—H.S. and Cas. O. Each at rate of £100. Hon. Physician. Also Sen. Res. M.O. and H.P. At rate of £150 and £100 respectively.  
**Doncaster Royal Infirmary**.—H.P. At rate of £175.  
**Dreadnought Hospital, Greenwich, S.E.**—Receiving Room Officer. Also H.P. At rate of £200 and £110 respectively.  
**Dunedin, N.Z., Olago Hospital**.—Radiotherapist. £800.  
**Edmonton Urban District Council**.—Asst. M.O.H. and Asst. School M.O. £550.  
**Elizabeth Garrett Anderson Hospital, Euston-road, N.W.**—H.P., three H.S.'s, and Obstet. Surgeon. Each at rate of £50.  
**Haliyar Royal Infirmary**.—Third H.S. At rate of £150.  
**Hammersmith Hospital, Ducane-road, W.**—Asst. Radiologist. £700.  
**Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.**—H.S. At rate of £100.  
**Holt, Norfolk, Kelting Sanatorium**.—Second Asst. Res. M.O. £350.  
**Hospital for Sick Children, Great Ormond-street, W.C.**—Cas. M.O. £175. Ophth. Surgeon. Also Res. Aural Reg. £150.  
**Hospital for Tropical Diseases, Gordon-street, W.C.**—H.P. At rate of £120.  
**Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.** Res. H.P. At rate of £100.  
**Huddersfield, St. Luke's Hospital**.—Res. M.O. £200.  
**Hull, Municipal Maternity Home and Infants' Hospital, Hedon-road**.—Sen. Res. M.O. £450.  
**Hull and Sculcoates Dispensary**.—Res. M.O. £500.  
**Ilford, King George Hospital**.—Res. Cas. O. and Surg. Reg., Res. Med. Reg. Each £150. Two Res. H.S.'s. Each £100.  
**Ipswich, East Suffolk and Ipswich Hospital**.—H.S. £144.  
**Kent County Council**.—Asst. for Tuber. Administration. £900. Also Asst. for Hospital Administration. £800.  
**Kettering and District General Hospital**.—Second Res. M.O. At rate of £125.  
**Kidderminster and District General Hospital**.—H.S. £150.  
**Leeds University**.—Lecturer in Biochemistry. Also Lecturer in Physiology. Each £500.  
**Leicester City Mental Hospital, Humberstone**.—Sen. Asst. M.O. £700.  
**Liverpool, David Lewis Northern Hospital**.—H.S. to Spec. Depts. At rate of £80.  
**Liverpool Hahnemann Hospital, Hope-street**.—Res. M.O. At rate of £120.  
**Liverpool Sanatorium, Delamere Forest, Frodsham**.—Second Asst. to Med. Supt. £250.  
**Liverpool, Smithdown-road Hospital**.—Res. Asst. M.O. £200.  
**Liverpool University**.—Supervisor of Dental Mechanics and Dental Prosthetics. £750.  
**London County Council**.—M.O. (Grade I.). £350. Asst. M.O.'s (Grade II.). Each £250. Also Temp. Dist. M.O. At rate of £235.  
**London University**.—Examinerships.  
**Maidstone, West Kent General Hospital**.—H.S. £175.  
**Manchester, Ancoats Hospital**.—Res. Surg. O. £200. Also Combined H.S. (Aural) and H.P. post. At rate of £100.  
**Manchester, Christie Hospital and Holt Radium Institute, Withington**.—Res. Surg. O. At rate of £150.  
**Manchester, Hulme Dispensary**.—Res. M.O. £250.  
**Manchester, St. Mary's Hospital**.—Four H.S.'s for Special Depts. Each at rate of £50.  
**Marie Curie Hospital, 2, Fitzjohn's-avenue, N.W.**—Res. M.O. £100.  
**Monmouthshire County Council**.—Asst. M.O. £500.  
**National Hospital for Diseases of the Nervous System, Queen-square, W.C.**—Registrar. £300.  
**National Temperance Hospital, Hampstead-road, N.W.**—Res. M.O. At rate of £175. Cas. O. and H.S. At rate of £120. and £100 respectively. Also Surg. Reg. 40 guineas.  
**New Zealand, Wellington Hospital Board**.—Asst. Supt., Medical. £1000.  
**Nottingham General Hospital**.—H.S. At rate of £150.  
**Nottingham Hospital for Women**.—H.S. At rate of £150.  
**Paris-Hertford British Hospital**.—Res. M.O. £150.  
**Plymouth, Prince of Wales's Hospital, Greenbank-road**.—Res. Anaesthetist and H.S. At rate of £120.  
**Portsmouth and Southern Counties Eye and Ear Hospital**.—Hon. Asst. Ophth. Surgeon, Hon. Anaesthetist. Also H.S. At rate of £120.  
**Preston and County of Lancaster Royal Infirmary**.—Cas. H.S. £150.

**Wolverhampton Education Committee**.—Asst. M.O. £600.  
**Wolverhampton Royal Hospital**.—H.S. At rate of £100.  
**Worksop, Victoria Hospital**.—Jun. Res. £120.
- The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Lanchester, Co. Durham.

## NOTES, COMMENTS, AND ABSTRACTS

## SOME PSYCHOLOGICAL FACTORS IN SICKNESS ABSENTEEISM \*

BY THOMAS M. LING, B.M. Oxon., M.R.C.P. Lond.

MEDICAL OFFICER, JOSEPH LUCAS LTD., BIRMINGHAM

*(Concluded from p. 1276)*

## Obsessional Manifestations

Although the majority of the psychoneuroses that go to swell the sickness figures of the country are examples of the anxiety state, mention must be made of the obsessional cases, especially as these are more particularly liable to occur among more educated people and those in administrative positions. One of the best descriptions is to be found in "The Nervous Temperament,"<sup>3</sup> where Prof. Culpin outlines the condition as follows:—

"The sufferer says he is forced to think certain thoughts—which may be emotionally unpleasing, apparently futile or abstractly speculative, while recognising them as irrational. The penalty of fighting against them, even when that is possible, is great stress."

James<sup>7</sup> describes the state as a "gnawing craving urgency" and the symptoms are called obsessional: "they rarely display their mental state; they believe strongly in the power and importance of self-control, which they exercise consciously in various directions. They tend to overwork, and give the impression of taking the line of greatest resistance. When a breakdown comes, it is usually ascribed to overwork, though the overwork itself is a symptom and not the cause of the state. They may be over-conscientious either in general or merely with regard to some particular situation."

In my experience it is very rare to find the obsessional state alone among those in employment, and there is nearly always an admixture of anxiety symptoms as well. The following case illustrates a typical example:—

A sorting clerk, aged 22, was frequently ill for a few days at a time with "rheumatism" and dysmenorrhœa. She was the elder of two children and as a child had been under observation intermittently at a leading children's hospital for rheumatism and early cardiac involvement. The home life was fairly happy, although she had a strong antipathy to her father. There had been no rheumatic pains for eight years until she had started work twelve months previously. Further inquiry elicited the fact that the "rheumatism" was always in the sacro-iliac region and only came on when she got "all upset." Actually the pain was identical with the low back pain associated with the dysmenorrhœa. It appeared that she became "upset" as a result of thinking she would go mad and that this feeling came on when there was any rush of work. She kept feeling that she had put two invoices in an envelope instead of one and then wanted to retrieve the envelope to rectify the mistake. As would be expected the same problem presented itself at home: after locking up at night, she always had to go back to make sure that she had really done it. There was marked claustrophobia. "I feel all shut in in a crowd and can't go in a bus; it is the same in a cinema; I can only sit at the end of the row, as otherwise I feel so sick I have to go out." She counts things over and over again, especially houses in a street. Physical examination showed a faint impurity of the apical first sound with no detectable cardiac enlargement and an excellent response to exercise. No other stigmata of rheumatism were found and the general physique was excellent.

In this case the outstanding feature is the marked obsessional symptoms, and when they become incapacitating the patient develops a severe "rheumatic" pain, which

is, of course, an acceptable manifestation to her sub-conscious mind and incidentally one that secured for her a considerable amount of attention during her childhood. The patient was reassured that she was not going mad and was given some understanding regarding the prevalence of obsessional symptoms among the normal population. On learning that she was really just like many people as regards her modes of thinking, the relief was quite dramatic; she still suffers somewhat from dysmenorrhœa, although she has not lost any more time and has had no further "rheumatic" pains during the last four months.

## Extent of Psychoneurotic Illness

Prof. Culpin and Dr. May Smith<sup>3</sup> found significant degrees of neuroticism in approximately 30 per cent. of over 1000 clerical and factory workers, but of not a sufficient degree to incapacitate them from holding their place in the industrial structure. Dr. Halliday,<sup>8</sup> a regional medical officer under the Insurance Act in the Glasgow area, has recently published a most valuable paper which summarises the results of examining 1000 consecutive cases of panel patients who have been absent for more than twelve weeks under the N.H.I. As he points out:—

"The Act had been in operation for twenty years before a survey was made of the reasons for incapacity given by insurance practitioners on the medical certificates. In Scotland, in 1932, the Department of Health issued its first report on the subject. This dealt with the sickness statistics for the insured population for the year from July 1st, 1930, to June 30th, 1931. It was followed by similar surveys for the corresponding annual periods of 1932 and 1933. What information do they contain about the reason for incapacity? Averaging the figures for the three years under survey, the group of "respiratory diseases" occupied first place, being responsible for 42 per cent. of all incapacities. Tying for second place came "rheumatism" and diseases of the digestive system, each providing 10-11 per cent.; violence and skin affections were next, each providing 8-9 per cent. What part is played by the psychoneuroses? A very small part according to the reports—not more than 2 per cent.—and this figure is made up by including such cases as "cardiac debility" and "tachycardia." This picture of the overwhelming predominance of organic disease conflicted with the impression I had found while acting as a medical referee under the Insurance Act. . . . Many of these patients were unfit to work, but the reason for their defective function was, in my opinion, not organic but psychological."

As a result of this inquiry Dr. Halliday has shown that one-third of these patients were disabled primarily by a psychoneurotic condition and that minor associated physical disorders were not in any way the cause of their absenteeism. His figures do not reflect the incidence of psychoneurosis among all the patients examined, but only its occurrence when it acted as the reason for incapacity. A somewhat comparable inquiry was carried out in 1930 among industrial workers in the United States by Dr. C. P. McCord.<sup>9</sup> He investigated a large group of train despatchers, who sit at desks wearing a telephone receiver over one ear and receive as many as 200 items per hour for record or a decision that may involve life and death for train passengers or crews. There is thus present a constant source of fear and McCord found that 82 per cent. of these train operatives showed cardiac disturbances, of a type comparable to the "soldier's heart" or D.A.H. that arose in such large numbers under comparable conditions during the late war.

In view of the importance of the subject, I have analysed the case records of 200 consecutive cases of sick employees, who have been seen either on their return to work after sick leave or who have been referred for an opinion owing to prolonged absence. It should be realised that the policy of the organisation towards their sick employees is a generous one.

\* Paper read before the Association of Industrial Medical Officers at the London School of Hygiene and Tropical Medicine on March 27th, 1936.

The staff receive full pay, while in the case of workers the N.H.I. money is augmented from a special fund, the amount being dependant on the individual's social conditions in each case. In no instance is a worker discharged from the company on account of illness. Naturally the diagnosis varies widely and such indefinite terms as "gastritis," "respiratory catarrh," and "anaemia" are frequently found. The relative unimportance of the actual diagnosis placed on the certificate has been referred to by Culpin,<sup>3</sup> Howe,<sup>4</sup> Ross,<sup>5</sup> Halliday,<sup>6</sup> and Lockhart.<sup>7</sup> The latter has summed up the situation appropriately:—

"These stereotyped descriptions of highly complicated processes are, with few exceptions, valueless to the student of social problems. The certificates deal largely with symptoms or symptom-complexes, to which orthodox labels have been given. They are merely evidence that a person is ill and is entitled to sick benefit."

Most panel practitioners, with whom the matter has been discussed, agree with this, but unfortunately the patient is the unwitting victim of a bureaucratic and medical subterfuge as the presence of a certified "disease" provides him with just the honourable but regressive escape that he is seeking, to protect him from having to deal with the situation in an appropriate manner. Owing to the totally inadequate training in the subject given to the average practitioner, the latter tends to react to the situation in a comparable way, and emphasises the organic symptom as a protective mechanism against his own ignorance of mental processes.

Perhaps one of the most significant facts is the extent to which the "diagnoses" on the sick notes are in reality monosyllabic descriptions of one or other manifestations of the anxiety state; "tachycardia," "gastritis," "rheumatic chill," and "abdominal pain" reappear with monotonous regularity, but in my experience even an organic label, such as "bronchitis" or "tonsillitis," fails not infrequently to manifest any of the physical signs so assiduously learnt and memorised by the student, and masks an underlying emotional disharmony.

#### An Assessment of Incapacity

In the survey referred to above the degree of psychoneurotic symptoms has been ascertained and an assessment made of the extent to which they are incapacitating the patients from following their normal course of employment. The cases have been allotted to one of the following three groups:—

*Group 1: A recognised physical disorder.*—Forty-one per cent. of the cases that have come under observation, either on their return to work or as a result of prolonged absence, fall into this group. The following case illustrates the chief characteristics of those included under this heading:—

A woman, 23 years of age, the eldest of four children, had been away for two weeks as a result of tonsillitis and had been in bed for one week. During her illness she had marked dysphagia and swelling of the cervical glands, and when seen there was still some infection of the anterior pillars. She volunteered the information that she was glad to be back at work; "it's so much nicer with the rest of the crowd, they are all so friendly." During her leisure she goes to cinemas with her boy and goes cycling with the club. Does not get worried; always feels fresh in the morning; rather likes noise. When asked how she felt if sent for by the foreman she replied: "Oh, I don't mind; he's a good scout and I do my best, so why worry?"

This is a case of a well-adjusted happy individual, who is able to feel comfortable both with herself and with her fellow-workers. There are no complaints about noise or supervision, the two outstanding factors upon which so many workers tend to project their own disharmonies.

*Group 2: Definite psychoneurotic symptoms* complicating and prolonging absence due to a recognised "organic" disease; 32 per cent. of the

cases fall into this group, of which the following is a typical example:—

A woman, aged 27, had been away for nine months with heart disease, which was attributed to frequent attacks of influenza. There was an indefinite history of rheumatism as a child with irregular attacks of growing pains. She was the fourth of six children and had been living with an uncle for some years. She was perfectly well until May, 1935, when she was transferred, against her wishes, from one factory to another. At the end of June, 1935, she went to bed with an attack of influenza characterised by general lassitude, headaches, and pains in the arms, and remained in bed until November. She had been engaged for two years and by the summer of 1935 the young man was getting impatient on their getting married, which the woman was very loth to do. As she expressed it: "Of course, if I had not got ill I should be married by now; it was worrying me for months and I could not sleep." In addition she gave a history of marked fear of the dark and claustrophobia, with generalised anxiety if she ever had to go in buses.

When seen she had evidence of well-compensated mitral incompetence with an excellent response to exercise. She stated that she did not yet feel well enough to work, as she "kept on getting so worried over everything." Her domestic situation was discussed briefly and it was obvious that she was lacking courage to break off her engagement and she was consequently given some help and reassurance on the subject. A week later she returned to say that she now felt perfectly well and quite fit to return to work; she had solved her problem by breaking off her engagement and since then has kept perfectly well.

This is a case showing an admixture of organic disease in the shape of a rheumatic carditis undoubtedly prolonged by an associated emotional condition.

*Group 3.*—Cases where the manifestations are essentially emotional in origin and the individuals either state that they are away on account of "nerves" or complain of disharmony in various systems of the body without clinical evidence of pathological change; 27 per cent. of the cases away for more than two weeks are under this heading, and the following case illustrates the chief points at issue:—

A man, aged 20, was seen as he had been away for three weeks with "palpitation." He gave a history of generalised fear and worry for the last three months. Further inquiry elicited the fact that he was the only son of a man who had shell-shock during the war and had been unable to work ever since. The home atmosphere had always been one of apprehension and the boy was deeply attached to both parents. Two years previously he had married against his parents' wishes and his married life had been fraught with many difficulties. He kept wanting to return home and a month before he went "ill" he was separated from his wife and he returned to his parents' home.

The physical examination was essentially negative and his inner disharmony was manifested by numerous complaints about his heart, although his cardiovascular system was clinically normal.

As would be expected in this case, the individual was dissatisfied with his work and decided to seek employment elsewhere. Admittedly the demarcation between the various groups is somewhat arbitrary, as the diagnosis of a psychoneurosis is arrived at, as in other causes of incapacity, by a combination of many points of medical evidence, no one of which is typically diagnostic of anything in particular, but which, in combination, lead to a judgment of causes as sound as in organic disease.

#### The Remedy

Here then is a major problem, social, economic, and medical, that is yearly becoming more pressing and is of equal interest to those who are responsible for training doctors and to those, like ourselves, whose duty is primarily towards the patient, his environment, and his occupation. It is generally agreed that the seeds of adult neuroticism are sown in the

first few years of life and in this connexion the problem is comparable to the prevention of crippling among children and young adults. Correct feeding and the prevention of rickets is all-important and is indicated for all children; in the same way good mental health for all children is just as attainable, and I believe that the next 30 years will witness as great a development along these lines as the present century has evidenced in the prevention of crippling. When adolescence is reached the problems of the rapid changes of advancing maturity demand our help and guidance; day continuation schools, as empowered by the Hadow Act, should be a much bigger feature of industry than they have yet become, and the teaching of a sound biological approach to life and its situations should be an integral part of the curriculum.

On the medical side a complete reorientation of viewpoint is required, and this must be started in the formative years of the medical student's life. He must be taught to view the patient as a living integrated whole and in relation to his home circumstances and his occupation. As Sir Walter Langdon-Brown<sup>10</sup> points out it must be realised "that the boundaries of medicine are contemporaneous with life. Medicine touches life at every point." It is generally asserted that the development of scientific methods of investigation, radiological, pathological, and biochemical, which have of necessity to be centralised in hospitals and clinics, has robbed the general practice of medicine of much of its interest and that many family doctors are just "sign-posts" to the specialists and technical experts. Such an attitude seems most regrettable, but actually the situation is a real opportunity for the regeneration of the practice of medicine along broader and more productive lines. The practitioner has a unique opportunity to investigate and assess the various environmental and social factors mentioned previously, and this privilege is especially opportune among those intimately concerned with the industrial setting. We have an opportunity of observing the effect of seed on soil, and even more important, of improving the soil and at the same time of moving the growing seed to the most suitable soil for its own constitution.

Our approach to the patient must be essentially biological and all aspects of the case, physical, emotional, and environmental, must be brought forward and the relative importance of each factor assessed in determining the aetiology of the condition and the appropriate treatment. Though not infrequently one meets with cases for whom one can do comparatively little, either because the mental calibre is inherently too poor to mould towards a better condition, or because they are the victims of an environment from which they neither can escape nor to which they can adjust, nevertheless it is certain that the majority of people can be helped very appreciably. To not a few, the mere fact that the sufferer finds a sympathetic and understanding listener who does not laugh at him or tell him that there is nothing the matter with him, is a source of very real comfort and is sufficient help to enable him to face his problems on a more realistic basis, and to take a more roseate view of the future. Where facilities occur for some suitable adjustment to be made in the type or conditions of employment, there is an added therapeutic weapon of very real value and one that we in this room are especially in a position to utilise to the full. Quite apart from a change of occupation, it frequently happens that the neurosis has been precipitated by a conflict of personalities and in such cases it is often possible to give the person in authority some understanding of the situation and suggestions for remedying it.

There is no value in a vague eclecticism or a dilettante recognition of the psychological factor in disease, but once it is realised that every patient is an individual suffering from "dis-ease," due to a number of contributory factors, both physical and mental, and worthy of our help, irrespective of the extent and objectivity of the underlying patho-

logy, a new viewpoint in medicine is opened up. This aspect, frequently referred to as the Neo-Hippocratic approach, is in reality a return to Hellenic medicine from the materialism of the last century, and Plato in the *Dialogues*<sup>11</sup> epitomises the situation for us in the words that he attributes to Socrates: "And, therefore, if the head and body are to be well you must begin by curing the soul," that is the first thing . . . and he who taught me the cure and the charm added a special direction "Let no one," he said, "persuade you to cure the head until he has given his soul to be cured, for this is the greatest error, that physicians separate the soul from the body."

## A JEWISH MEDICAL CENTRE

At a time when the problems of Palestine have been forced on the attention of the British public it is interesting to hear of a large scheme of medical development now being undertaken by the Jewish authorities. As we reported last March, Dr. J. J. Golub, of New York, was asked to act as consultant in planning a new medical centre to be built on Mount Scopus, Jerusalem, beside the Hebrew University. He informs us that the Hadassah and the American Jewish Physicians' Committee in New York have obtained land, are raising the funds, and have drawn plans for this new medical centre that will equal, in standards of medical care and possibilities in medical education and research, the best of such institutions in America and Europe. It will consist of six buildings, namely: (a) a main hospital building (about 260 beds); (b) a maternity building; (c) a professional and administrative building for the X ray and radium institute, operating rooms, and the general administration; (d) an out-patient department; (e) the Henrietta Szold school of nursing; and (f) the Nathan Ratnoff medical school. The group will be known as the Rothschild-Hadassah University Hospital and the Medical School.

"Wherever Jews live in large numbers," Dr. Golub says, "one often hears questions as to whether Jewish health agencies supported by Jews and serving Jews are needed; as to whether a medical school under Jewish auspices should be established. In so far as these questions concern Palestine, they have been answered clearly and definitely, since the plans, the building programme, and affiliation arrangements between Hadassah and the Hebrew University have been agreed upon and approved by all persons concerned, and have been endorsed and supported by thinking leaders of Jewish life in Palestine and elsewhere." The new medical centre will further medical education by providing hospital clinical appointments, and university recognition of the best qualified in the profession. It will create opportunities for scores of German Jewish refugee physicians who seek a new home in Palestine, and it will have about 20 places for interns. Palestinian girls will be trained as nurses with a curriculum covering three years. The medical school building, it is stated, will contain facilities for research on cancer, hormones, parasitology, bacteriology, physiological chemistry and pathology. Patients' wards will be no larger than of six beds each for adults, and eight beds for children, with adjoining smaller wards of two and three beds. Single rooms are provided for acutely sick patients, for isolation of patients with contagious diseases, and also for private patients.

The work of construction will begin on July 1st, and it is hoped that the centre will be a model institution for the East. The architect is Mr. Erich Mendelsohn.

### COMFREY

COMFREY is a forgotten "wort" and Dr. Macalister in an engaging little book<sup>1</sup> gives the results of his investigations into this ancient remedy. It was known to the Turks and Saracens as "wound wort," and for centuries was held in high repute by the medical profession.

Dr. Macalister's interest in comfrey was aroused by reading a paper in THE LANCET of 1896 by Prof. W. Thompson, and he then began a careful investigation and was stimulated to carry out numerous experiments in the clinical material at his disposal. He gives the results of these experiments which prove that the mucilaginous infusion of the powdered root has a distinct and undeniably beneficial effect on the healing of serious and intractable ulcers.

Dr. Titherly was able to isolate a crystalline solid, allantoin, from the root of comfrey and this substance was found on experiment to have a certain definite therapeutic action. It is primarily a cell proliferant and it has in addition the power to produce rapidly a frank leucocytosis. When applied in solution to ulcers or when injected into the bulb or stem or plants the results are obvious to the naked eye. Its value in the treatment of pneumonia and peptic ulcer is less easy of demonstration, but the reader will find some interesting speculations in regard to this aspect of its therapeutic action.

From ancient times comfrey has been known and used as a curative agent, and even to-day the country people have faith in comfrey as a healer. Dr. Macalister has shown in this interesting communication the reason for this faith.

### LETTERMANN'S FOOT SUPPORTS

ACCORDING to a report by Dr. W. Bennewitz from the surgical hospital at Wuppertal-Unterbarren, where the foot supports introduced by Dr. A. Lettermann of Berlin have been in use for eighteen months, they are of positive value in many deformities of the foot. Moreover, they have been used with success as a prophylaxis after fractures of the leg have been taken out of plaster-of-Paris. The support is made of a substance which becomes soft when heated, and when plastic is placed in the shoe. When the patient walks about the substance gets squeezed into the hollows of the foot and within ten to twenty minutes hardens to make an accurately fitting support. The support to the arch of the foot is of course not quite as rigid as that of a metal support, but can replace it for most purposes. Apart from actual deformity these supports are claimed to have application in some forms of functional insufficiency. They are distributed in this country by Messrs. Allen and Hanburys Ltd., who supply a booklet setting out the principles of application with extracts from medical reports.

### NEW PREPARATIONS

**CROOKES' SUPER-D OIL.**—The Crookes Laboratories (British Colloids Ltd., Park Royal, N.W.10) offer under this name a standardised natural liver oil of very high potency derived from fishes of the scombridæ family. The vitamin-A content is stated to be 48,000 international units per gramme, and the vitamin-D content 50,000 I.U.—"as much as 500 times the amount of vitamin D as is contained in an average cod-liver oil." The manufacturers refer to recent observations showing that natural vitamin D is not the same substance as calciferol (irradiated ergosterol), being free from toxic substances and effective in smaller quantities. The dosage of Crookes' Super-D oil suggested for rickets is 5000-6000 I.U.

<sup>1</sup> Narrative of an Investigation Concerning an Ancient Medicinal Remedy and its Modern Utilities. By Charles J. Macalister, M.D. Edin., F.R.C.P. Lond., Honorary Consulting Physician, Royal Southern Hospital, Liverpool. London: John Bale Sons and Danielsson Ltd. 1936. Pp. 60. 2s. 6d.

of vitamin D daily, and the convenience of the preparation lies in its high concentration. It is sold in 5 c.cm. vials, with dropper, and each drop is estimated at 1350 I.U. of vitamin D and 1700 of vitamin A. It is also to be had in capsules of 8000 and 10,000 units respectively. Mention is made of the use of vitamin D in massive doses for hay-fever, asthma, and arthritis.

**ACRIFLAVINE B.D. (Intravenous).**—In THE LANCET of Feb. 8th last E. W. Assinder reported good results from the use of intravenous acriflavine as a urinary antiseptic in nearly 5000 cases of acute gonorrhœa. The supplies of acriflavine available in 1932-34 were unsatisfactory because they often caused damage to the liver, shown by jaundice; but in June of last year Imperial Chemical Industries Ltd. produced "an acriflavine which is apparently non-toxic." This is now issued by the British Drug Houses Ltd. (London, N.1) as Acriflavine B.D. (Intravenous). Apart from gonorrhœa Assinder found acriflavine valuable in *B. coli* infections of the urinary tract.

**TRANCUSALVE** is an ointment that has been produced by Transcutan Ltd., Leeds, for painful conditions such as fibrositis, gout, and arthritis. It is stated to contain salicylates, ethereal oils, kieselguhr, and concentrates of certain spa waters, in a lanolin base. The ointment can be thickly smeared over the affected part and may therefore be applied when there is much tenderness. It is supplied in collapsible tubes.

**A GLARE SHIELD FOR SPECTACLES.**—Theodore Hamblin Ltd. (15, Wigmore-street, London, W.1) have improved the Klippon Glare Shield introduced last summer. It consists of two moulded discs of non-inflammable material; an elastic band unites the discs, and its tension is enough for them to grip the frame of any pair of spectacles, to which the device can be fitted in a few seconds. The appearance is then similar to that of ordinary sun-glasses. The shield is cheap, very light, and can be folded into a small purse when not in use. It is produced in three tints: No. 1 is bluish and corresponds to the standard London Smoke No. 3; No. 2 is greenish-yellow and has the same effect on the ultra-violet spectrum as Ficuzal 4; and No. 3 is grey, similar to Crookes' B.2.

Under the title "Medical Products of Precision," Messrs. EVANS SONS LESCHER AND WEBB LTD. (56, Hanover-street, Liverpool) issue a handbook describing the more important of the preparations manufactured at Evans' Biological Institute, Runcom. Among these are standardised sera, vaccines, organo-therapeutic products, and colloidal and other solutions. A supplementary announcement is made about the latest of the Hepatex series of liver extracts, Neo-hepatex, which is recommended for intravenous or intramuscular injection in pernicious anæmia.

**FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.**—Week-end courses will be held in fevers at the Park Hospital (June 20th and 21st); surgery at the Prince of Wales's General Hospital (June 27th and 28th); children's diseases at the Princess Elizabeth of York Hospital (July 4th and 5th); heart and lungs at the Victoria Park Hospital (July 11th and 12th). An all-day course in proctology will be given at St. Mark's Hospital (July 6th to 11th); an afternoon course in dermatology at the Blackfriars Skin Hospital (July 13th to 25th); and a fortnight's course in urology at the All Saint's Hospital (July 13th to August 1st). On Thursday, June 11th, at 8.30 p.m. at the Royal Society of Medicine, Dr. Roland de Hellebranth, of New Jersey, U.S.A., will lecture on the present-day treatment, in the United States, of gastric and duodenal ulcers. All members of the medical profession are invited to be present. Further information about the courses may be had from the secretary of the fellowship, 1, Wimpole-street, London, W.

## ADDRESSES AND ORIGINAL ARTICLES

## ENLARGEMENT OF THE HEART\*

BY JOHN PARKINSON, M.D., F.R.C.P. Lond.

PHYSICIAN TO THE CARDIAC DEPARTMENT OF THE LONDON HOSPITAL; PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART

ENLARGEMENT of the heart touches so many problems in cardiology that it will be impossible to do more than refer to a number of them in two lectures, and it will be necessary to exercise a preference for problems which have come under my own notice. My plan is to take first the methods of examination; then the normal heart and its displacements and fixations; and lastly to speak of dilatation and hypertrophy in general. In the second lecture my main thesis will be that enlargement of the several components of the heart can now be identified by radiology and that it is no longer sufficient to speak of general enlargement alone. There are cardiac affections, notably angina pectoris, where the heart is commonly of normal size and shape; but usually, and often from its beginning, a cardiac lesion is associated with enlargement. For concise information on the history of cardiac enlargement and its physical signs, I would naturally refer you to the Harveian Oration of 1928, by our true knight of learning Sir Humphry Rolleston.<sup>91</sup>

## Methods of Studying Cardiac Enlargement

## THE PERCUSSION METHOD

For 175 years the clinical method of percussion has been in use; in general changing little, though variations in its application have been many. Throughout the relative values of light and heavy percussion in mapping superficial and deep areas of cardiac dullness have been disputed, and not yet has agreement been reached. Such a subjective method must yield a diversity of individual convictions on the correct method of its performance. It is no surprise to find that the area of normal cardiac dullness varies considerably with the authority on clinical methods. Indeed, as a rebuke to dogmatism, these were once collected by Moritz and superimposed to display the varieties of cardiac outlines favoured by famous authorities.<sup>95</sup>

The difficulties inherent in percussion have been glossed over in an amazing way. The stout and the emphysematous are admittedly exempt. A method which disfranchises a majority of women because of their mammary development belongs to the last century and presses for its relegation to that pre-X ray period. The nipple line in men is fairly constant and an indispensable guide, but the mid-clavicular line is difficult to apply and especially in women; it is exact enough at the clavicle, but nothing less than a plumb-line will give it exactness near the apex-beat where we need to use it. Surely it is better to measure outwards from the midline to the apex, and in men to use the nipple line in confirming the position of the apex-beat, an accessory to percussion by no means negligible.

The personal factor in such a subjective method as percussion is enormous and most authorities have felt it incumbent upon them to warn us of the fact. Students, from my time to this, find it almost impossible to avoid percussing preconceived or

dictated ideas into the cardiac outline. They have now ceased to retain the requisite faith in cardiac percussion, and begin to resent the continued insistence on its values in certain quarters. Surely the time has come to revise our opinion of this primitive expedient which has outgrown its usefulness, and to require in the candidate some working knowledge of the radiological method as applied to disease of the heart and great vessels.

The inaccuracy of percussion is inseparable from a method which is indirect and inferential; and this is now generally admitted. No longer shall we tell of the professor who by knocking at the front door could find out who was in the drawing-room. Taking only the right limit of cardiac dullness, Samuel Gee says "in truth . . . not very trustworthy."<sup>42</sup> The transverse diameter on percussion over the convex surface of the chest is in excess of the real transverse diameter on orthodiagraphic projection, and the discrepancy grows when a heart is much enlarged.

The limitations of percussion in cardiac mensuration are best exposed by furnishing examples of the potentialities of X rays. This I hope to show. The need for supporting evidence on enlargement is testified by the increased reliance placed in recent years upon the position of the apex-beat. This is all to the good of diagnosis, and a healthy sign of discontent with percussion methods; but although the apex-beat gives good information about the left border of the heart,<sup>108</sup> it is misleading where there is displacement from any cause. Besides, the apex-beat is not always palpable, and it may seem to be farther out than it really is when there is tachycardia. Moreover, it is now rightly claimed that enlargement of the left ventricle may be assumed if there is clinical evidence of continued hypertension or of aortic incompetence, and that similarly the right auricle will be enlarged if there is distension of the veins of the neck with other signs of congestive heart failure. Thus there is ample scope for thorough clinical observation as a contributory means of inferring or even postulating enlargement.

As a final effort to resuscitate a dying method which is packed with fallacies and imperfections, there have been attempts to square the results of percussion with those of radiology, but they have led to nothing. Percussion had to serve in the past, and it may still serve as a crude expedient in certain cases, but the best proof that it is to be extruded from our important and growing number of clinical and laboratory methods is the fact that it is sterile. The tokens of sterility are upon it. Nothing has been added to medical knowledge or progress through cardiac percussion since the beginning of this century, and in the light of X rays it will shrink into obsolescence.

## THE RADIOLOGICAL METHOD

It was at the close of the last century that X rays were discovered, and their application to the heart was not long delayed. This can well be judged from the remarkable amount of information on the subject of radiology of the thoracic organs to be found in Holzknicht's book<sup>49</sup> published so long ago as 1901. Radioscopy (or fluoroscopy) was used, as well as radiography, though there was a time when they fell largely into disuse owing to fear of X ray effects on the operator. Happily these are now avoidable and avoided. No organ is so well placed for X ray inspection as the heart. It is surrounded by translucent lung, and by rotation of the patient it can be viewed from every angle. Instead of the outline of a cardiac

AA

\* The first Lumleian lecture for 1936 delivered before the Royal College of Physicians of London on March 17th. The second lecture will appear in THE LANCET next week.

superficies obtained mediately by percussion, we see immediately the volume of the heart and the totality of its vascular extensions; and meantime we are watching the contractions of its constituent parts. Here is no single avenue of approach but approach from open country on all sides. We obtain the composite picture of a sum of cardiac aspects, a system of perspectives. X rays tell us literally everything that percussion can tell us and tell it more amply and precisely. "More faithful witnesses are eyes than ears." Its scope goes far beyond the dreams of the past masters or artists of percussion. The superiority and clinical worth of radiology is indisputable; it is as useful as the electrocardiograph and a necessary complement to it. We should be quite indifferent whether it is to be classed as clinical or laboratory, classical or modern, if only it implements our inquiries and facilitates a comprehensive and accurate diagnosis. It cannot or ought not now to be said that it is not readily available; it is available for a trivial surgical or dental defect, so why not to reveal a heart in its fullness?

The chief objection appears to be the fear of restricting the medical student's training in physical methods of a literally handy sort. Training in observation is without doubt an integral and all-important thing; but the more would this be advantaged were it concentrated on inspection, palpation, and auscultation, and were percussion derogated in favour of a more effective X ray inspection. It is as if we lamented the employment of the sphygmomanometer because less stress need now be laid on judgment of tension by feeling the pulse. It has always been permitted to teach students our disbeliefs as well as our beliefs.

#### The Normal Heart Size: Cardiometry

By an enlarged heart, in the clinical sense, is meant a heart which has exceeded the physiological limits of size. It follows that in deciding the question of enlargement, it is of some importance to know what the physiological limits of size are. We may express the absolute size of the heart in terms of weight or volume, but neither can be measured directly during life. Anatomical data are available<sup>102 7</sup> which show that the weight of the heart in health varies within wide limits, but keeps parallel with body-weight. Thus, if the mean heart-weight in men is taken as 300 g., the average heart-weight varies between 215 and 392 g. for body-weights of 50 to 90 kg.—i.e., it almost doubles its weight (Smith). There is no direct relation between heart-weight and stature, nor, according to Smith, between heart-weight and age, as used to be thought. What we require for clinical purposes is not the absolute heart size, but the heart size in relation to bodily size. In radiology, the main difficulty lies in the impossibility of measuring directly the volume of the heart. A measurement made in a single plane such as the width of the heart—i.e., transverse diameter—is no true index of heart volume because the transverse diameter (T.D.) is so much influenced by the position and inclination of the heart in the chest. Thus a short thickset man will have a wider T.D. than a tall slender man of similar body-weight and presumably of similar heart-weight.

The average transverse diameter in healthy adults (orthodiagram in erect posture) varies from 10 to 12.5 cm. according to body-weight, but in any given weight group the maximum and minimum values may differ by several centimetres. The transverse diameter has a limited use to express the full width of the heart shadow in a given patient, and for

comparative measurement in the same patient. Similarly the cardiothoracic ratio—the ratio between the transverse diameter of the heart and the internal diameter of the chest at its base—does often approximate to a figure of 50 per cent. in health, but it is unsafe as a guide to whether a heart is slightly enlarged or not.

The investigations of Bedford and Treadgold<sup>9</sup> in this country and of Eyster and others in America have shown that the cardiac transverse diameter can be more closely correlated with bodily size if height as well as weight is taken into account. The tables constructed by Hodges and Eyster<sup>47</sup> for predicting transverse diameter (or area) from weight and height probably represent the most scientific method of deciding the physiological mean heart size for any given person. Attempts have even been made to estimate the cardiac volume from measurements made in two planes, and Rohrer's method<sup>90</sup> as confirmed and amplified by Kahlstorf<sup>53</sup> appears to give reasonably accurate results.

Cardiometry is so complicated, and so full of pitfalls, that it is scarcely adapted to routine clinical use, though it will always be needed for comparative measurements in the same person and for research purposes. Meanwhile one can form a sound opinion of heart size from simple screen examination without measurements, for radioscopy has the advantage of permitting inspection of the heart from every angle, and estimation by the eye of its size in various planes.

#### The Position of the Heart and its Displacement

The position of the normal heart in the chest varies within wide limits. In general it is expected that about one-third of the projected cardiac area lies to the right of the midline of the body, and two-thirds to the left of it. The heart is moored at its base by the great vessels entering and leaving it—i.e., by the venous mesocardium and the arterial mesocardium (Keith). This fact is well appreciated when the pericardium is opened and the hand grips and moves the heart about on the universal joint formed by the vascular attachments, especially the pulmonary veins, which have to be severed before greater movement is possible. Section of the aorta, venæ cavæ, and pulmonary artery then allows complete excision of the heart. This fixation especially to the pulmonary vessels reminds us of Keith's dictum that "the lungs in all their movements carry their pump with them"<sup>55</sup> Further, that other respiratory organ, the diaphragm, is seen to be of prime importance in deciding the lie of the heart. The axis of the heart may be found at almost any angle between horizontal and vertical. The right ventricle rests lightly on the diaphragm, and the distended lungs keep the heart in place. Any change in position of the heart with respiration has a profound effect on the projected outline of the heart as seen by radioscopy. The heart is no simple geometrical figure, but an irregular cone with its apex passing forwards and downwards to the left. It is this complicated solid, of which we see by radioscopy a silhouette—a section at its greatest diameter in the coronal plane. No wonder there are such variations in the size and shape of the projected outline; indeed, their extent has provoked a certain pessimism in those ambitious for precision in the measurement of an organ so visually accessible as the heart.

The diaphragm appears to be the greatest factor in deciding the position of the heart in health (Fig. 1). The short stout individual with a short wide chest and high diaphragm has a heart tilted upwards and

to the left; the tall thin individual with a long narrow chest and a low diaphragm has a heart swung in towards the middle line. The heart of the one looks large and horizontal; of the other small and vertical. Rotation of the heart on its own axis may also be operative, certainly it can be in mitral stenosis. Consideration of the big difference between the position, shape, and apparent size of the heart in deep inspiration and in expiration will leave no doubt that a substantial variation in shape and apparent size is to be expected in health.<sup>28</sup> There are also distinct differences between records obtained with the subject in the horizontal and in the vertical position, again dependent partly upon the diaphragm; but observations are now usually made with the patient

the heart because the apex-beat is noticeable and about the nipple line or even a trifle beyond. Almost every doctor is aware how important it is to settle the question, for a cardiac defect in youth has greater significance than in the old. The suspicion this apex-beat arouses has been mentioned by Sir Thomas Lewis.<sup>70</sup> It is generally the only doubtful sign, and if there have been symptoms they have been trifling or incidental. The pulmonary second sound may be accentuated, probably from displacement, but murmurs are absent.

For some years I was worried about such an obtusive apex-beat until I happened to notice that these children had often a slight scoliosis of the common type, that is with dorsal convexity to the

FIG. 1.—Displacement of heart upwards and to the left. Pregnancy, ninth month (continuous line); two months later (dotted line).

FIG. 2.—Displacement of heart to right by high position (eventration) of the diaphragm.

FIG. 3.—Displacement of heart to the left by right dorsal scoliosis (shaded portion). Corrected by rotation 10° to the right (dotted line).

standing or sitting, and rightly so for the comfort of a cardiac patient.

In children the diaphragm is relatively high, and the heart looks proportionately large and rounded in a relatively small chest. The manubrio-xiphoid junction is a useful guide to the natural level of the top of the diaphragm in the neutral phase.<sup>6</sup>

The diaphragm is placed high whenever there is undue distension of the abdomen as in obesity or ascites. Then with gas inflating the stomach or colon, it is especially the left dome of the diaphragm which rises like a recording gauge as it carries with it the heart. The usual displacement is upwards and outwards so that the heart seems larger. A less usual displacement, towards the right side, may be produced by a large diaphragmatic hernia. Different in pathology, and less rare, is the eventration or high position (or elevation) of the left dome of the diaphragm which is encountered now and then on routine radiology of the heart. The dome is not broken, and it moves with respiration (and not always badly), but the differentiation from unilateral paralysis or even from true hernia of the diaphragm may require all the technical skill of a radiologist. I have seen this condition with cardiac displacement to the right (Fig. 2), with and without symptoms. As in the common condition of a normal diaphragm with much gas in stomach or colon below it, I find the patient, strangely enough, often denying any knowledge of what flatulence or palpitation may be.

#### Slight Scoliosis a Common Source of Apparent Enlargement

It is a common experience to find that a school child is suspected of having slight enlargement of

right. It was first noticed on radiology, for the heart lies a trifle too far to the left so that perhaps four-fifths of the cardiac shadow instead of two-thirds lies on the left of the midline. Confirmation was obtained by rotating the subject a few degrees to the right when the heart appeared much as one would expect in health, placed normally as regards the middle of the chest, and not at all enlarged (Figs. 3 and 4). In other words, this positional correction removed an illusion of disease. Other features of the uncorrected position are slight accentuation of the aortic knuckle, of the pulmonary arc, as well as of the left ventricle, the three constituents of the left border. When this cause for a displaced apex-beat is suspected, and it should be when the cardiac history is negative and it is the only sign, recourse to radiology will show the appearances here described and examination of the back a slight scoliosis. Owing to rotation of the vertebræ the line of the bodies is more deformed than the line of the spinous processes, so that X rays show the condition to be worse than one would expect from inspection of the back.

Now the radiological changes in the heart from considerable scoliosis have often been described, but it seems to me more important to draw attention to these minor grades which, I am convinced, often explain an erroneous diagnosis of slight enlargement in children of school age. Once recognised as a unimportant and trivial displacement, no further attention need be drawn to the heart in these young subjects; and the school medical officer, nowadays so rightly unwilling to stop games without good reason, can accept this assurance.

In the past it has often happened that this deceptive apex-beat has been attributed to real enlargement

indicating a cardiac lesion, and the stigma has followed a healthy subject perhaps for a lifetime.

Fifty years ago, a young Irish doctor joined the Navy just escaping rejection as the apex-beat was a little out of place. Subsequently doctors used to assign him an hypertrophied or a dilated heart. To-day this man is aged 73 and plays golf without symptoms. The apex-beat is still noticeable, but X rays show a spinal curve to the right and a slight displacement of the heart to the left without enlargement. A glance at the patient's back shows moderate scoliosis with dorsal convexity to the right.

Positional changes of the heart in high grades of scoliosis are known, but not, perhaps, sufficiently

for the acute infarct-pericarditis in healing may initiate a chronic adhesive pericarditis; and 6.2 per cent. of Smith and Willius's<sup>104</sup> cases of adherent pericarditis were ascribed to this.<sup>79</sup>

There appears to be no cardiac enlargement from uncomplicated adhesive pericarditis and when found it is referable to the associated cardiac disease. Calcification of some degree is found post mortem in a certain proportion (about 10 per cent.) of cases of adhesive pericarditis and is considered later.

(2) *Constrictive pericarditis*.—Chronic adhesive pericarditis may cause a constriction of the heart, especially affecting the auricles and, most important

FIG. 4.—Common displacement of heart from slight scoliosis often leading to suspicion of cardiac enlargement.

FIG. 5.—Considerable displacement of heart from scoliosis; apex in left axilla. Superficial resemblance of dorsal curvature to an aneurysm.

FIG. 6.—Displacement of heart to the right—a partial dextrocardia—from scoliosis of the rarer type—i.e., left dorsal convexity.

well known.<sup>98</sup> It was very difficult to credit with a sound heart a woman of 56 showing the X ray picture reproduced in Fig. 5, but her freedom from symptoms and any other sign and a complete investigation in hospital proved that actually she had.

Scoliotic displacement of the heart to the *right* has not the same clinical interest because it is produced by the rarer type of scoliosis, that with dorsal convexity to the left, and because it will scarcely be discovered except by radiology. None the less it is a real source of displacement; and in a recent case it was so pronounced that I took it for an acquired dextrocardia which, in a sense, it was (Fig. 6).

A similar instance, though less pronounced, was a man of 26 who, in 1916, was examined at the Heart Hospital and was rejected for the war because X rays showed the heart displaced to the right as I have been able to confirm from the original notes. This year, twenty years later, I examined him for an illness unrelated to cardiac enlargement, and found that he still showed that cardiac displacement which had for its cause a scoliosis with dorsal convexity to the left.

#### Adherent Pericardium

Four forms of adherent pericardium may be considered.

(1) *Adhesive pericarditis* (non-constrictive).—Obliteration of the sac, partial or complete, is often symptomless and no more than a chance post-mortem finding. In fewer than half the cases so discovered is there any associated cardiac disease.<sup>104</sup> Among these must nowadays be included coronary thrombosis,

of all, the superior and inferior venæ cavæ. Constrictive can only be fairly applied to the chronic process, for although there must be a compressive factor in gross pericardial effusion, the other factors—infected and myocardial—sufficiently obtrude to mask it. The result of chronic constriction is no ordinary heart disease, enlargement, or failure, though from such it has to be distinguished, but a special group of symptoms and signs which were clearly presented to us in London last year by Dr. Paul White in his St. Cyres lecture on chronic constrictive pericarditis (Pick's disease) treated by pericardial resection<sup>116</sup> which was so much appreciated in this country. He said that heart disease itself is a rare association, and that rheumatism has so little a place in its aetiology that the presence of mitral stenosis excludes it. It is a state of *congestion without cardiac failure*. A mechanical obstructive problem, one affecting the inflow of blood to the heart, requires surgical treatment (true cardiolysis, not mere thoracotomy); and further successes as those he already describes would go far to confirm the pathology. No doubt there are mixed cases, where the myocardium is also affected; for example, auricular fibrillation was present in 4 of his 15 cases, and 6 of 17 cases collected by Schur<sup>95</sup> from a different standpoint. The need for strict choice of patients likely to benefit from surgery is apparent, though White says that "the commonly expressed fear that constricting adhesions once removed may reform has proved entirely groundless."

Of his 15 cases, the heart shadow on X ray examination was normal in size in 7, slightly enlarged in 5,

and moderately enlarged in 3 only. As stated, none had mitral stenosis, and of three patients with enlargement of the left auricle (X ray) two had auricular fibrillation. It is because too much attention has been directed to alleged pathognomonic but uncertain signs and too little to the total clinical picture, that the condition has so seldom been recognised.<sup>112</sup>

(3) *Calcified pericardium*.—Although formerly looked upon as a distinct rarity, calcification of the pericardium is more frequent and diagnostically more important than was thought. It was found in 10.4 per cent. of Smith and Willius's series<sup>104</sup> of adherent pericardium, and in 10 per cent. of William Evans's series which is to be mentioned later. It is important because it can now so readily be seen in life with X rays, and because its presence affords a proof of adhesive pericarditis as certain as one could wish. It can be missed on radioscapy or on routine films, but with appropriate technique it can be made obvious either in the anterior or oblique positions.

Yet calcification per se, this conclusive evidence of considerable and long-standing adhesive pericarditis, is commonly found to produce no symptoms of cardiac inadequacy and no enlargement, or no more than could be explained by the superimposition of a much thickened pericardium. I was first impressed by these facts in meeting Vilvandré's patient<sup>111</sup> who was a good walker and free from any but her gastric symptoms.

On the other hand, constrictive pericarditis which is producing symptoms is also often accompanied by calcification as would be expected. It was present, for instance, in 6 of White's 15 cases.

In 1920 I admitted to the cardiac department of the London Hospital a man of 25 who complained of epigastric fullness and was found to have slight enlargement of the liver and a palpable spleen. At that time no cause was found for these signs and he went to live in Canada and did not return until 1930, ten years later, when I saw him suffering from dyspnoea and oedema with enlargement of the liver and spleen as before, but more pronounced. Fortunately on screening I saw the dense shadows of a calcified pericardium (Fig. 7). From 1930 to 1932 he had persistent ascites and oedema though salyrgan often gave him relief. He died in 1932 and Dr. Evan Bedford procured a necropsy. The heart was scarcely enlarged and a thick shell of calcification enclosed it. This was probably a case which earlier in its course might have been considered suitable for cardiolysis on the lines discussed by White.<sup>116</sup>

(4) *Mediastino-pericarditis*.—In my time, a candidate for a final medical examination asked for the causes of greatest cardiac enlargement was expected to reply aortic stenosis, aortic incompetence, and adherent pericardium. It was understood that with the last, external adhesions (mediastino-pericarditis) might be necessary. I do not know how it is to-day, but I could not now agree with this answer. It is now certain that adherent pericardium is seldom a cause for enlargement at all, even if so complete and considerable as to be calcified. External adhesions of any moment are so rare that they are unworthy of the attention they have curiously attracted in the past. As Wenckebach<sup>114</sup> showed, they may disturb respiration as much as they hamper the heart. In Smith and Willius's series, among 8912 necropsies were 144 cases of adherent pericardium. Among them 12 showed fairly extensive adhesions to surrounding structures, and of these, only 3 were uncomplicated—i.e., unassociated with valvular or other heart disease.

Dr. William Evans has kindly abstracted for me

figures on the incidence of adherent pericardium as a cause of cardiac enlargement from the records of the pathological department of the London Hospital by courtesy of Prof. H. M. Turnbull.

In a series of 10,000 consecutive necropsies in which the heart was examined, fibrous adhesions between the visceral and parietal layers of the pericardium had obliterated the pericardial space in 83 cases. Calcification of the pericardium was present in 8 of these, but it was only a prominent feature in 2, while in the remaining 6 it was present as scattered plaques. Extrapericardial adhesions were only described once, and even in this instance they were not extensive. Although it is unlikely that extrapericardial adhesions were absent in each of the other 82 cases, it is improbable that they formed a noticeable feature in any.

Attention was paid to the weight of the heart and to the condition of the valves and heart chambers. If the weight exceeded 12 oz. in the female or 13 oz. in the male, or if hypertrophy of the heart chambers had been described at necropsy, cardiac enlargement was assumed to be present.

In 34 of the 83 cases the heart showed no abnormality; it was not enlarged and the valves were healthy. Cardiac enlargement of varying extent was present in the remaining 49 cases. In 3 of these, enlargement of the right ventricle had followed chronic lung disease, and in another 3 the left ventricle was enlarged from hypertension. In the remaining 43 cases, rheumatic valvular disease involving the mitral, aortic, and often the tricuspid valves, accounted for the presence of cardiac hypertrophy both in its extent and distribution. In each individual case Dr. Evans formed the opinion that the cardiac hypertrophy was wholly due to the valvular lesion and that the presence of adhesive pericarditis was in no wise a contributory factor.

Whenever considerable or gross enlargement of the heart has been found on clinical examination without causal hypertension or aortic incompetence, we have in the past too readily attributed it to adherent pericardium. We have entertained the diagnosis of adherent pericardium too often, and of grossly enlarged auricles with fibrillation too seldom; though the frequency with which aortic valvular disease is a participant or sufficient cause of cardiac enlargement has not been exaggerated. When a high grade of mitral stenosis is present, and auricular fibrillation supervenes, the collapsing pulse and the diastolic murmur of aortic incompetence frequently disappear. It seems to me likely that some of the cases, now increasingly reported, of aneurysmal dilatation of the left auricle in mitral stenosis may have erroneously been ascribed to concurrent adhesions. Crighton Bramwell<sup>17</sup> noted and tabulated the incidence of pericardial adhesions in reported cases of aneurysmal dilatation of the left auricle, but examined and rejected the evidence that they are an important factor in determining it.

#### Dilatation of the Heart

Acute dilatation has gradually lost its original significance in a clinical sense, and is now a superfluous term in so far that it is never now maintained that heart failure is due to acute dilatation or synonymous with it. It should be strictly dissociated from any clinical features, whether symptoms or signs, which have been supposed to indicate or coincide with it. It will be an excellent thing if we abandon even in our terminology the idea that clinically the heart can dilate like a balloon in a few minutes or a few hours and thereby induce an abrupt and grave attack akin to heart failure. There is no reason why a sinister meaning should be attached to a change in size; and to reach any agreed and profitable conception, size must be clearly separated

from symptoms. Once "acute dilatation" is out of the way as a clinical term, we may proceed to inquire whether as a simple fact the heart is capable of acute dilatation or acute distension, or, as we might almost now say, rapid enlargement. Admittedly, the heart, even the healthy heart, can and often does dilate. Thus after an extrasystole which fails to eject the usual amount of blood from the ventricle, the heart is overfilled and dilates so much that by radioscopy it can be seen to halt and then to swell. This accounts for the large volume of the returning or subsequent radial beat. Another example of the possibility of dilatation is Müller's experiment where at the end of normal expiration the breath is held and an extreme effort is made to inspire against obstruction. This increases the negative intrapleural pressure with a resultant temporary "acute dilatation" though a harmless one, and it can be confirmed by teleradiogram.<sup>26</sup> Apart from such almost physiological but rapid changes in the heart volume, the question has been definitely raised,<sup>48</sup> is there such a thing as an acute temporary dilatation of the normal heart? Without attempting a full answer, we may consider certain cognate subjects bearing upon it.

(1) "Acute dilatation" from a particular act of exertion appeals more to the lay than to the medical mind. Medical opinion is now firmly opposed to the idea that the healthy heart in a healthy man can be injured by physical strain. Many have been keenly watching, as Mackenzie did but without success, for a patient with a disability acquired solely in this way. Usually, the alleged cause is trivial or impossible; often symptoms began some hours (even a day or so) after the exertion which is blamed; though, as Mackenzie used to say, the heart does not remember. There is remarkable agreement that the heart is often a trifle smaller (or at least narrower) after exercise than before. To take an example, McCrea, Eyster, and Meek,<sup>77</sup> spared no pains in the care with which they recorded the effect of exercise on diastolic heart size, and concluded that such variation as the heart undergoes during exertion is slight, that its size may remain unchanged or increase or decrease slightly. It is evident that there may be temporary adjustments; but the immediate effect of exercise on the heart's volume is insignificant, and this applies even where the test exercise has been extreme and prolonged.

Leaving the question of the immediate effect, it might be that the effect of prolonged and recurrent exertion would be to produce enlargement of the heart. Here we have at our disposal in the literature regular series of direct observations made upon athletes which have appeared in various countries, in this country by Crighton Bramwell and Ellis.<sup>18</sup> The heart of an athlete may be somewhat larger than the average in relation to body-weight in particular forms of sport of which swimming, wrestling, and cycling may be mentioned. Such enlargement is not to be regarded as abnormal, rather may it be counted supernormal, as, for instance, in successful Marathon runners.

The ultimate effects of persistent devotion to athletics is a matter of perhaps even greater interest. The crews of the first twenty-four Oxford and Cambridge boat races up to 1869 were followed up by Morgan, and he found that there was little appreciable difference in the mortality from heart disease among them when compared with men of a corresponding age.<sup>82</sup> So far as I know, no one has published any satisfying series of soldiers proved to have permanent cardiac injury as a result of physical strain

in war. The "soldier's heart" was not enlarged, though the accompanying tachycardia often gave the illusive impression of enlargement at the apex-beat.

(2) *Paroxysmal tachycardia* has often been cited as a good example of acute dilatation, or, as we had better say, rapid enlargement of the heart. It is nature's own experiment not only on cardiac enlargement, but on pure myocardial failure; and it was partly from his observations on the failure resulting from prolonged tachycardia that Mackenzie disliked the idea of back pressure as it used to be taught. In most subjects the heart is sound, but liable to sudden bouts of extreme tachycardia. Although it has been said that enlargement quickly occurs—e.g., some hours after an attack begins—I have been unable to confirm this in a few such cases examined by X ray. Yet there is no doubt that with persistence of a paroxysm there may be enlargement of the heart with evidence of cardiac failure in all its stages. The earlier observations of Dietlen<sup>29</sup> and others<sup>67</sup> have been fully confirmed. Some time ago I had the opportunity of watching the development of enlargement in a patient whose attack lasted under observation for 21 days. By that time there was some enlargement, though not extreme, but the cardiac silhouette was obscured by pulmonary congestion and small bilateral hydrothorax.

Similar conclusions apply also to paroxysms of, or the onset of, auricular fibrillation and flutter. I have not recorded any rapid enlargement within a few hours or even days of the onset in cases I have observed. As the condition begins to derange the circulation, then we begin to see the effect on size also. It is rather the length of time taken to produce demonstrable enlargement than the rapidity with which it occurs that has impressed me (Fig. 8); see also.<sup>39</sup> It can easily be shown that the enlargement of the left auricle in mitral stenosis is not a sudden occurrence, for it can be followed in its gradual enlargement over years (Fig. 9).

(3) The rapidity of the enlargement which may take place in the course of acute *cardiac rheumatism* is of perennial interest and importance, though its degree and frequency are far from being known. Confusion with a pericardial exudate aside, the part played by a previous attack and early mitral stenosis is always difficult to exclude or appraise when judging enlargement from myocarditis alone. Thus cases become important which are proved post mortem to have no endocarditis although they have died from severe carditis.

Such have been collected and discussed by Garber,<sup>41</sup> who found in the literature 17 cases in which the diagnosis of rheumatic carditis was found at autopsy and in which apparently all the heart valves were free from endocarditis. He adds an additional case, and another has recently been reported in an interesting paper by Bland, Paul White, and Duckett Jones.<sup>14</sup> Incidentally, these workers also discuss the occurrence of a mid-diastolic murmur at the apex in rheumatic cases where mitral stenosis was absent and where the cause of it could only be ventricular dilatation. The mitral valve in Bach and Keith's important case<sup>4</sup> was not stenosed, yet the left auricle was very large.

No one can doubt the rarity of this rheumatic carditis without endocarditis, so the original problem remains: how to exclude the effects of previous valvulitis or active valvular disease in deciding the presence of rapid enlargement during an attack of rheumatism. As indicated, percussion and the position of the apex-beat under these circumstances afford uncertain evidence. What is required is radiographic evidence that the average patient in a first

attack of rheumatism with the heart affected does, in fact, show early enlargement from acute myocarditis. That evidence appears to be still wanting, and until it is forthcoming we must be content with the clinical data which are adequate for the purpose of a relevant diagnosis.

Many other infections besides rheumatism have been said to cause acute cardiac dilatation, but generally the statement has been founded on a combination of unreliable physical signs in the presence of a heavy infection. But radiological studies have not yet shown that in these various infections, such as pneumonia and diphtheria, actual

upon the height of the diaphragm, and in failure it is a real bar to a ready judgment on increase or decrease in size. Probably it is the chief factor in producing that outward displacement and recession of the apex-beat which as students we had to watch in the course of failure and recovery. No longer can this apex-positioning be accepted as clinical proof of enlargement. Again, the frequency of hydrothorax in failure is scarcely appreciated until such patients are examined radiologically by routine when they come to hospital in failure; indeed hydrothorax may have a profound effect upon the apparent size of the heart or may swamp the heart almost completely.

FIG. 7.—Calcification of pericardium. Left (II) oblique position.

FIG. 8.—Mitral stenosis. Outline of telerradiogram, anterior view. Dotted line: five years later and after auricular fibrillation for one year.

FIG. 9.—Mitral stenosis. Outline of telerradiogram, right (I) oblique position. Barium in oesophagus shows slight enlargement of left auricle (continuous line), and greater enlargement five years later (dotted line). Same patient as Fig. 8.

dilatation of the heart occurs in any material proportion. In pneumonia we are fortunate in having the results of a recent detailed study by radiological means in the work of Davies, Hodgson, and Whitby,<sup>27</sup> carried out with the support of the Royal College of Physicians. They kept close watch for changes in the heart, but in the whole series of 119 cases found only 3 patients in whom there was any definite change in its size. In these 3 cases, too, there were no clinical symptoms suggestive of cardiac disability, and all had a relative bradycardia. It is unnecessary to view such a bradycardia as an indication of a myocardial defect as it is too common a finding in normal convalescence, both from infections and from parturition, indeed many have looked upon it as a favourable sign. Besides, bradycardia itself is a sufficient cause for a slight increase in heart size as Rösler<sup>28</sup> confirmed.

(4) The remaining condition which has to be considered from this standpoint of rapid enlargement is that which may occur with acute *congestive heart failure*. At once I must admit that even with radiological aid it is no easy matter to decide. The first difficulty is that it is so rare for a heart of normal size to fail at all, though Nemet and Gross<sup>24</sup> found that out of 89 cases of failure there were 3 in which the heart post mortem was found to be free of hypertrophy—i.e., of normal weight, which is of course not the same thing as normal volume. We must assume, therefore, that the heart in failure is enlarged. The other great difficulty is the fact—which is not yet sufficiently realised—that one of the early effects of failure is raising of the diaphragm from hepatic and other abdominal distension inseparable apparently from failure of this kind. We have seen how much the position and apparent size of the heart depend

Friedman and Strauss<sup>40</sup> studied 21 cases of cardiac failure by X ray methods during recovery and found that there was no change in size in 35 per cent., a decrease in all diameters in 35 per cent., and a decrease in one border only, generally the right, in 30 per cent.

For some years Dr. Bedford and I have collected from time to time orthodiagrams or telerradiograms of patients before and during failure, or during failure and afterwards, to see what happens to the heart size, and we have found nothing to support the old notion that anything in the nature of an acute dilatation occurs with ordinary heart failure. The difficulties have been indicated, but we are satisfied that rapid change in size is always slight if it can be demonstrated at all. With the clinical sign of venous engorgement in the neck, one would expect to find by X ray distension of the superior vena cava and of the right auricle, and this is probably the main alteration which does take place in the outline of the heart in simple failure. This is but a fragmentary statement about the radiology of heart failure where pulmonary congestion often dominates the situation. Such enlargement of the heart as does occur in failure is mostly from congestion, producing the so-called mitralisation of the heart. In failure there is change in shape and position rather than change in size (Figs. 10 and 11).

### Hypertrophy

It will be evident that I am not so placed that I can with any profit to you inquire far into the physiological and pathological theories and views about hypertrophy and the mechanism of its production. The opinion which has prevailed and still prevails is that hypertrophy is a response to increased demand—

a work-hypertrophy. Starling showed that dilatation is an essential physiological adjustment to increased work. Hypertrophy may then follow to meet a persistent demand on the heart.

From time to time other causes are advanced, and Sir Thomas Lewis,<sup>69</sup> from his early but unsurpassed examination of the relative weights of the ventricles, formed the opinion that mechanical factors are by

FIG. 10 (above).—Hypertension. Congestive failure. Note raised diaphragm, horizontal heart, congestion of hilar vessels.

FIG. 11.—Same patient. Recovery from congestive failure. Note descent of diaphragm, more vertical heart, absence of hilar congestion.

no means the only important causes of hypertrophy; and Cotton's work<sup>25</sup> supported it. Toxic substances are said directly to stimulate the heart muscle-fibres to hypertrophy,<sup>105 106 86</sup> and prolonged thyroid feeding to lead to hypertrophy.<sup>118</sup> Lewis and Drury,<sup>71</sup> from their observations on arteriovenous aneurysm and the enlargement of the heart which accompanies it, suggested that diminished coronary flow and under-nutrition might be the cause of enlargement,

not only in that condition, but also in others such as severe anæmia and narrowed coronaries. Some experimental support for this attitude has been produced.<sup>100</sup> Wiggers<sup>117</sup> feels that there is no evidence that changes in quality or quantity of blood-supply, or the presence of toxic or infectious agents, can themselves induce muscle growth, but probably do so by disturbing function and leading to increased diastolic length. This hæmic or toxic origin of hypertrophy is not merely of academic interest, for it has recently gained prominence among those interested in the question of cardiac hypertrophy in coronary lesions. Willius and Smith<sup>119</sup> examined the hypotheses and favour that of increased work, as do Nemet and Gross.<sup>84</sup>

Assuming that for the most part hypertrophy is a response to increased work, let us see where the change in muscle mass or bulk occurs to meet the demand. Karsner and his co-workers<sup>54</sup> confirm by accurate study the belief that it is due probably to hypertrophy of the individual muscle-fibres without an increase in the number of fibres. All fibres tend to approximate to the larger size, and they suggest that when all or nearly all the fibres have attained the maximum, further hypertrophy or compensatory development is impossible. This raises the pertinent question of what else does or can limit the response by hypertrophy. It has been said that a limited blood-supply may do so (but see Lewis and Drury<sup>71</sup>); Russow<sup>84</sup> says that undoubtedly the

supervention of functional disabilities such as auricular fibrillation may so act.

In a clinical sense, hypertrophy is a life-saving and beneficial process; almost one might say that the heart enlarges as it ought to do under adverse circumstances. A good example of physiological hypertrophy is the increase in the relative size of the left ventricle after birth, for the child is born with right and left ventricles of the same wall thickness. The blacksmith's arm and the athlete's heart are admirable examples of purposive adjustments.

When the weight of the heart exceeds about 300 g. in a man and 250 g. in a woman, the limits of normality are approached. Ready figures in use in England as a limit of normal weight would be 11 oz. (or 330 g.) in men and 10 oz. (300 g.) in women. Weighing of the ventricles of the heart separately<sup>69</sup> and exacter measures of the size of the auricles will be needed as a regular pathological routine if radiological findings in life are in future to be properly correlated at death. Of course, weight is easier to estimate than volume if only because of post-mortem changes, but volume mensuration would be invaluable. Paul White<sup>115</sup> has made some trenchant remarks on the limited value of post-mortem tables of heart weights which are so often the end-results of completed disease.

Although under favourable circumstances one might regard hypertrophy as a responsive strengthening of the heart, as e.g., in the overloading of hypertension, yet in practice this is seldom true, and for two reasons: first, associated disease in the coronary arteries with consequent lesions of the myocardium, old or recent or both; second, the persistence or increase of the peripheral obstruction which initiated the enlargement.

#### THE INFLOW AND OUTFLOW TRACTS IN CARDIAC DILATATION AND HYPERTROPHY

In 1930 Kirch<sup>58</sup> published a full statement of his findings and views upon ventricular hypertrophy, and in 1934<sup>59</sup> he published some further observations and reference to experimental work in support. His earlier papers on the subject may also be consulted.<sup>60 61</sup>

His researches were conducted by exact weighing of the separate chambers and septa of hypertrophied hearts by Müller's method, and also by linear measurements of the chambers. By these means facts were assembled not only on the weight, but on the volumes of the chambers, the ventricles in particular. Apart from normal controls, the hearts of patients with non-valvular heart disease alone were studied, mostly pulmonary heart disease (for right ventricle) and hypertension (for left ventricle). He found that, taking a single ventricle, the process of dilatation (and hypertrophy) always began in a particular portion of it, and only later was the rest of the ventricle implicated. So he distinguished in each ventricle two separate functional portions, and called them the inflow and the outflow tracts.

Taking the right ventricle, which illustrates his views best and has been most fully worked out, the inflow tract extends from the tricuspid orifice to the apex and comprises the posterior wall of the right ventricle and septum adjoining. The outflow tract extends from the apex to the pulmonary orifice and comprises the anterior wall of the right ventricle and adjoining septum. Every dilatation (and hypertrophy) begins in the outflow tract and is characterised by lengthening of the outflow moiety of the ventricle. This lengthening of the anterior portion of the right ventricle is betrayed by prominence of the conus—i.e., the far end of the outflow tract. There is also some favorotation of the heart on its long axis.

When the inflow tract is affected, and it is never affected until later when the outflow tract has acquired its characteristic change, it is a widening or broadening of the inflow portion of the ventricle which occurs. In other words, late stages of hypertrophy and dilatation of the right ventricle involve the posterior and apical portions, and the ventricle broadens. It is only with the supervention of chronic congestive failure that the right auricle and eventually the left ventricle will show consequent change.

These principles are applicable also to dilatation and hypertrophy of the left ventricle, where lengthening of the outflow tract with early change in the sub-aortic region is described, though it is less easily demonstrated than in the right ventricle.

It will be a long time before these detailed studies find their correct place in pathology, though they seem important and likely to stimulate progress. It is doubtful, however, whether Kirch is right in trying to adjust Moritz's "tonogenic" and "myogenic" conceptions to these pathological findings of an outflow and an inflow tract. From a radiological standpoint, they do seem to explain in fair measure the changes we have found—e.g., in emphysema. The bearing of Kirch's research on radiocardiology has already been noticed by certain workers, Kudisch<sup>64</sup> Zdzansky,<sup>120</sup> and especially Nemet and Schwedel.<sup>65</sup>

In my next lecture I hope to speak on clinical enlargement chiefly as it affects the separate chambers of the heart.

## THE TREATMENT OF ANORECTAL WOUNDS\*

BY W. B. GABRIEL, M.S. Lond., F.R.C.S. Eng.

SURGEON TO ST. MARK'S HOSPITAL AND THE ROYAL NORTHERN HOSPITAL, LONDON

In the surgery of the lower rectum and anal canal difficulties have to be contended with which render primary suture of wounds unusually liable to failure. The difficulty in sterilising the anal skin, the risk of subsequent faecal contamination, the movements of the sphincter, and the poor vascularity of the subcutaneous tissues all tend to spoil the results of aseptic surgery. In practice it is seldom advisable to attempt primary suture of wounds in the anal region unless they fall short of the anal margin and the anal canal. The commonest indications for primary suture occur after excision of the coccyx for cure of coccydynia, and excision of postanal dermoid fistulæ.

A great saving of time is effected by a successful suture of these wounds when compared with the time taken for healing by granulation; dermoid fistulæ are suitable for excision and suture if they are free from active suppuration and if the sinuses are in the middle line. In suturing these wounds a few deep sutures must be placed with the object of obliterating the depth of the wound, and are tied over a roll of gauze after suturing the skin with interrupted mattress sutures. Buried catgut ligatures should be avoided, any hæmorrhage being stopped by forcipressure or twisting. A firm dressing is applied over the anchored dressing and is kept in position by transverse strips of Elastoplast. The bowels are subsequently kept confined for six or seven days and the sutures are removed between the sixth and eighth day in order to prevent them

cutting through and producing stitch sinuses. A recent case has been that of a man aged 26 with a dermoid fistula presenting three or four sinuses. It was excised and sutured; the wound healed by primary union, and he was discharged from hospital on the fifteenth post-operative day. Healing by granulation would have taken at least five weeks.

I have found by experience that primary suture is not likely to be successful if secondary openings have formed at a little distance left or right of the middle line; in these cases so much skin must be excised in order to remove the lesion completely that the wound cannot be sutured except under tension, and it invariably breaks down.

Primary suture is also required in the treatment of certain tumours in this region. Anal lipomata are suitable for enucleation and suture of the resulting wounds. I have excised a sacrococcygeal chordoma the size of an orange, and the resulting deep wound was closed by primary suture over an anchored dressing; it healed cleanly.

In operations for anal fistulæ primary suture is now seldom attempted. The only type for which suture could be contemplated is the short direct fistula; this usually arises in the anal canal and after primary suture there is a considerable risk of infection and breaking down at the anal extremity of the wound; if this takes place the patient is left with an ulcer at the anal margin which is unlikely to heal until it is drained externally. In order to save the disappointment and delay of such a setback the method of incision and laying open of fistulæ is now universally adopted.

### HEALING OF ANAL WOUNDS

Healing by granulation is the only certain method of obtaining sound healing of wounds extending into the anal canal. In order to procure consistently good results in this region of the body the surgeon must set out deliberately to leave open wounds of such a shape and size that healing by granulation will take place, and he must be prepared to organise and supervise the after-treatment with this end in view. An anal wound cannot be considered to be finished from a surgical point of view until it is healed and has been proved to be capable of withstanding the ordinary stress and strain of active life.

A wound in the anal canal must be drained externally, and if the resulting wound be considered to be partly internal—i.e., that part which is within the grasp of the sphincter muscles—and partly external, it is invariably found that the internal part heals more slowly than the external part. This is particularly true of wounds in the middle line, whether anterior or posterior to the anus, and is due partly to the squeezing up effect of the external sphincter which tends to prevent proper drainage of the anal extremity of the wound, and partly to the increased tendency of the soft parts externally to fall together.

Drainage of an anal wound is made effective by *cutting away skin* and this is really the basis of all rectal operations. The anal skin is very lax; it is liable to become swollen either from œdema or from underlying congestion or thrombosis of the anal veins, and with experience one learns that excision of a certain amount of skin is essential for maintaining drainage, and it is also one of the best ways for sparing the patient post-operative pain.

In order to provide more adequate external drainage than would be given by a linear or oval wound, which would require plugging to keep it open, it is customary to aim at leaving a racket-shaped or

\* Address given to the Manchester Surgical Society on Jan. 21st.

triangular wound, the broadest part of the wound being external to the anal margin. This principle of excising skin is applied with advantage in almost every anal operation; its greatest value is seen in the case of abscesses, anal fissures, and fistulæ. Any form of anorectal abscess which points externally is well treated by excision of the entire skin covering it—the so-called scalping operation. Care is taken not to cut the external sphincter and complete drainage is given so that as a rule all the anal abscesses, and at least half the ischio-rectal abscesses, heal without a second-stage operation.

In the case of anal fissures and fistulæ the area of the external wound must vary according to the particular case, but as a working rule it may be said that the deeper the fissure and the more difficult the fistula on account of deep tracks or submucous pockets, the more adequate must be the external drainage. The cutting back of a fistula wound into healthy tissues is commonly known as "Salmon's back-cut" and is still the basis of most fistula operations. It may be of interest to repeat the words of a visitor to St. Mark's Hospital in 1857, two years before Salmon, the founder of the hospital, retired: "One of the features which must strike a looker-on at St. Mark's is the very great freedom with which the knife is employed. In the operations for fistula and for fissure Mr. Salmon makes very free and deep incisions; and, indeed, his rule in the former of cutting the base of the sinus as well as the sphincter, necessarily involves an extent of incision at least three times that usually employed." This tendency to make large external wounds has been handed down from one generation of surgeons at St. Mark's Hospital to another, and this is good presumptive evidence that the method is a sound and practical one for these difficult cases.

#### USE OF TANNIC ACID

Granted that an anal wound is made of the requisite size and shape, it must be maintained so after operation; if by some mischance the wound margins fall together so that the external surfaces adhere, the area of external drainage may be greatly reduced in size within a few days. As has already been mentioned, this is particularly liable to happen with midline wounds. Premature external healing of the wound is likely to result in incomplete healing; there are two ways in which this tendency can be minimised.

1. *Cauterising or coagulating the wound surfaces.*—This can be done with the actual cautery or diathermy electrode or by application of strong nitric acid. A better method, and one of which I believe this is the first report, is by the application to the wound, at the conclusion of the operation, of a strong solution of tannic acid. A 20 per cent. solution of tannic acid in 1 in 1000 flavine was introduced by Wilson,<sup>1</sup> of Edinburgh, for the treatment of burns, and an even stronger solution of tannic acid, 40 per cent. in flavine, has been used in the Royal Northern Hospital for the same purpose. A single application to a burn produces a firm coagulum, and it has proved most satisfactory in the treatment of burns generally. It occurred to me that this might prove to be very useful for rectal work. When a fissure or fistula wound has been made at operation, hæmostasis is effected by forcipressure, and then the tannic acid solution (40 per cent. in flavine) is applied for perhaps two minutes on gauze swabs; a brownish-yellow surface coagulation is soon produced. The operation is completed in the usual way by injection

of sterile vaseline into the lower rectum and insertion of a tube and a gauze dressing moistened in Dettol lotion ( $\frac{1}{2}$  oz. to 1 pint). I have done this for more than 50 fissure and fistula cases and am convinced of its value; not only do the wounds keep flat but the patients tend to have less pain than formerly, and the dressings come off quite easily on the third day leaving a flat wound of the same shape and size as when the operation was completed.

2. The other way in which the risk of premature and therefore incomplete healing may be minimised is by *insertion of a firm flat dressing* at the time of operation, and keeping it in position until the third day. In this way the skin margins are kept back; when the dressing is changed down to the surface of the wound on the third day and subsequently, it is usually easy to keep the outer part of the wound flat. If, unfortunately, the original dressing is inserted insecurely or comes out prematurely when the tube is removed, it is often difficult to reintroduce a dressing so advantageously as at the operation.

Some writers have decried the insertion of gauze dressings into the anus, but in the treatment of fissures, fistulæ, hæmorrhoids, or any condition where a wound is left at the anal margin, I consider that a moist gauze dressing properly tucked in, with a firm pad of gauze and wool retained by a T-bandage, is essential for correct healing.

#### MANAGEMENT OF THE EXTERNAL SPHINCTER

It is often advisable to stretch the external sphincter at the beginning of, or in the course of, a rectal operation; pre-operative spasm of the sphincter is one important indication, and another indication is often afforded, after administration of a low spinal anæsthetic, by noting that the sphincter has failed to relax properly; this is usually due to a fibrous infiltration of the contracted sphincter. A sphincter of this type may be restored to normal by a careful stretching, but often, as in the course of operations for chronic fissure, the subcutaneous portion of the external sphincter needs incision.

The stretching of a sphincter has been alleged by some authorities to cause severe post-operative pain. This has not been my experience. I think possibly the results vary according to the anæsthesia employed. If a light general anæsthetic is used it is difficult to stretch a sphincter; it has to be done quickly, forcibly, and probably incompletely, whereas if a low spinal is given three to five minutes can well be taken up in a careful and graduated stretching until four fingers are readily introduced. The stretching effect should be chiefly posteriorly and tight fibres should be ruptured here rather than anteriorly.

If a tight sphincter is well stretched the patient is likely to be free from post-operative spasm and involuntary contractions of the muscle, which are not only painful in themselves but render the subsequent dressings difficult and painful. A relaxed sphincter means comfort, and as an alternative to stretching, in certain nervous subjects with pre-operative sphincter spasm, one of the oil-soluble anæsthetics may be employed (such as A.B.A., B.A.B.A.N., Procaine or Percaine in oil<sup>2</sup>) in addition to the main anæsthetic (general or low spinal) which may have been selected. When the patient has been placed in the lithotomy position ready for the

<sup>1</sup> These are solutions of local anæsthetics in sterilised almond oil; the use of oil as a solvent serves to delay absorption and to prolong the anæsthetic effect. The first three solutions mentioned contain anæsthesin or butesin in addition to which B.A.B.A.N. (Martindale) contains 1 per cent. of basic novocain, and procaine (Allen and Hanburys Ltd.) contains 1.5 per cent. of procaine base. The percaine in oil is a 0.5 per cent. solution and contains also 1 per cent. of phenol.

<sup>2</sup> Wilson, W. C.: Edin. Med. Jour., 1935, xlii., 177.

operation, as a first step 5-10 c.cm. of the oil-soluble anæsthetic is injected into the sphincter under aseptic conditions through a median puncture about one inch posterior to the anus.

It is often necessary to divide the subcutaneous portion of the external sphincter. In every case of anal fissure which has reached the chronicity which calls for operation, this portion of the sphincter must be divided and stretched. This can be done in any anal quadrant with impunity, and according to the incidence of anal fissures is most commonly required posteriorly, less often anteriorly or laterally.
